CINNAMON CHIPS.—Only a small proportion of the 300 packages offered for sale was disposed of at 4½d to 6d per lb for quill and cuttings, and 2d for common chips.

QUININE.—After having been quite lifeless until the middle of the week, German bulk, being offered at 1s 4d per oz., but finding no buyers at that price, the agents for the B & S brand reduced their quotation to 1s 3½d per oz., at which on Wednesday they sold 10,000 oz. for October delivery.—(Continued on p. 262.)

THE AMSTERDAM CINCHONA AUCTIONS. (Telegram from our Correspondent.)

AMSTERDAM, Aug. 30th.—Of the 2,791 packages cinchona bark offered for public sale today 2,466 were disposed of, with fair competition, the unit ranging from 10c to 11c per half kilo, or 11-5thd to 2d per lb. exactly at par with that of the London auctions of the day before yesterday. The principal buyers were the Auerbach quinine works, and next to them the Brunswick factory. The prices obtained run as

follows:—Druggists' bark in quills, broken quills and chips, 20c. to 72c. (=3½d to 1s 1d per lb.); ditto, root, 23c. to 30c. (=4½d to 5d per lb.); manufacturers' bark quills, broken quills, and chips, 9c. to 103c. (=1½d to 1s 6d per lb); ditto, root, 17c. to 80c. (=3½d to 1s 2½d per lb.)—*Chemist and Druggist.*

THE DUTCH MARKET.

AMSTERDAM, Aug. 29th.

CARAWAY SEED.—The wretched rainy weather has much damaged the growing crop. The quality is bad, and farmers ask high prices, 13½f. to 13f. per 50 kilos. for new seed. Old seed, the quality of which is much superior to the new, is held on 16f., which price is said to have been paid in some instances.

CINCHONA.—The next auction here, to be held on August 30th, will contain 506 cases and 2,215 bales Java bark, and 40 bales Ceylon bark, consisting of: Succirubra, quills, 218 cases; broken quills and chips, 29 cases, 87 bales; root, 49 bales. Ledgeriana, quills, 54 cases. broken quills and chips, 83 cases, 1,633 bales; root, 347 bales. Calisaya Schukkraft, quills, 32 cases; broken quills and chips, 44 bales; root, 11 bales. Hybrid, quills, 29 cases; broken quills and chips, 53 cases, 27 bales; root, 8 cases, 9 bales. Officialis, broken quills and chips, 9 bales; root 12 bales. C. Anglica, broken quills and chips, 7 bales; root, 10 bales. Ceylon, broken quills and chips, 40 bales; weighing together 217 tons, of which 186 tons are manufacturers' bark, containing the equivalent of 18,815 lb., or 4½ per cent. sulphate of quinine on the average. From these 186 tons manufacturers' bark about 12 tons analyse 1 to 2 per cent. s. q.; 33, 2 to 3; 31, 3 to 4; 46, 4 to 5; 30, 5 to 6; 27, 6 to 7; 23, 7 to 8; 13, 8 to 9; 3, 9 to 10; 2, 10 to 11. There are thus 110 tons above the 4-per-cent. standard alluded to in my former letters, in which I state as my opinion that the 4-per-cent. standard is the vital question of a successful plantation of cinchona trees.

CUBEBS.—Fifteen bales of cultivated cubebs of good quality, recently imported from Java, are firmly held at 3f. 50c. per ½ kilo. (= 30f. per cwt.), whilst usual genuine berries may still be had at the equivalent of 27f. to 28f. per cwt. There is not much left of the last crops, and at least six months must pass before the new crop may be expected. The price last paid for spurious cubebs (big grain) was 295f. per 50 kilos, or 2d. 15s. per cwt.—*Chemist and Druggist.*

THE JAVA COFFEE CROPS.—Says the Hamburg correspondent of the *London and China Express*, writing on Aug. 15th:—Some figures have been published lately regarding the coffee crops of the past year and former years in Java. In 1887 the Government crop was not more than 5,280,000 piculs, a quantity which is very small when compared with the crops during the last fifty years. Formerly a small outturn of the crop was always succeeded by a larger one in the following year. In 1864 there were gathered 70,000 piculs, but in 1865 940,400 piculs; in 1871 116,204 piculs, but in 1872 985,961 piculs. In 1875 the crop was 493,420 piculs, but in 1876 the outturn was abundant, being 1,266,196 piculs; and the crop of 1880 of 558,281 piculs was followed in 1882 by a quantity of 1,007,000 piculs. The prospect for the crop of this year are again unfavourable, which will greatly injure the interests of those concerned in the cultivation, and especially of the native population, the revenue of which are already very small. In the years 1881, 1882, 1883, and 1884 the population in Java earned about 14 million guilders by cultivating Government coffee, but the amount was only four millions in 1887, while the Government revenue sustained also a considerable loss. Under the present circumstances the question is being asked, what should be done to improve this gloomy condition, and from various sides it is urgently advised that such measures should be introduced as may lead to the benefit both of the Government and the native population.

THE ABSENCE OF BEACH IN CEYLON.

A correspondent addresses to us a query as to the cause of the absence of beach on the shores of this island. The dealing with shifting beaches has been one of the questions which has much exercised the intelligence of the engineering profession in England, and correspondence of late proceeding in the home scientific journals has roused the curiosity of our querist, who desires to know what causes can be assigned for the almost complete absence of shingle along our coast lines, while most other countries—certainly those situate in Europe—are liberally provided with this means of defence against the erosion of their shores by the sea. At first sight the query put to us on this topic does not seem easy to answer. There is ample rock formation around our shores to furnish the *débris* which supplies the usual material for a shingle beach. The constant attrition to which fragments of rock detached and falling into the sea are subjected by the action of waves and currents would before very long produce that rounded form which is possessed by most of the shingle forming the beaches of the United Kingdom, and we should naturally expect to find that, after countless ages of sea action, there would be deposits of such stones in certain positions sufficient in amount to form a regular beach. And yet we cannot call to mind that in any of the visits paid by us to many points on the coast of this island we have ever seen what could with justice be termed a beach, such as the formation which receives that appellation at home.

At Point Pedro in the Jaffna Peninsula there is the best defined beach that is, perhaps, to be found in the island, and at Valvettiturai, but a short distance to the westward of Point Pedro, the old Dutch marine works have operated as groynes and have arrested the course of the travel of the shingle and caused a very considerable deposit. But with these two exceptions we cannot call to mind any locality along the whole of the coast of Ceylon which we could point to as having anything worthy of being denominated a beach. There are many places where fragments of broken shell and coral have been heaped by the action of the sea; but such deposits must be considered as apart from the immediate object of our correspondent's query, though doubtless these have been accumulated by the like causes as tend to the collections of shingle in other countries. But what is asked is the reason why shingle, as it is popularly known to Europeans, finds no place on our shores. What becomes of the *débris* falling from the high and rocky cliffs noticeable at such places as Trincomalee and, though less prominently, at Galle and other places on our southern shores? It at first occurred to us that there might be something in the currents peculiar to Ceylon which might furnish a reply to these queries; but then, as we find that there are large accumulations of shell and broken coral, such a hypothesis seems scarcely tenable as furnishing any conclusive reason for the phenomena under discussion.

Shingle, it is well known, travels along the coast of Great Britain in the direction of the most prevalent winds and currents. When these give place to what are exceptional movements, the shingle deposits due to the operations of nature during the greater part of the year disappear in part for the time being, but only to reappear when the normal set is resumed. There are two

causes which appear to us likely to meet the demand of our correspondent for some possible explanation of the denuded characteristic of all coasts, not alone those of Ceylon, in tropical countries. Shingle, as we have pointed out above, there must be. What becomes of it? Why do we not see it lying on our shores? Now there is no doubt that to the action of currents resulting from the inset and outset of tides much of the deposits on any shore must be accounted due. In the more northern and southern zones there are few localities where the ordinary rise and fall of the tide does not range between six feet and ten feet. Here in the tropics the ordinary range is rarely above 18 to 24 inches, while during spring tides that range is increased but to thirty-seven inches.* The result to this limitation, we should say, would be that the currents resulting from tidal action along an open shore must be greatly restricted in force. This may amply suffice to drive up and accumulate light fragments of coral and shell such as we have remarked are in many places observable around Ceylon, but it must fail in power to give travel to stones of the size which form a beach in the usual acceptation of the term. The second reason which suggests itself to us is the existence nearly all round our shores of a coral or breccia fringe, this lying very often but from one to two hundred yards from the absolute coast line. This must break the force of the waves and currents very materially, further adding to the weakness of these due to limited tidal range. They also probably act as natural groynes, and when they do not stay the travel of the shingle and retain it in deep water, they compel that travel to follow a course far out beyond the earth line, so that real shingle is a rare visitant to the sandy slopes which, as the rule, is the substitute in all tropical countries for the shingly beach of more northern latitudes.—So far as we are aware, our correspondent's query is the first notice taken of this peculiar characteristic of our shore lines. We have endeavoured to answer that query to the best of our ability, but we should say there are many scientists among us who could probably furnish us with other information and suggestions which might tend to a wider elucidation of the subject. We know that our rocks generally are specially liable to decomposition; and that by means of carbonate of lime held in solution in the sea water, sand and fragments of all kinds are re-composed into breccias of varied qualities from solid "sandstone" to loose aggregations of coral and cabook; but surely some of the more granitic fragments are worn and polished into pebbles instead of being absolutely disintegrated?

As having some bearing on the subject, we would attract attention to the paper we quote below from the Transactions of the Geological Department of India, which may throw some light on the curious geological question raised. If rounded, shingle-like stones are found in deep water off Colombo, they are pretty certain to exist outside the coral or breccia reefs elsewhere. The introductory note to the paper quoted was written some months ago when we read and marked the matter for extract. It has been waiting for a convenient season, and that has now arrived.

* We quote from our latest "Handbook" as follows, the experience of Mr. Kyle in respect of Colombo:—The range of tide during the north-east monsoon is from 5 to 37 inches, and from 5 to 30 inches during the south-west monsoon, and averages about 24 and 18 inches respectively. The extreme highest and lowest tides occur at full moon in April, when the tide falls to the zero of the gauge and rises 40 inches within twenty-four hours.

EXAMINATION OF NODULAR STONES OBTAINED BY
TRAWLING OFF COLOMBO, BY E. J. JONES, A.R.S.M.,
GEOLOGICAL SURVEY OF INDIA.

[We had not heard of the following paper contributed to the proceedings of the Asiatic Society of Bengal, until we found it quoted into the records of the Geological Survey of India. First remarking that it is interesting to learn that close to Colombo the sea deepens to 675 fathoms, or 4,050 feet, we would suggest that volcanic matter which has come floating from Krakatao and its neighbourhood into our seas in large quantities may, to some extent, account for the abnormal constitution of the nodular stones?—ED.]

The following account* of these stones is reprinted from the Journal of the Asiatic Society, Bengal, as being of more direct interest in these Records:—

"The nodules were obtained during a trawling operation off Colombo in water of 675 fathoms, and are stated to have been found associated with sand and mud, which formed a hard calcareous crust at the bottom of the sea, and a small quantity of which was forwarded with the specimens.

"The stones are irregularly rounded, and vary in shape from almost spherical to roughly cylindrical with rounded ends. The specimens received varied in size from 1—4 inches in length and $1\frac{1}{4}$ — $\frac{3}{4}$ inch in thickness. Externally, they are rough and mostly have one or two small excrescences of the size of a pin's head, and a few small pittings of about the same size; the colour is dirty light grey.

"On breaking them open, the fractured surface has much the appearance of an ordinary slate without the cleavage, and is of a much darker colour than the exterior. Running along the central line of a long cylindrical one which I broke open, there is a narrow vein of a brownish colour.

"A microscopic examination of a thin slice shewed merely a confused mass of aggregates resembling in their structure that of spherulites, such as occur in the so-called spherulitic lavas, with the remains of Foraminifera and Radiolaria disseminated throughout the mass. With ordinary light, little is to be seen except more or less radiating fibrous aggregates, but as soon as the section is observed between crossed Nicol's prisms the whole field is seen to be covered with little dark crosses with their limbs parallel to the planes of the prisms, and, on revolving the stage, the limbs of the crosses keep the same orientation whilst the section revolves.

"It is when thus observed that the aggregates are seen to be entirely distinct from one another, as each cross keeps to its one aggregate, and the crosses do not overlap; so that, by revolving the stage, the limit of each aggregate can be determined by tracing the path of the outer end of one of the limbs of the crosses.

"In the volcanic rocks in which this structure is known, it appears to be due to incipient crystallization in a glassy mass; and at first it might be supposed that these masses were of igneous origin. This idea, however, is untenable on account of the remains of Foraminifera (of several species, the most easily recognised of which are the globigerina) and Radiolaria which are sparsely scattered through the mass, and, in some cases, enclose a spherulitic aggregate. An indeterminate greenish substance, which probably consists of glauconite, is also seen scattered through the mass. The only difference that can be detected between the central vein and the portion between it and the exterior is that the aggregates in the central vein are much larger and the colour brown instead of green, and that it is unacted on by hydrochloric acid, which dissolves out some calcareous

carbonate from the other portion. As mentioned by Mr. Daly in his letter forwarding the nodules, these are very heavy, having a sp. gr. of 3.77 at a temperature of 30° C. as against water of 4° C. A qualitative analysis shewed the nodules to consist in great part of baric sulphate together with small quantities of calcic and strontic sulphates, small quantities of calcic and magnesian phosphates, aluminic silicate, calcic carbonate, and traces of iron, sodium, and manganese.

"Not having the time to devote to a complete quantitative analysis, I made, in order to arrive at an approximate estimate of the proportion of baric sulphate present, a determination of the sulphuric acid. An average sample from two of the nodules powdered and dried at 100° C. gave 82.5 per cent. of baric sulphate, the whole SO_2H_2 being calculated as SO_2BaO ". "This result is, however, of course too high, as a small quantity of the SO_2H_2 is combined with Ca. and Sr. in the form of calcic and strontic sulphates, though, from the results of the qualitative analysis, it is probably not much too high; and we may, I think, safely take 75 per cent. as the percentage of baric sulphate present.

In order to see whether the material was derived from the mud in which the nodules occur, and which also contained Foraminifera, I made a qualitative analysis of the mud, and found it to consist mainly of aluminic silicate, with small quantities of calcic carbonate, some iron, and a trace of manganese; there was also a trace of an alkaline earth which was not removed by boiling with hydrochloric acid and subsequent washing, but this, on spectroscopic examination, shewed itself to be lime.

"In spite of the negative result of the analysis of the mud, I am inclined to think, from the presence of the Foraminifera both in the mud and enclosed in the nodules, that the latter have been formed at the bottom of the sea either at the spot where they were found or at no great distance therefrom, though it is difficult to imagine how the material was obtained; but it is possible that a careful analysis of a larger quantity of the mud would reveal a trace of Barium, for sea-water contains a slight trace of this element.

"I cannot at present call to mind any instance of spherulitic structure occurring without the aid of heat.

"In volcanic lavas and in artificial glasses, it may be regarded as concretionary, or as resulting from incipient crystallization or devitrification around certain points or nuclei. The nuclei when they exist consist either of a granule or a minute crystal or crystallite, but most commonly no nucleus is discernible.*

"In this case, however, it would seem, that it must be due to slow segregative action; and, baric sulphate being very slightly soluble in water, the deposition would be very slow and may have been to some extent crystalline, at any rate sufficiently so to produce the same effect as incipient crystallization from a glassy mass."

A SCHOOL OF ENGINEERING FOR CEYLON.

The receipt from the Madras Government of the report on the working of the Madras College of Engineering during 1887-8 suggests to us the necessity that exists for such an institution in Ceylon. We have got a Medical College in Colombo which has proved a marked success, and we do not see why a college for training young men as engineers should not be equally successful. There are plenty of trained officers in the Public Works Department whose services could be utilized as lecturers, while there is the Government Factory available for the practical part of the training. We are sure that there are many young men who would be only too glad to have the opportunity thus offered them of becoming fitted for an engineering career

* Natural History Notes from H. M.'s Indian Marine Survey Steamer "Investigator," Commander Alfred Carpenter, R. N., Commanding. No. 5. On some Nodular Stones obtained by trawling off Colombo in 675 Fathoms of Water.—By E. J. Jones, A.R.S.M., Geological Survey of India. Journ. Asiatic Society of Bengal, LVI., Part II, No. 2, 1887.

without having to incur the expense of going out of the island. It is true that the report before us is not of a very encouraging nature, the students having been very unsuccessful at the examination and the numbers attending the College having fallen off greatly; but this is accounted for as follows:—

The slight decrease in the strength last year was attributed to mere ordinary fluctuations, but the facts disclosed this year evidently lead to the conclusion that the difficulty in finding employment under Government is one of the chief causes that has told so perceptibly on the strength of the College. The stricter rules now in force, as regards the award of certificates, the increased length of the courses, and the increased cost of the education afforded although unquestionably important factors, did not probably contribute so much to this decline as the cause above mentioned. As the College has hitherto been more or less a training institution for the Department of Public Works, it is not surprising to find the number of admissions fluctuating with the facilities which passed candidates have of obtaining employment under Government. But the Director is disposed to think that the introduction of the re-organization scheme in its entirety and the strengthening of the staff by two European professors will ultimately raise the College considerably in public estimation and thus increase the attendance. If the men turned out under the new scheme prove themselves superior to those educated under the old, the employers of labor will naturally prefer them, and the demand thus created will lead young men to resort to the institution. Until, however, the States compels Local and Municipal bodies to employ only technically-qualified Engineering subordinates, the usefulness of the institution must be limited and its cost to the exchequer be much greater than would otherwise be the case.

Of the 93 students who attended the classes in 1888, 7 were Europeans and Eurasians, 6 native Christians, 53 Brahmans, and 27 non-Brahman Hindus, there being no Muhammadans. As regards the social position of the students, it was found that a very small proportion belonged to the poorer classes, this fact justifying the conclusion that the fees charged were too high. If, therefore, a similar institution is organized in Colombo, the errors which have been committed in connection with the Madras College of Engineering should be avoided.

A REMINISCENCE OF DARJILING AND LILIES.—When we visited Darjiling in 1876 we met a Gloucestershire squire, a fine-looking tall man, who had been an officer in the Guards. This was Capt. A. J. Elwes, brother, we believe, or cousin, of Mrs. Talbot of Ceylon. He was employed, with the help of the flat-faced Lepchas, in making natural history collections in Sikkin, one of the most favoured regions of the world, midway between the heat of the North Indian plains and the cold of the Himalayas. We were naturally interested to learn that Capt. Elwes had been in partnership in a Darjiling tea estate with a Mr. Macdonald, a grandson of our old parish minister in the Highlands, the Rev. John Macdonald, "the apostle of the north." Young Macdonald (son of the second Rev. John Macdonald, Dr. Duff's coadjutor in Calcutta) had inherited heart disease, and, contrary to the protests of the dentist, got a tooth extracted under the influence of chloroform. He left his young wife in the ante-room, who next saw him dead in the dentist's chair. We learned that Capt. Elwes had, in his garden in Gloucestershire, the finest collection of lilies in the world, and we now find from a book catalogue before us, that he subsequently published a monograph on his favourite flowers, which is thus described:—

"**LILIES.** ELWES (A. J.) A Monograph of the Genus *Lilium*, illustrated by W. H. Fitch, with fine emblematic title-page by W. G. Smith, coloured maps showing geographical distribution, a splendid full-page photo-

graph of the North-West Himalayas (the native locality of *Lilium polyphyllum*), and 48 magnificently coloured plates, imp. folio, 27 1/2 6d, scarce, 1880.

"This is a magnificent volume, alike a credit to author, artist, and printer. The drawing and colouring, by Mr. W. H. Fitch, is done with inimitable skill and glows with life."

This is a book we should like to see. Is a there copy in Ceylon?

CEDRELA TOONA.—As our readers are aware, we have published in the *Observer* Dr. Trimen's most recent and most matured opinion as to the comparative innocuousness of the borer which occasionally affects the tender shoots of *Cedrela toona*. It is amusing as well as interesting, therefore, to find Mr. T. Farr writing in the following strain to the local "Times":—

Having carefully examined the toona borer myself, and having previously made the acquaintance of the coffee and tea borer, I was sceptical as to the dangerous nature of the former, and was fortunate enough, through the courtesy of a friend to obtain so valuable an opinion on the subject as that of Dr. Trimen, given about a year ago. Dr. Trimen says: "The toona will do no harm planted on a tea estate. It is true that the tree has suffered from the attacks of a small caterpillar which lives upon the pith of the young shoots, but this has nothing to do with the borers which live on wood and are the larvæ of beetles." This opinion should set at rest any doubts on this subject, and, as the toona tree is without exception one of the quickest growing trees ever planted in Ceylon, and is the very best wood for tea boxes, it is very satisfactory to know that we may plant the tree with perfect safety amongst our tea. I have a considerable number of these trees of all sizes, and only a few of them have been attacked by this caterpillar.

The ancient date and the second hand origin of Mr. Farr's quotation of Dr. Trimen's opinion does not detract from the value of that opinion, any more than Mr. Farr's loity pretence of ignoring more recent and explicit testimony lessens the value of his testimony in favour of a tree, the value of which (for timber, not for firewood) we have impressed on our readers.

A DESTROYED ISLAND.—Dr. Treub, the director of the Botanical Garden at Buitenzorg, Java, has published his experience with regard to the reappearance of vegetation upon the Island of Krakatau, which partly sank, and was wholly overwhelmed by the ashes and pumice-stone from its volcano during the violent outbreak of 1883. Three years after this date, Dr. Treub (on 26th June 1886) visited the island, and as he approached it he found that it was covered with vegetation to the very summit of the mountain. The plants could not have grown from the roots or seeds of those existing before the great eruption, for the toughest organism must have been destroyed by the excessive volcanic heat. The whole island was covered with a layer of ashes and pumice-stone from 3 ft. to 240 ft. thick. Nor could the vegetation, Dr. Treub thinks, have been introduced by man, for the island is uninhabited and difficult of access. It must have been by means of seeds carried thither by birds, the wind, or the currents of the sea that the new vegetation arose. It consists for the most part of ferns, of which eleven different varieties were found, and of single specimens of blossoming herbs, such as are found on coral reefs that have lately risen above the level of the sea. Dr. Treub has, however, found that the ferns were not the first living plants that had found nourishment on the destroyed island. Almost everywhere there were signs that the ashes and pumice stone had been covered by a thin layer of algae, which rendered the surface of the soil soft and capable of absorbing water. These microscopic algae prepared the way for the ferns, and the latter, in their turn, for the blossoming herbs.—*Aberdeen Free Press.*

TEA CULTIVATION IN JOHORE.

Dear Sir,—I had much pleasure in reading in your issue of the 6th instant, Mr. Keoughran's description of the Sludai District, and am greatly obliged to him for the favorable notice he has given of the Tanah Merah Tea Estate. There are, however, one or two slight errors that I wish to correct. Of the original 60 acres opening, only 30 acres are virgin soil, yielding 400 lbs. per acre or 12,000 lbs. in all; 30 acres old labang land, yielding 300 lbs. per acre, or 9,000 lbs. in all; and 20 acres also of old labang land, but some two years younger, yielding 150 lbs. per acre or 3,000 lbs. in all. This makes a grand total of about 24,000 lbs. of tea for the year, which even at 1 shilling average would only realize some \$7,800. But it must be remembered that the 24,000 lbs. is the whole output, and in this is included about 10 per cent. or so of dust and Souchong (coarse tea), averaging about 5d. per lb. I have got at public sales in London as much as 1s. 0½d. per lb. as an average, and some of my valuations have been as high as 2s. 6d., and I expect to obtain 1s. for my new teas now going in.—J. HAMILTON HUNTER, *Manager*.—*Straits Times*.

FOREST MANAGEMENT IN GERMANY.

We hear much of the excellent system of management in German forests, and the value of the forests and forest schools as training institutes for those destined to enter the forest service of India. Some notes on the subject, therefore, from the pen of Sir Dietrich Brandis, the late Inspector-General of Forests of the Government of India, will be welcomed by all interested in forest matters. Sir Dietrich shows that modern forestry, so far from being unduly a matter of routine, treats each portion of a forest with special regard to the peculiar conditions of the locality and the requirements of the growing stock, while due attention is constantly paid to the systematic arrangements on the entire forest range. While the system is thus elastic on the one side, due care is taken to prevent it becoming confused on the other. British foresters may, it is pointed out, be startled at the mass of what they may consider needless minutiae and superfluous figures, but these details constitute the essence of methodical forestry. "The forester's success is based upon close observation of numberless minute details in the development of the trees and shrubs of which his forests are composed. The observations and measurements made by him, combined with the results obtained by the researches of others, enable him to understand the complex problems which every forest presents, and to shape his treatment in the right manner. The fundamental principles underlying the forester's profession are simple enough, but their application is difficult. This must be learnt by study and by actual experience, as in every other profession." The work before us is entitled *Notes*, and its author expressly says that it is not to be considered as a complete treatise, but is simply meant to draw attention to a few essential points which may be useful to Indian foresters. We have, in fact, an account of the forests in the Grand Duchy of Baden, including the Black Forest together with notes on forests in other portions of Germany. Of special interest are the notes on the rotation of forest and cereal crops in some districts, where the coppice belongs to certain public corporations exercising a common proprietorship over a definite tract of ground cultivating the domain on a common system and sustaining itself by the produce. The coppice is cut after seventeen to eighteen years, the bark peeled, the rods burned, the ashes spread over the cleared land, and a crop of Rye sown. The shareholders have the right to grow this Rye crop for their individual benefit, but having gathered in this crop the plot relapses into the state of undivided or common property when the coppice is allowed to grow up again. The appendix contains tables for the conversion of the methodical forestry system to the rapid and continued system still in vogue in this country, and an explanation of the more important German technical terms.—*Carleberg's Chronicle*.

THE GLASGOW EXHIBITION.

An exception may however be made in favour of tea, not only because it is remarkably well represented in this exhibition, but also on account of the growing importance of the tea industry to the British dependencies India and Ceylon. Though tea cultivation has only been carried on commercially in the island of Ceylon during the last few years, since the excessive cultivation of the cinchona has rendered that industry unremunerative, the import of Ceylon-grown tea into this country during twelve months is said to have already reached 11,300,000 lbs., whilst the import of Indian-grown tea in the last two years has increased from 65,000,000 to 83,000,000 lbs. On the other hand there has been a corresponding falling off in the importation of Chinese tea, and this, according to a recent consular statement, is causing considerable anxiety to the Peking authorities. Moreover, a report presented to these authorities by an expert does not appear to have been very reassuring. One inference drawn from this report and other papers by Her Majesty's Consul at Hankow is that both the Indian and Ceylon teas are better than the Chinese, although the Shanghai tea-tasters assert that China tea has naturally the better flavour. All admit, however, that the Indian teas are better grown and better prepared and that they are stronger and stand more watering. On the other hand it is claimed that China teas keep longer than the Indian, probably because they are freer from moisture, which favours fermentation. It is also alleged that "the removal of moisture means the removal of tannin, glucose and other elements," the retention of which in Indian tea renders it unwholesome, "a bogie" that is not likely to interfere much with its consumption. In the Ceylon court of the exhibition the growth and manufacture of tea is illustrated in all its stages, from the growing plant to the finished product in great variety, whilst it is only necessary to visit the Ceylon tea house in the adjoining grounds to ascertain the quality of the infusion it yields. A more cosmopolitan, and exceedingly creditable display of teas, is that of Pringle and Orichton, of Glasgow (No. 826), since it includes varieties from China, India, Ceylon, Java, Japan and Central Africa, as well as the so-called Paraguay tea (*Ilex paraguayensis*). A little pamphlet issued by this firm contains a mass of information as to the characteristics of the principal varieties of these teas, though we can only take from it a concluding quotation referring to the use of the term "pekoe," concerning which information has recently been asked for. "The qualities of tea in the several districts may be said generally to depend upon the age of the leaf. The finest is called orange pekoe, of which a certain portion is the partly-grown youngest leaf on the point of the shoot. Pekoe is the first and second leaves further down. Pekoe souchong is the third leaf. Souchong is the fourth leaf. Congou lower still. The shoots may be picked as low down as to produce the pekoe s'age only, but, generally, we believe the shoot is plucked at the third or fourth leaf, and then, in process of manufacture, the several kinds are 'sorted' by sieves of various sizes."—*Farmer's Journal*.

THE CHINA AND INDIAN TEA GROWERS.

The following, from the Calcutta *Englishman*, is a report of the minutes of a meeting of the committee appointed to inquire into the state of the Tea trade at Canton:

Present—Messrs. E. Descon, in the chair, K. D. Adams, E. W. Mitchell, and R. B. Allen (secretary to the meeting). Mr. F. O. Descon was unavoidably absent. The Chairman having read the notice convening the meeting invited the members of the committee to give their views on the subject under consideration. A proposed discussion then ensued, and it was finally resolved to put the following on records as being some of the points worthy of the consideration of the Chinese authorities, unless the Tea trade at Canton is to be seriously crippled, it

not altogether annihilated, by the yearly increasing competition with India.

SECTION I.—*Canton Scented Caper.*

This description of Tea, of which the bulk of the Canton export consists, competes more keenly with Indian kinds than any other class of China Teas, being especially useful for mixing purposes. The competition with India is now however growing so severe, and home prices have reached so low a range, that unless some steps are shortly taken to relieve the produce of the excessive burdens of *likin* and export duty, a time must arrive when scented Tea will cease to be an article of consumption altogether. As regards quality, the districts from which the best descriptions of leaf arrive, being the most remote from Canton, suffer most heavily from inland taxation; and this induces native merchants to admix inferior leaf grown nearer to Canton, and suffering in consequence lighter dues. One of the greatest complaints, however, that buyers have to make is in respect to the large proportion of dust found in the Teas. The dust should, if possible, not be sent to Canton from the districts at all, as the Peking dues have to be paid on it as well as on the whole leaf; and this, of course, increases the ultimate cost of the Tea. This complaint is specially to be made about leaf arriving from the Loting and Hoyune districts.

SECTION II.—*Canton Scented Orange Pekoe.*

It may almost be said that this class (both the long and short leaf descriptions) has already been beaten out of the field by the success of Indian Teas; this is amply proved by the significant fact that, during the past ten years, the export from Canton has fallen from 3,870,000 lbs. to 1,100,000 lbs. This decrease in export continues year by year; and it now seems impossible that this class of Tea can regain its lost position on the London markets.

SECTION III.—*Congous.*

Of this kind, the best Teas arrive from the Taysan districts; and, as a rule, there is a steady market for these in London. The only suggestion that might be made is that better quality would be obtained if growers were contended with fewer pickings during the year. Experience has shown that Teas plucked in the months of August and September are deficient in every quality except "make," and the picking of the leaf in these months affects the supply as well as the quality of the autumn crop, which is the best produced from the district.

SECTION IV.—*Weights.*

It is worthy of remark that Teas shipped from Canton waters invariably lose in weight on the homeward voyage, where as those shipped from Foochow and the northern ports always show a distinct gain. The remedy of this is in the hands of the Imperial Maritime Customs, for native packers are prepared to allow an extra $\frac{1}{2}$ lb. per box, provided no export duty is charged on it—a concession which the Imperial Maritime Customs will not grant.

SECTION V.—*General.*

The steady fall in exchange during late years has been of material assistance to the China grower, for it has enabled Tea shippers to lay down their purchases in London at lower sterling prices year by year, while paying almost the same tael prices to the Chinese as formerly. The native grower must be looked to for any improvement in manufacture or production; and as long as he feels no necessity for such improvement, it need not be expected. The members of the committee have read with much interest the correspondence which has already been published by the Shanghai and Foochow Chambers of Commerce relating to the decline of the China Tea trade, and they heartily concur in the opinions expressed by these bodies, and consider that the only real remedy for preventing the total extinction of the trade is the abolition of all *likin* and export duties, so that the China article may be on the same footing as the Indian, Ceylon and Java, all of which are free from tax.—*Produce Markets' Review.*

THE DEPRECIATION OF CHINA TEAS.

The rapidity with which the taste for Indian and Ceylon Teas has spread in England is making itself seriously felt in the older Tea growing country of China. The British Consul at Hankow, referring to this subject, says:—Comparing the season 1880-1881 with that of 1886-1887, we find that the decrease in the exportation of China Teas was 23,800,000 lb., and the exportations of 1887-1888 was 20,000,000 lb. less even than this. The cause is evident; it is the increased production of better Tea in other parts of the world, especially in British India, Ceylon, and Java.

The falling off in the export of China Tea is a most serious loss of profit to the native producer and merchant, and a loss of revenue to the Chinese Government. The authorities in Peking have felt the matter to be so grave, that the Commissioners of Customs at Hankow and at the other Tea exporting ports, have been directed to make enquiries in order to find out the causes of this decline, and to suggest a remedy. As a result of these enquiries the following conclusions have been arrived at:—That Indian and Ceylon Teas are better than Chinese, although the Shanghai Tea tasters assert that China Tea has naturally the better flavour. All admit that the Indian Teas are better grown and better prepared; that they are stronger and stand more watering. On the other hand, the balance of evidence is in favour of the China Teas keeping longer than the Indian, probably because they have had more moisture extracted, the absence of which prevents fermentation. It is said, too, that the removal of moisture means the removal of tannin, glucose, and other elements which make Tea unwholesome, whence it follows that the drinking of Indian Tea, in which these hurtful substances exist, is more deleterious than the use of China Teas from which they have been eliminated.

In India and Ceylon the tea plants are grown with an amount of care and attention which would strike a Chinese Tea grower as superfluous, if not ridiculous. A soil is selected at least 3 feet in depth, so that the tap-root of the tea plant may suck moisture from the subsoil in seasons of drought. The plants are grown in rows, so that the bushes may touch each other at the sides, while room is left at the back and front for the pickers to pass. Each bush is allowed to grow to a maximum height of 5 feet. Fertilising and pruning are carefully attended to. The latter is done with such thoroughness that as many as twelve and sixteen pickings can be got from a single bush in a year, and thus an acre of ground is made to produce the largest obtainable crop. It is said that an acre of Indian tea garden will produce 600 lb. of tea annually. The leaves are picked before they are overgrown, and are bruised and rolled into balls with the hand that fermentation may take place. Then the balls are broken up, and the first firing is done—if possible, on the very day that the leaves have been picked, in order to fix all the properties essential for strong and pungent tea. The rest of the preparation is all done by machinery and great care is taken to have good leads and packages.

In China there is an indifference to the selection of proper soil, so that in seasons of drought there is a deficiency of sap. Old tea bushes are rarely replaced. Manuring, removal of under-growth, and pruning, are all done in a happy-go-lucky fashion, with no idea that system and method are all essential if the growers wish to get as much tea off an acre as is produced in India and Ceylon.

There is the same want of care and of system in the manipulation of the tea leaf in China as there is in the growth of the plant. Every operation is done by hand only. Instead of bruising the leaves by rolling, the Chinese half dry them in the sun, and then place them in bags, which are trodden until a greenish viscid fluid exudes, which may contain some of the best elements of the tea leaf. Days may elapse between the time of picking and of fermenting the leaf. It often happens, too, that the grower instead of picking the leaves when they are fresh and in perfection, will deliberately wait for them to grow larger, in order that their weight may be increased. It is stated that the late

picking of 1887 made the crop 20 per cent. worse than it need have been. Lastly, in China there is not the same care in packing that there is in India. The remedies proposed for improving this unfortunate state of things in the Hankow Tea trade are threefold.—1st, the reduction of supply; and 2nd, the adoption of a better system of cultivation and preparation; and 3rd, the abolition or reduction of taxation.

Another remedy it is said has also been suggested, namely, to drive Indian Tea out of the market by sending a lecturer through England to preach a crusade against it, and to proclaim its unwholesomeness and the danger arising from drinking it.

Whatever might be the result of a better system of cultivation and preparation, the last proposition would probably hasten its decline, by advertising, and consequently increasing the sale of, Indian tea.—*Gardener's Chronicle*.

TEA NOTES.

The dried leaves of the *Saxifraga crassifolia* are used in Siberia and other parts of upper Asia as a substitute for tea. They are chiefly gathered in the valley of the Tsbarysh on a mountain, which, on that account, is called by the Russians Tsbarynaya Sopka, the "Tea-mountain." The leathery, spongy leaves of this plant fall off in the fourth year, when those only are gathered which are quite black. They require no other preparation to be used. The infusion is reddish and of an astringent taste, similar to that of tea, but the aromatic flavour is wanting.—*Penny Cyclopaedia*, Article "Altai Mountains," 1832.

HYDRUNGA THUNBERGII, Siebold, Japan.—The leaves of this shrub give a peculiar tea, there called the "Tea of Heaven."

ANDROPOGON CITRATUS, *Candolle*.—The Lemon Grass of India. It yields an essential oil for perfumery; besides, it is occasionally used for tea. This applies as well to *Andropogon Nardus*, L., and some allied grasses.

ALEX CASSINE, *Lim*, Southern States of North America.—A Tea bush to which remarkable medicinal properties are ascribed.

ALEX PARAGUENSIS, *St. Hilaire*, Uruguay, Paraguay, and Southern Brazil. The *Maté*. This holy holly, which attains the size of a small tree, is inserted in this list rather as a stimulating medicinal plant than as a substitute for the ordinary Tea Plant, although in its native country it is very extensively used for this purpose. From the province of Parana alone there were exported more than 35 million pounds in 1871, besides 9 million pounds used for home consumption; while in Rio Grande de Sul the local provincial consumption is nearly four times as much, not counting large quantities consumed by the aboriginal race. It is cheaper than Coffee or Tea (about 5d. per lb.), and an individual there uses about 1lb. per week. It has a pleasant aroma and can be taken with milk and sugar. It is the favourite beverage in large portions of South America (Dr. Mercedes Soares). The leaves destined for the *Maté* are slightly roasted. *I. Dahoon* and *I. Dipyrena* are used for the same purpose, and probably other hollies may be found equally good. Chemical principles: Caffein, quina acid, and a peculiar tannic acid, which latter can be converted into viridin acid.

MYRTUS ACUMINATA, *F. von Mueller*, Queensland.—The fragrant leaves of this and of *M. Foveolata* seem used for flavoring tea, according to Mr. P. O'Shaney.

CAMELLIA THEA, *Link.* (Thea *Chinensis*, *Link.*)—The tea shrub of South Eastern Asia, said to be indigenous also to some localities of Japan,—for instance, Suway. This evergreen and ornamental bush has proved quite hardy in the lowlands of Melbourne, where in exposed positions it endures without any attention our night frosts as well as the free access of searing, gale winds. But, it is in humid valleys, with rich alluvial soil and access to springs for irrigation, where only the most productive tea-fields can be formed. The plant comes into plentiful bearing of its product as early as the 5th and earlier than the Olive. Its culture is surrounded with no difficulties, and it is singularly free from diseases, if planted in

proper localities. Pruning is effected in the cool season, in order to obtain a large quantity of small tender leaves from young branches. Both the Chinese and Assam tea are produced by varieties of one single species, the tea-shrub being indigenous in the forest country of Assam. Declivities are best adapted and usually chosen for tea culture, particularly for Congou, Pekoe, and Souchong, while Bohea is often grown in flat countries. In Japan tea cultivation extends to 39° north latitude, where the thermometer occasionally sinks to 16° F. (Simmons). For many full details Fortune's work, "The Tea Districts of China" might be consulted. The very troublesome Tea-bug of Asia is *Helopeltis theivora*. Fumigation and the application of birdlime are among the remedies to cope with this insect. The third volume of the Journal of the Agricultural and Horticultural Society of India is mainly occupied by Lt.-Col. Ed. Money's and Mr. Watson's elaborate essays on the Cultivation and Manufacture of Tea in India. For full advice on the culture and preparation on tea, consult the writer's printed lecture, delivered in 1875 at the Farmer's Club of Ballarat.

The Tea of commerce consists of the young leaves, heated, curled, and sweated. The process of preparing the leaves can be effected by steam machinery. A machine of particular construction has been suggested recently by Mr. Joachim according to requirements explained by the writer. In 1866 three machines for dressing tea have been patented in England, one by Messrs. Campbell and Burgess, one by Mr. Thomson, and one by Mr. Tayser. To give an idea of the quantity of tea which is consumed at the present time, it may be stated that, from June to September 1871, 11,000,000 lb. of tea were shipped from China alone to Australia, and that the produce of tea in India from July to June 1872 has been 18,500,000 lb. India sent only a first small sample of tea in 1840 to the European market, but exported in 1877 to England 40,000,000 lb.—that is as much as the whole English exportation thirty years ago (Burrell). Seeds of the tea-bush are now in many parts of Australia locally to be gathered from plants distributed by the writer, and for years to come the cultivation of the tea-bush, merely to secure local supplies of fresh seeds, ready to germinate, will in all likelihood prove highly lucrative. Tea contains an alkaloid, caffeine, a peculiar essential oil, and Bohea acid, along with other substances.

GLASGOW AND BRUSSELS EXHIBITION : CEYLON TEA FOR AMERICA.

Ceylon Court, International Exhibition,

Glasgow, 31st August 1888.

The Secretary, Planters' Association, Kandy.

Dear Sir,—I have to thank you for your letter received last week, containing draft of a Brussels Exhibition £100.

You will have since received Mr. Haldane's report on his visit to Brussels, and you will learn that in spite of the magnificent buildings, the tempting surroundings and the splendid promise, the Exhibition in Brussels is as far as attracting numbers goes a comparative failure.

Exhibitions are always lotteries: Glasgow has succeeded beyond the expectation of the most sanguine. Brussels has disappointed everybody, but the Planters' Association need not be discouraged in consequence, and I believe though the Exhibition will only be visited by perhaps one million instead of the estimated five and the number of cups of tea drunk will be proportionately less than we expected, the advertisement will be a good one and will well repay the Planters' Association. One of the native servants, Simon Peter was reported to be ill, and, as we had also unsatisfactory reports of his general conduct, I ordered him to be sent here, the directors of the S. S. "Lady Gordon" having kindly consented to convey him to Ceylon. I had him examined by a doctor on arrival here, and, as the doctor thought him too ill to travel, I was obliged to place him in the infirmary. I visited him there yesterday and find he is improving, and I shall send him back by the first opportunity.

Captain Whitley of S. S. "Lady Gordon" kindly undertook to convey to you a parcel containing a few of our handbooks. The catalogue attached to this is unfortunately very imperfect, and I am sorry that many names of exhibitors have been left out. It was impossible for me to compile a handbook myself, and I felt that it could not be in better hands than Mr. Capper's, but I intended also that the printers should be in London. Unfortunately our Exhibition rule made it necessary to employ Messrs. Constable of Edinburgh, who of course had a great press of Exhibition work on, and the difficulties were much increased by the tardy arrival of exhibits. That the little work as a means of drawing attention to Ceylon is a success we have constant and abundant proof, but I feel that an apology is due to those who have come forward to help us with exhibits and whose assistance is not publicly recognised in the catalogue. While in this connection may I again beg that all who have sent us exhibits as loans will as soon as possible send us full instructions as to their disposal at the end of the Exhibition, as our labour and expense will be much lessened thereby. I hope also to hear from you that we may dispose of and credit the P. A. with the proceeds of the show cases. They are very unwieldy, expensive to store or move about.

On Friday last week we had the honor of a visit from the Queen and several members of the royal family. Her Majesty looked closely at many things, and frequently stopped to examine things. Mr. Hayward's collection of rough and polished gems, the Dagoba with its surroundings of plants and stuffed animals, Messrs. Somes & Co.'s case of exhibits from Pallekelle and Hoolankanda, the tea cases, the cacao and spice cases, Miss Gordon Cumming's pictures and the case containing specimens of gold and silver native workmanship all specially attracted the Queen's attention. Her Majesty also paid special attention to the diagram prepared by Messrs. Gow, Wilson & Stanton, showing the growth of the Ceylon tea enterprise. We had been fortunate in obtaining the loan from Mr. Bullen, the Director of the Botanic Gardens, of several Ceylon plants, palms, cinchona, anatto, cinnamon, castor oil and others which set off the Court very much, and made it very interesting. Mr. Bullen also helped us much in arranging our Court for the royal visit, and I promised him that as a slight token of our gratitude I would procure him a packet of seeds from Ceylon, so if you would kindly take this in hand and place the matter in Dr. Trimen's hands, I should esteem it a personal favor. Glasgow Exhibition continues to attract beyond all expectations and our sales of tea in cup keep steadily up to about an average of 6,000 per week.

I am quite sure the P. A. is on the right track in doing something to stimulate the introduction of Ceylon tea into America; my experience and that of many others who have tried it is that an initial loss has to be faced and that we are unwilling or unable to face, now that Messrs. Ellwood & May have declined the liberal offer made to them, I have no hesitation in saying that I can get agents who will gladly accept the same terms, they will not however go in for wholesale distribution of samples, but if they receive gratuitously 1,000 lb. of tea for every 2,000 lb. they purchase and are thus enabled to buy 33 per cent below market rates they will be able to face the loss generally inseparable from making markets.

Mr. J. McCombie Murray, who is having a very hard struggle in Philadelphia, would, I believe, gladly avail himself of this assistance, and comply with terms, and if we or any others in correspondence with him in London were empowered by the P. A. to hand him 1,000 lb. of tea gratuitously for every 2,000 lb. he purchased and shipped to America up to the amount of say 6,000 lb., I believe good business might result. Such tea must, however, be purchased and if need be mixed in London if the venture is to be a success. There is much prejudice to contend against in opening up new markets, and though a second shipment may be better than the former one if the character is not similar, dissatisfaction ensues. We had our Court photographed after the Queen's visit, and I hope to send you copies soon.—Faithfully yours, (Signed) J. L. SHAND.

COTTON-GROWING WITH TEA IN CEYLON.

A very interesting experiment has been begun by Mr. James Blackett on one, or more, of his Dolosbage properties. He has planted or rather sown a considerable area of cotton seed amongst his tea. The fields chiefly chosen are on "Jak-tree Hill" at the back of Vellekande, not far from Gampola, on undulating indeed rather side-long land. Of this old coffee plantation Mr. Blackett has cleared 70 acres, planting it with tea in the usual way and then, buying one cwt. of Egyptian cotton seed for R8, to try an experiment, he found he had enough seed to go over 100 acres! He accordingly had the soil forked up at intervals, in place of holing, throughout the 70 acres as well as some 30 acres on another property and then dibbled the seed in, two seeds to a hole, at about the same number of cotton plants to an acre as there will be tea. The whole expense of this cotton experiment so far, does not exceed R2 per acre! Of course "the proof of the pudding is in the eating," and there are several contingencies to be faced which may bring about a loss rather than profit. But, meantime, Mr. Blackett has found the cotton seed coming up and sprouting within three days of being put in the soil, and he anticipates that the shrub will grow so quickly as to save him very soon the expense of weeding his tea land, while he thinks the shade will do good rather than harm. On the other hand, cotton is known to be an exhausting crop, but Mr. Blackett intends after harvesting to root out and reduce the bushes to ashes, returning the same to the soil. As regards the crop much will depend on the weather, and on the face of it, we might suppose the Dolosbage or Gampola district to be far too wet to be a successful cotton-growing district. But Mr. Blackett has chosen his season very judiciously, for by the time the harvest arrives in March-April next, the dry season will be fully on in his district. He will have to provide a gin, or gins, to clean the cotton before sending it to Colombo. But we need not anticipate these and other contingencies. Mr. Blackett has now secured a small packet of Fiji, the best South Sea Islands seed, to try a further experiment. It is reported that Sir Arthur Gordon has interested himself in arranging that about a ton of the best Fiji seed be got for Ceylon. We may expect to see the example of Mr. Blackett freely followed by planters in several of our lowcountry districts.

TOBACCO IN BORNEO.

The Prospectus has been issued of the London Borneo Tobacco Company (Limited), with a capital of £120,000, in 11,999 ordinary £10 shares and ten founder's shares of £1. Of the ordinary shares 4,000 have already been applied for and will be allotted in full at par, and 4,000 are offered for public subscription. The remaining 3,999 ordinary shares will be allotted to the vendor in payment for the property, but will not rank for dividend in any year until 10 per cent. dividend has been paid on the 8,000 shares allotted to the public, and 10 per cent. of the net profits has been set apart to form a reserve fund until the same amounts to £40,000. The vendor's 4,000 shares will then rank *Pari passu* with the 8,000 shares in each year as regards any surplus net profits, and after 100 per cent. has been paid in dividends on the 8,000 shares allotted to the public, will have equal rights in every respect with those shares. The ten founder's shares will be allotted to the vendor for cash; they will be entitled to no benefit until £100 per cent. has been paid in dividends on the 8,000 ordinary shares issued to the public, but thereafter they will be entitled to one-fourth of the net profits in each year, provided dividends of 10 per cent. are paid on the whole of the ordinary shares and a provision made for reserve

fund as above. The company has been formed for the purpose of acquiring a grant of land purchased by Count Charles de Geloës d'Elzloo from the British North Borneo Company, containing an area of 26,000 acres, situated in Marudu Bay, British North Borneo. The tenure is for 999 years, free of quit rent, subject to an export duty of one cent of a dollar per pound avoirdupois on the tobacco grown on the land, to commence to be paid after January 1st, 1892, which duty the British North Borneo Company have guaranteed will not be increased for twenty years thereafter, the object of the company being the cultivation of tobacco for export to European, American, and other markets. Count Geloës, who has already achieved considerable success in tobacco growing in Borneo, has consented to be the managing director in Borneo for the period of five years. We may remark that, previous to the issue of the prospectus to the public, the whole of the capital was virtually subscribed. Not only this, but the company was formed in an incredibly short space of time. It may also be mentioned that the expenses of starting the company are on the lowest scale, and that no promotion money has been, nor will be, paid; the concession for the land being paid for in shares to the vendor. It is evident that tobacco growing in Borneo is coming into considerable favour.—*L. & C. Express.*

FIIJI TEA.

Several weeks ago the first commercial consignment of tea from the colony of Fiji was received in Mincing Lane, and was pronounced by experts to be good, the infusion having a good body and fair aroma. We were fortunate in receiving a small sample of this importation. To India we may confidently look for our future supplies of "the cup that cheers," and, if China refuses to receive our Indian opium, it may be some consolation to Anglo-Indians to know that we have ceased to be enamoured of her tea. To Ceylon also we may with confidence look for future supplies. Ceylon tea is in some respects better than the Indian kind, resembling rather a blend of Indian and China teas, and for this reason mainly it has grown enormously in popular favour during the past few years, so much so, indeed, that agriculturists in the island may expect ere long to get over the disasters which their excessive production of cinchona has brought upon them. That extremely interesting country, Johore, which recently attached itself to the rule of our Queen, is trying what it can do in the cultivation of tea, and for many years Natal has used tea of her own growing, while Jamaica is also experimenting with some hope of success. For various reasons, the chief being the proximity of Fiji to Australasia, we regard the cultivation of tea in that island as being almost of equal importance to its cultivation in India. [Absurd.—Ed.] All the Australian colonies, including New Zealand and Tasmania, consume amongst them over 22,000,000 lb. of tea annually, or about 7 lb. per head of population, while in Great Britain we only consume 5 lb. per head of population; this, however, being more than the whole continent of Europe put together. Australasia, it is apparent, is the natural outlet for Fiji tea, and when that satisfied Fiji may tap the United States, which is exclusively supplied by China and Japan at present. Fiji is better situated to compete with these countries than either in Ceylon or India. The industry is still young in the colony, having been started in 1880; but there are several thousands of acres planted with it, and the plant seems to thrive well. It is somewhat dearer than it is in Ceylon, and the quality of the tea is able to stand this, and there is a hope that as the colony develops Fiji tea may get it in their own interest, and so lessen the expense under this head. The samples of Fiji tea which were shown at the Colonial and Indian Exhibition were mostly of excellent quality, and the reputation which has been received in London recently certainly speaks in so far as the public is concerned. Chemical analysis has not yet been able to determine

* Fiji cannot possibly compete with India or Ceylon in respect of favour supply both for cheapness and reliability.—*F.*

the market value of tea, nevertheless we believe that some fact which an analysis of the sample submitted to us has revealed are not without interest. The amount of moisture contained in it was found to be 6.4 per cent.—a figure which compares well with the 7.10 to 12.66 per cent. found in the best Russian teas, which are typical of the China produce. Recently Messrs. Paul and Cownley examined twenty-eight sample of Ceylon tea, and found the moisture to vary from 3.6 to 7.56 per cent., with 2.4 to 4.66 per cent. of theine. The samples of Russian tea referred to contained from 1.36 to 3.09 per cent. of alkaloid, and our sample of Fiji tea yielded us 2.35 per cent. of beautiful theine. This alkaloid has long been regarded as the only alkaloidal constituent of tea, if we may except paraxanthine theobromine, but a recent research by Kossel has revealed the existence of a second base, to which he gives the name "theophylline," and regards it as an isomer of theobromine and paraxanthine. The crystalline body was found to have the formula $C_7H_9N_4O_2 \cdot H_2O$, the molecule of water being expelled on exposure to a temperature of $110^\circ C$. The solubility of the new base in alcohol and water is similar to that of theobromine, and the form of the crystals accords with the form of paraxanthine. Theophylline melts at $264^\circ C$, paraxanthine at $280^\circ C$, and theobromine sublimates at $290^\circ C$. without melting. Kossel regards the new base as a xanthine derivative. Messrs. Paul and Cownley have announced since this discovery was made known that some months ago they obtained distinct evidence of the presence in tea of an alkaloid distinct from theine.—*Chemist and Druggist*, July 28th.

TEA IN VIENNA AND AUSTRALIA

GENERALLY.

With reference to the enquiry of "A Planter" following on the letter of "A Well-Wisher," we have to say that evidently in Austria, as in many parts of France, there is no taste for tea-drinking. The public taste has to be educated and that is a slow process at the best. In the centre of France even in big towns, when enquiring for tea, we were referred to the "Pharmacy" stores. Tea was regarded as a medicine! The case is different now in Paris among the better classes especially, and at this moment we know no better opening for an energetic business man and good linguist than in the establishment of tea stores or agencies, or even restaurants, in Paris. The same is, doubtless, true of Vienna, for here is the corroborative information very kindly placed at our disposal by the Agent of the Austro-Hungarian Lloyd's, on our referring "Planter's" letter to him. Mr. Marinitsch writes as follows:—Austro-Hungarian Lloyd's Steam Navigation Company, Colombo Agency, 21st Sept. 1888.

Dear Sir,—Replying to your note just to hand, I am unable to quote you the exact reason why tea is so highly priced in Vienna. I know that duty amounts to 3s stg. (E. money) per kilogramme = 2 1-5th lb. Some time last year I sent a consignment to my Trieste friends and it did not come off successfully. My friends wrote me some time ago in reply to my urgent appeals to push Ceylon tea, as follows:—"Regarding your remarks about tea, we have only to state that the consumption of tea in the Southern provinces of our Empire is very small indeed; in Vienna, Galicia, Bohemia, the better class of people drink tea, but not in like quantities as England or Russia, or even Holland and Germany. Only Ceylon tea is wanted, and the quality mostly consumed is as follows, costing at 23d per kilo equal to about 11s per cwt."

I trust the above information may be useful to your planting friends.—I am, dear Sir, your faithful servant,

G. A. MARINITSCH

Another mercantile authority on Continental matters remarks:—

There is no consumption of tea to speak of in Austria, nor I should say any likelihood of a demand for our now staple planting up in a hurry. The price of 8s 6d sterling per pound, mentioned in your corre-

spendent's letter, is doubtless a mistake, unless it refers to a fancy quality. With all that, Ceylon ought to feel some gratitude for the very high prices Austria used to pay for Ceylon coffee as long as there was such an article.

COCONUT PLANTING IN THE LOW-COUNTRY OF CEYLON:

A TERRIBLE DROUGHT; PEPPER; COCONUT CULTIVATION. HAPITIGAM KORALE, Sept. 1888.

On the 27th 28th, and 29th August we had showers aggregating about two inches. This revived things a little, but since then bright sun and a gale of dry wind, for six hours daily, has licked up every atom of the moisture, and everything that habitually suffers from drought, is suffering more than before. The coconut trees of all ages have more unseasonably withered leaves than I have ever seen in the S.-W. monsoon. My few remaining Liberian coffee trees are on their last legs; bread fruit trees are well nigh denuded of leaves, the cush-cush beds have withered down to the ground in many cases and vegetables are perishing wholesale. The wells are running dry: we are put to much trouble in finding water for the cattle and they are greedily eating what a few weeks ago they would have scorned. Altogether we are having a rather bad time.

As the question of growing Pepper on protruding boulders has been raised, I may as well state my experience on that point. I found that the vine will not attach itself to a rock that departs more than about 10° from the perpendicular. That it thrives best on the north side, not so well on east and west, and on the south not at all. That it will spread over flat or slightly sloping rock but will not attach itself. That in a favourable season it will yield a good crop but cannot be depended on for a succession.

I have already communicated to you my plan of cultivating Pepper as a low bush. It is my intention to try the next wet season an experimental patch of 300 plants so as to place the discovery beyond question, and if the first patch should promise success, to extend it the following year to ten acres.

When in my last I mentioned 60 nuts as the average per tree per annum, it was not as an estimate for the district, but the ascertained yield of a single estate. This record is, however, beaten into chips by a Katukenda property said to average 97, or within 3 of the number I have always stood up for as the result of skilful cultivation. Dr. Shortt holds 100 a very safe estimate for the Malabar Coast, whereas Ceylon cannot safely be estimated at over 20, if we include the sea shore and the village topes—all the difference lies in an annual expenditure of 15 cents, the value of seven coconuts annually in labour and manure. Taking the general run of Ceylon coconut proprietors, the most advanced notion of cultivation is a clean surface of pasture grass kept up at a cost of 3 cents per tree per annum.

COFFEE AND CARDAMOMS.

NOTES FROM HAPUTALE.

18th Sept.—There is no mistake now about the setting in of the N.-E. monsoon, for up here we have been having it wet and stormy for the last 24 hours; thick mists and occasional squalls from all points of the compass. This change of weather is very appreciable after the long spell of drought we experienced for nearly three months, which, if it had continued longer, would have done serious damage to all cultivation. Coffee blossoms have been retarded and only on scattered fields and wherever the bushes were in good heart has there been any blossom to speak of, this rain has just come in time to save and bring out a spike that has been hanging on the trees for some time. It is too early yet to conjecture what the coming coffee crops will be like; on some places the autumn crop now on the trees is pretty fair and generally speaking estates are in good condition for a fair crop next year, notwithstanding the long neglect and want of proper cultivation and systematic manuring and nursing which poor old king

coffee has undergone. I am of opinion, even with all diseases and calamities which coffee flesh is heir to, that this product will give the best returns and profits to those who stick to it, and by proper cultivation do justice to it—leaf disease and green bug to the contrary. Tea is first favourite at present, and everyone with a few acres in bearing "factory mad" and inventing new machines, otherwise building "castles in the air." Expensive buildings and costly machinery were some of the items that added the "last straw" to the back of the coffee enterprise, and I very much fear, but that gigantic factories and costly machines will be the rocks on which the tea enterprise will split and fortunes sink. Cardamoms in shade have benefited by the long drought, as the sun penetrated to the very roots and has brought out excellent racemes of blossom and the coming crop should be a good one: pity the market for this product is so ridiculously low, the prices realized barely pay for gathering and curing. Tobacco, cotton and pepper are the new "colts" entered for the next "Ceylon sports and races"; ever something new, planters seem to delight going "out of the frying-pan into the fire," and properly stewing in their own juice.—J. A.

THE TOON TREE—WHITE AND RED VARIETY.

Mr. Deane of Kintyre, in answer to our inquiry, reports:—"The Toonas I referred to are the *white variety*." We learn through Mr. Cross Buchanan that Mr. James Taylor's unfortunate experience was also of the white toonus. So that, it is clear there is nothing said against the hardier red kind, the planting of which we urge on all tea planters above a medium altitude.

PLANTERS' TROUBLES IN BURMA.

Tavoy, 10th August, 1888.

Dear Sir,—Some years ago I saw an advertisement by the Burman Government that they would grant land, and would give every facility to planters that would be willing to open up land in the district of the Tavoy hills. This induced me to go to see the land and judge for myself whether the soil was really fit for tea, coffee, or cinchona. Of course, I thought that I could reach the spot by a road, but am sorry to say that there was only a road of about 20 miles from Tavoy; the remainder 30 miles I had to walk, swim, and manage the best way I could. I got up to Niadong, where, to my surprise, no shelter was to be found, but must confess the land I saw was good. But what is the use of land when you have no road to get provisions for self and coolies within 50 miles from any village, let alone the cost of transport? I was, however, repaid for my troublesome and expensive journey, when I arrived on my way back at the Model Duke Estate, where I saw coffee, tea, fruit trees of all descriptions thriving as well as I have seen in India or Ceylon (if not better), and in my opinion the land was not as good as in Niadong.

The Government ought to be extremely thankful to Mr. Watson for having planted up an experimental garden at his own expense for the good of the Government, as I hear he had but little assistance from the Government. But, after all, what is the use of all when the Government stand in their own way by not constructing roads to induce pioneers to invest their money in the Tavoy hills? Unless roads were constructed to enable them to get to the land conveniently, and the land laws made a little more favourable, I have no doubt, that many planters from Java, India, and Ceylon, who would only be too glad to avail themselves of the land so offered, would refuse to come.

Trusting, Dear Mr. Editor, you will give this room in your valuable paper, so as to prevent others from a troublesome and expensive journey.—A PLANTER OF A QUARTER CENTURY.—*Rangoon Times*.

Correspondence.

To the Editor.

CACAO AND ITS ENEMIES:

Kandy, 4th Sept. 1888.

DEAR SIR,—In your issue of August 29th appears a letter signed "Pottinger," accusing your correspondent, "Peppercorn," of want of experience upon the subject of cacao, thus inferentially denying the truth of his statements *re* that product. The letter which seems to have aroused "Pottinger" 's ire mentions that a new pest is attacking the young cacao pods by biting round the stalks and so causing the pods to wither and fall. This insect whose ravages "Peppercorn" correctly describes is the girder (*Oncideres cingulatus*). Professor Haldeman in the *Pennsylvania Farm Journal* says:—"This insect was first described by Say in the *Journal of the Academy of Natural Sciences* in 1825, and its habits were discovered by us and published in our 'Materials towards a History of the Coleoptera Longicornia of the United States, 1837.' In our walks through the forest our attention was frequently drawn to the branches and main shoots of young hickory trees, which were girdled with a deep notch in such a manner as to induce an observer to believe that the object in view was to kill the branch beyond the notch, and, extraordinary as it may appear, this is actually the fact, and the operator is an insect whose instinct was implanted by the Almighty power who created it, and under such circumstances that it could never have been acquired as a habit. The effect of girdling is unknown to the insect, whose life is too short to foresee the necessities of its progeny during the succeeding season."

Duncan, the well-known geologist and naturalist, writing of the girdling propensities of the *Oncideres*, says:—"Now what is the reason that the beetle should cut away the branch? If it is that which is usually considered to be true by naturalists, it is a most wonderful instance of superior instinct. It is supposed that the branch is cut off in order to prevent an unusual supply of sap flowing into it, or with a view of diminishing the amount of sap circulating generally in the branch. Were the incision not made through the bark and the flow of the sap not checked the larvæ would suffer from too great abundance of liquid in their immediate neighbourhood; and the diminution of the sap is necessary for the perfection of the metamorphoses."

I have carefully examined several pods thus treated by this insect, but have not been able to find larvæ in any of them. Suffice it to say that it is one more enemy of the cacao, and, from the amount of pods recently destroyed here, an enemy to be feared. "Pottinger" says:—"Let anyone visit at this present any properly-constituted cacao estate, and see the enormous crop, remembering also the fearful droughts which have been undergone." I have just returned from a trip in other cacao districts and I find that, like here, they have had any amount of blossom, but that very little has set and that the trees look so sickly and yellow that it is an open question how much of that already set will come to maturity, and that there is every likelihood of crops being exceedingly short this year.

As for the concluding paragraph of "Pottinger" 's letter, that there is absolutely nothing in Ceylon (and very few things elsewhere) worthy even to touch the latchet of the shoes of cacao, he can hardly expect that to be taken seriously. The fact of the case appears to be as follows:—From 1881 the cacao trees now flourish and produce from trees already in bearing 5 cwt. per acre seemed a fair and moderate estimate of crop to be expected in the

6th year. In 1884 however a disease attacked the cacao tree, several estates went out very quickly and the surviving estates assumed a very shucky appearance. This was attributed by some to the drought of that year, but the fact remains that the trees have never recovered their earlier look, nor have they given anything approaching the 5 cwt. we so confidently expected. Let any one look at the exports of cacao for the last four years, and he will see that 2 cwt. per acre is not realized.

My opinion is that, grown in good soil, well shaded and sheltered, from 1½ to 2½ cwt. per acre may be expected from cacao in the 7th year, which would certainly leave a margin of profit, but nothing to warrant "Pottinger" 's extravagant eulogy.—I am, sir, yours truly,
CACAO PLANTER.

P. S.—I enclose my card.

CINCHONA CULTIVATION IN DIMBULA.

Henfold, Lindula, 12th Sept. 1888.

DEAR SIR,—In sending you figures I did not pretend to have had my cinchona trees counted, and I know that many in this district did what I did, viz., sent a statement of what I *thought* I had, and the wish I fear was father to the thought. I am now sure that I greatly overestimated, and yet Henfold is a show cinchona estate. Again how many deaths have occurred since the return was sent to you? And no planting to speak of has been done for years, and self-sown plants come to nothing! And how many estates since then have been almost cleared of cinchona, and some of those places that had the most? Kindly inform me the date of the last return made to you, and oblige, yours truly,
GEO. BECK.

P.S.—I fear from what Mr. Mackwood tells me,—he has just left me,—that it is a borer that attacks my Toona trees. They are not the hard red Toona. We have them also, and they are not attacked.

[Our cinchona returns were generally dated this year from March onwards. We are, however, about to take steps to have certain districts checked, and we trust planters will do all they can to aid us.—It is interesting to learn that in Mr. Beck's case the insects have discriminated and confined their attention to the white toons. Those we are cultivating and recommending are the red variety. Dr. Trimen's communication shows that even these can be attacked, but that the attacks are of little consequence, as the boring is confined to the tender branchlets, the trunk and large branches not being touched. We take it for granted that even the white toons have the borers only on the tender shoots? So long as that is the case, the effects will only alter the character of the foliage, and Dr. Trimen does not believe the insects will attack our cultivated plants.—Ed.]

BORERS IN *CNDRELA* TOONA.

Kintyre, 15th September 1888.

SIR,—On this estate every toon tree was attacked when about 15 to 18 months old, although they were only planted here and there through the estate. The grubs grow to about 1 inch long at largest, and each tree contained from 3 to 20 of them. I coppiced every tree below the grub holes, and burnt the grubs, but in three months' time, when the coppiced trees threw out new shoots, the grubs came back at once in swarms, so I reluctantly needed out and burnt all the trees. The grubs were of a white color, with red hair on them when they grew to a large size, the smaller ones having little if any hair observable.

A curious thing was that no matter how isolated the tree was the grubs found it out, and there are none (or certainly, if any, but very few) trees of this variety on neighbouring estates. H. D. DEANE.

[The question still remains, have the insects ever attacked trees growing at and over 4,800 feet? Trees growing on Abbotsford at this height and now seven or eight years old have never been affected; neither have the younger trees at higher elevations there and in Nuwara Eliya. We refer entirely to the red-foliaged variety of toon.—Er.]

MUSTARD AS MANURE FOR TEA.

(To the Editor *Indian Agriculturist*.)

August 5, 1888.

Sir,—The Secretary, Dehra Doon Tea Co., asks for information regarding Mustard and Tea, which I have much pleasure in giving, answering his questions in the order put.

1. The black variety I think the best and cheapest.
2. Eight seers per acre.
3. If sown in March, the crop would be fit to hoe in by the 21st May, and would therefore not interfere with leaf-plucking.

4. Annual sowings would have to be made. A dressing of gypsum (native sulphate of lime) powdered, and at the rate of 5 to 10 cwts per acre, with powdered saltpetre 2 cwts. per acre to be applied when the mustard crop was 2 inches high, or just after hoeing the latter in, would give a good return of leaf. Let Mr. Gibson try this on, say, five acres, and report results, as it is a question that has long puzzled planters how to increase the yield of leaf.

J. R. C.

[As neither gypsum nor saltpetre is readily obtainable in Ceylon, ground castor cake and ground bones might be used, in limited quantity of course.—Ed.]

STONE TERRACING AND MANURING FOR TEA.

Singell, near Kurseong in the Darjeeling district, is a steep and stony place, and must be amongst the oldest of places in the district. The following paragraph in the latest report may afford a hint to proprietors of similar places in Ceylon:—

CULTIVATION—The entire garden has had the deep cold weather hoeing, and since then has been kept in good cultivation both with the hoe and sickle. The pieces of cultivation we stone terraced and filled in with manure during the cold weather are looking and doing exceedingly well. This plan of terracing the steep parts of the garden is so beneficial that we hope to do a great deal more this coming cold weather. Over 6,000 maunds of manure have been carried into the garden, and a like quantity will be available this coming cold weather. The rainfall to the 30th June is much behind last year.—*Indian Planters' Gazette* Sept. 4th.

GOLD DIGGING ON THE ELK PLAINS.—A correspondent of the local "Times" says:—

"Mr. Hirsch has now moved his camp nearer Haputale, and is sinking another shaft. He is very sanguine about finding gold, although up to date nothing but disappointment has met his efforts. Yesterday Mr. Cochran reported that a sample, supposed to contain any quantity of the precious metal, contained only iron. Curiously, no gems have been found, although much of the soil removed is similar to that of the Ratnapura gem pits. Mr. Hirsch is living in a small hut, together with twenty Sinhalese villagers, and works through wet and cold in a manner that few planters would care about. Such is the thirst for gold! We wish him all luck."

The same correspondent, referring to the first pit, says:—

"The pit was not abandoned—as the *Observer*, whose reporter visited Mr. Hirsch, stated—because it fell in, but because it was not considered good enough to go with, and it only fell in after the last board was taken out and the supports removed."

We never said it was abandoned because it fell in, and our contemporary's correspondent will do well to read communications more carefully before seeking to correct them.

PRICE'S PATENT CANDLE COMPANY LIMITED.—The directors of this company state that, subject to audit and without making any deduction for the expenditure on new machinery and plant, the accounts show a profit for the half-year ended June 30th, of about £28,500. They recommend an interim dividend of 10s. per share, which will absorb £18,750.—*Chemical Trade Journal*, Aug. 11th.

MICA.—We had occasion to notice the other day the success attending the efforts of Hautefeuille and Perrey to reproduce artificially two well-known minerals of the gem family, emerald and phenakite. It is now reported that M. Doelter has been equally successful in the artificial reproduction of the chief minerals of the mica group. He has been describing his process to the Paris Academy of Sciences.—*Chemical Trade Journal*.

KURSEONG AND DARJEELING TEA COMPANY.—The latest return from the Gardens is to the 21st August. The quality of the tea from the Darjeeling and Terai Gardens has been disappointing; the former Mr. Dornay attributes to the very dry weather; at the latter the manufacture is having Mr. Dornay's attention. Prices for fine Orange and Broken Pekoes have been lower than last year, but for other qualities with point and character there is a good enquiry.—*Indian Planters' Gazette*, Sept. 4th.

TEA IN HAPUTALE.—We are assured by an experienced planter and inspector of estates with large interests on the Kandy side, that he knows nothing finer in the island than the tea at 6,300 feet,—the same elevation as Nuwara Eliya,—on Dambatenne estate, Haputale. As much as 400 lb. of tea per acre can be got at four years' old, which is a specially good return. All the upper divisions of Uva, it is evident, will do exceedingly well in tea: the medium elevations fairly well; although some doubt may be felt about the lowlying and drier places.

AVICULTURE is an industry which should be introduced for the benefit of the people of Ceylon. Can the Director of Public Instruction not take it up?—The French Minister of Agriculture has just established a practical School of "Aviculture," or school for the breeding and rearing of poultry; their fattening and artificial hatching; the management of eggs, their preservation and preparation for market, and the most advantageous breeds of poultry. The period of residence at the school is limited to three months; the fee is 350 fr. board &c., included. The school is situated at Hodan, in the Seine and Oise department, a region famous for its races of barn door poultry. Male and female pupils are alternately received every three months.

SUGAR PLANTERS in Queensland and elsewhere, it would appear, need have no fear that the new chemical products called saccharine will ever prove a formidable competitor to cane sugar. In a paper read recently before the Paris Academy of Medicine, some particulars were given of the results of experiments made with saccharine upon patients in various hospitals. Dr. Stadelmann, of Heidelberg, took observations in 11 cases where 80 grains of saccharine were given daily for two or three weeks. Nine of the patients experienced no bad effects; but in the case of the other two, nausea, loss of appetite, and pains in the stomach resulted. In three out of four cases of diabetic patients the digestion was injuriously affected after eight or ten days. A committee was recently appointed by the Paris Board of Health in order to inquire into the dietetic properties of saccharine, and the committee have expressed no opinion that saccharine should be debarred from use in articles of general consumption, as being prejudicial to public health.—*European Mail*.

THE CHINESE TEA:

ITS CULTIVATION AND MANUFACTURE.*

The consumption of tea is so universal amongst a large portion of the inhabitants of the globe, and its culture is of such importance to the vast Chinese empire, that a full exposition of the culture, preparation, and uses of this plant will be here in its right place. The plant which produces the common kinds of tea in commerce, is the *Thea chinensis*, of which there are a number of more or less constant varieties, so that several botanists have made not only two, but three, distinct species, viz., *Thea viridis*, *Thea bohea*, and *Thea stricta*. I shall afterwards return to the reasons which determined me to receive one species as furnishing the Chinese tea.

China is the native country of the tea plant: it is found there as high as the 40th degree of north latitude, as well as in the mountainous districts in the southern parts of the country, particularly on the mountains which separate China from the Birman empire. That the culture of the Chinese tea is also carried on in Ava, the Birman empire, and on the eastern borders of Thibet, Ritter has proved from accurate sources. But the tea plant has recently been found wild in Assam, and, indeed, in the territory which belongs to the English, where the mountains are not above 6,000 or 8,000 feet high; and therefore great hopes are entertained that the culture of tea on a large scale will soon be so successful there that the trade in this article will soon be snatched from China. A large quantity of ordinary tea is produced in Cochin China and in Tonquin, yet here this branch of agriculture is much neglected. Whether the plant is wild here, or whether it has been introduced, we do not yet know; the latter might almost be supposed, for the tea-plant thrives best in the sub-tropical zone, consequently it will be indigenous in it, as well as on the heights of mountains corresponding to this zone. The use of the warm infusion of the leaves of this plant, which is known by the name of tea, stretches back into the earliest times of Chinese history, and it is at present so universal throughout the empire, that the consumption of tea leaves can scarcely become greater, and if the population does not increase.

Much has already been written on the origin and on the native country of the tea, and old Chinese writings are continually brought forward as authorities. Siebold has very lately tried to disseminate the opinion that the tea has been introduced into China from Koorai, which, however, Kluproth has shown to be erroneous. He has shown that the earliest notices of the use of tea stretch back to the years from 265 to 419. In the Chinese writings which bears the title *Sahn-seane*, we find that in the middle of the fourth century a minister of the public building, Wang-mung by name, used the tea-plant, which in Chinese is called *Ming*. In the year 690 the plant was recommended by a priest to an emperor of China, who suffered much from headache, and as the illness was soon cured by using tea, the use of it was speedily adopted everywhere. *Tschia* is a synonym for the plant *mung*, and by that name the dried plant was first brought into notice by the Portuguese and Spaniards; the word *Tschia* is also common in all the northern provinces of China. Kluproth considers the word *Tschia* to be the Malay *Teh*, which is derived from the Chinese word

Tschia. The culture of Tea in China must have been very considerable as early as the 8th century, for in 763, at a taxing of the empire, a duty of 10 per cent. was laid on tea, and since that time the government has always derived a large revenue from this useful plant. At the present time the tax on tea is collected in the following manner; none of the country people are allowed to sell tea without permission; but these permits are obtained at the Custom-house of the province, and for the precise quantity which is to be sold a double receipt is issued, one of which the seller keeps, while the buyer receives the other, in order at any time to prove the legality of the sale. Tea has been known in Japan since 810, and it has been cultivated in the Corea since 828. Its culture also has been attempted in Bengal, and great success is expected from it, nay, this question has been very recently discussed by Royle, yet, as it seems, with great partiality to India. I shall subsequently attempt to show that even though the tea-plant can be grown in all the cooler parts of the tropical zone, over the whole sub-tropical, and even for within the temperate zone, to about the 40th parallel, yet there are other circumstances necessary in order to a profitable culture of the plant. The chief one is a low price of labour, which is, indeed, very low in Bengal, as well as in China; but that it is in India only one-fourth or one-half as high as in China, which Reeves has asserted in Royle's work, may well be doubted; if it were so, then Bengal would soon furnish cheaper tea than China. The day's wage may indeed be eightpence at Canton, where Mr. Reeves lived, but in the interior of China it is only a fourth of this sum. Besides, in these countries, tea has been planted in Ceylon and Java, whence some thousands of chests are annually exported. The tea of Java has lately reached the market of Amsterdam, and excited much attention there, for above 1,400,000 lb. have already been obtained, so that the Dutch will probably within twenty years draw the whole quantity of tea they require from Java. According to Marsden few tea bushes were cultivated in Sumatra in the last century. The tea has also been planted at the Cape of Good Hope, in St. Helena, and at Rio Janeiro, where there are still large plantations of it in the Botanic Garden, but these are in a miserable condition. Plantations of tea are formed by sowing the seeds, which are set more or less regularly. In the first year the middle shoot is stopped, that it may not grow tall and slender, but may become bushy, and be covered with a greater quantity of leaves. The crop of leaves begins in the fourth or fifth year. I have visited such tea plantations, and found them in hilly situations which is said to be the case throughout the country. The plants in these plantations were in general only two and a half or three feet high, and they stood about three feet apart; a few branches only shot beyond the rest and reached a height of five feet. I have found women sitting beside these bushes and plucking off the leaves by hand in the ordinary way. From the different statements respecting the time of gathering them, it seems to vary much in different parts of Chinese and Japanese empires; however, the principal crops end in May and June, for in September and October fresh supplies of tea from the interior of the country reach Canton.

The mode of manuring these plantations differs much in different parts; in China, however, the most usual manure is a compost of human excrement and calcareous clay. We everywhere see in the Chinese fields close to the cultivated land, large walled-in pits or enclosures sunk in the ground and filled with this compost. In Japan according to Siebold's statement other very strong manures are used for tea, viz., the expressed juice of the Japanese mustard dried anchovies, also the oil-cake of *Brassica orientalis* and other plants.

The leaves of the tea plant, when freshly plucked, have nothing of the odour and flavour of the dried leaves; they have neither a sharp, nor an aromatic, nor a bitter taste. The properties which they afterwards show as prepared tea, and for which they are so highly prized, viz., the pleasant taste and delightful odour, are the effects of the roasting by which the leaves are

* From "Outlines of the Geography of Plants: with Particular Enquiries Concerning the Native Country, the Culture, and the Uses of the Principal Cultivated Plants on which the Prosperity of Nations is Based." By F. J. F. Meyer, Ph. D., M. D., late Extraordinary Professor of Botany in the University of Berlin, &c. Translated by Margaret Johnston, London, Printed for the Ray Society, 1846. The original German was written in 1836.—A. M. F., Jr.

dried. We need wonder the less at this as it is the same with the coffee. Every one knows that unroasted coffee possesses nothing of the pleasant aroma and ethereal odour which are proper to it after being roasted. The tea leaves are dried upon great iron plates, which are excessively heated, and in large flat iron pans by being constantly stirred with a gentle heat, and are then gradually dried by keeping up the heat. After this the hot leaves are turned out upon mats and rubbed with the palms of the hands; after having cooled they are again put in the pans and again roasted until the tea is perfectly dried, which is done by repeating this operation from four to six times. In drying the leaves lose three-fifths of their whole weight, so that 3 lb. of fresh leaves produce only 1 lb. of dry tea. The differences in the colour, shape, and pubescence of the dried tea leaves at first induced botanists to think that the green and black teas were prepared from different species; this, however, is not the case, but both kinds of tea can be made from the leaves of the same plant, as Abel learned during the journey of Lord Amherst. But when once prepared, the tea, as Mr. Reeves also mentions, cannot well be changed; at least, black tea cannot be made into green tea, though the green may be changed, imperfectly at least, into black.

It is a singular circumstance that the dispute amongst botanists whether tea is made from one species of the genus *Thea*, or from two different species of this genus, has never yet been terminated. In Japan, where black as well as green tea is made, the tea shrubs according to the observations of Kämpfer, Thunberg, and Siebold, belong to the same species, of which F. Nees von Esenbeck also has convinced himself from the specimens brought home by Siebold; consequently the opinion so sharply expressed by Mr. Reeves, formerly tea-taster at Canton to the English East India Company, that the black and green teas are obtained from two perfectly different plants, is shown to be incorrect. *Observation.*—I do not think that more importance can be attached to the opinion of Mr. Reeves, even though he has lived so long at Canton and Macao, than to the botanists by profession, who must know better what are to be considered as species and what as varieties. Besides, Mr. Reeves has never been in the provinces of China, where the culture of tea is universally carried on; nay, he does not even seem to have once visited the tea plantations in the neighbourhood of Canton. Mr. Reeves wonders how any one, who has been in China, who has only seen the different infusions of green and black tea, can consider both kinds of tea the leaves of one and the same plant, and this expression which we must consider very extravagant, seems to find great approval. But had Mr. Reeves known how the different kinds of tea are prepared, he would no longer have wondered. He refers us to the figures of the two sorts of tea which are given in Loddige's Bot. Cab. Tab. 226 and 227, and remarks that the two species, which furnish the black and green teas, are there very well characterized. But that this is not so very extraordinarily clear as Mr. Reeves thinks, will perhaps be confirmed by the unprejudiced comparison of most botanists. Even in our agricultural plants of the kind, which have but small areas, in comparison with the tea-plant, greater differences between the varieties than we find here may be pointed out. It is true that Hooker also has admitted the existence of two species of tea, but his characters are founded on plants which had been grown in England.

If we take a number of leaves of all the various sorts of tea, which come to us in trade, soften them in hot water and lay them out side by side, we shall soon be convinced that there are no characters which distinguish the different kinds of black tea from the green teas: provided a great number of leaves be observed. Accum, who is at present at Berlin, has lately executed and laid before the society for the advancement of Industry in Prussia, a work well worthy of attention, by which the transition of the leaves of all the different sorts of tea is shown. The correctness of Mr. Reeves' opinion on this subject may, therefore, at least be doubted; I think that it may even be refuted.

The green tea is prepared in the manner I have already stated; the black on the contrary is made in what is called the moist way. The fresh leaves are laid on large sieves, and these are placed over boiling water, so that the leaves are permeated and strongly infused by the hot steam. After this the leaves are dried on iron frames in the manner previously described. By this infusion with hot steam the fresh tea is deprived of its astringent principals, viz., the gallic acid and tannin: the leaves also in consequence contain fewer of the delightful aromatic particles which are present in green tea in such quantities. Thus, according to the known analysis of chemists, black tea contains less gallic acid and tannin than green tea; nay, the latter alone contains theine, an alkaloid, which the black tea is probably deprived of solely by the infusion with the hot steam.

Although it is now decided that all kinds of tea are prepared from the same species of *Thea*, it must not be thought that all the sorts can be made in one and the same district and from one bush. In one place the black tea chiefly is grown, in another the green tea; here the tea is but little curled up, there very much, so that it becomes quite globular: this is, however, by no means a mark of very fine tea. I do not think that one can be surprised at this, for the same holds good with other agricultural plants with us, of which there are likewise hundreds of varieties. I here call to mind the making of our wine: the vine is almost everywhere the same species; and yet how differently so the wines taste and smell. The tea plantations, the leaves of which are of a particular flavour, are first as limited as the place in which this or that vine of a peculiar flavour occurs; and it is not the case, that the pleasant odour of particular kinds of tea is given by other fragrant substances. However, I here remark, that I have seen large quantities of the flower buds of *Olea fragrans*, which are a real article of trade in China, and are used by connoisseurs to improve the flavour of green tea; but every one mixes this substance according to his own taste. Inferior sorts of tea, which generally do not come to us in commerce, but are kept for home consumption, are prepared by taking entire branches and shoots from common plants and drying the leaves partly with the stalks, partly only stripped off by the hand. The brick-tea is made of this sort of tea. It comes into trade in hard cakes, very like thin bricks, but is chiefly consumed in Northern China, and in the interior of Asia, for example by the nomades in the desert of Cobi, it consists of bad and dirty leaves, mixed with stalks which are glued together by some clammy substance, pressed in the form of cakes and dried in ovens. In using this brick tea some pieces are broken off, and after having been reduced to powder, it is boiled with water or with milk, meal and fat. The Chinese soldiers on the northern frontiers receive this brick tea as pay, and what they do not need themselves, is sold at Kiachta. Indeed this tea is bartered in all parts of Mongolia and in Dauria. Large caravans of camels laden with this tea journey through the desert of Cobi. At an earlier period it was quite usual both in China and Japan to make tea from the powdered leaves.

The oldest work yet known, in which tea is mentioned by a European, is the *Historia Indica* of Maffei, which appeared at Leyden in 1580: yet tea was first brought to Europe by Dutch merchants in 1610. As early as the year 1660 a tax was laid on the sale of tea by an Act of Parliament. In the year 1638 ambassadors from Moscow brought tea as a present to the Czar.

Now that we have become acquainted with the cultivation, the preparation, and the distribution of tea, we shall proceed to the consideration of the immense quantities which are annually produced from this useful plant, and consumed. We know that at present so large a quantity is consumed in England, that more than $1\frac{1}{2}$ lb. must be reckoned for each inhabitant; but the consumption of tea in China must certainly be much greater, for there every one who can drink tea the whole day. However, if we reckon only a pound and a half for each person, as the population of the Chinese Empire is at least 200 millions of souls, we obtain the enormous amount of 300 millions of lb. If

we also take into consideration the consumption of tea in Japan, Oochin China, and the neighbouring states, 450 millions of lb. of this dried herb is probably not too great a sum for the east of Asia. Now think of the mass of fresh leaves and the number of hands which are necessary to prepare this quantity of tea. Of such importance is agriculture in China and Japan for this object only. We do not indeed know with sufficient exactness the quantity of tea which is annually exported from China, but we know what is imported to Europe and the European Colonies. From accurate sources I have calculated the whole quantity of tea exported by Europeans from the port of Canton, at 45,000,000 lb. for the year 1830; to this must be added the tea brought to Russia by caravans, which is said to have amounted in the year 1830 to no more than 5,105,990 Prussian lb.

The large quantity of tea, with which China supplies the Indian Empire by land carriage, is unfortunately not known, and data also are wanting to enable us to estimate its approximate amount; yet to judge from various accounts, the consumption of tea there must be very great. Over all Thibet and in Nepal tea is the common beverage at every meal. But disregarding entirely the quantity of tea which is brought by land carriage to India, yet 50,000,000 lb. are exported to Europe and its Colonies, for which a sum of about eighteen millions of Prussian dollars flows into the Chinese empire, for on an average the teas are worth one-fourth of a piastre a lb. at Canton. We have however, seen in what an exceedingly singular way this immense sum of money is again drawn from the Chinese Empire, but unfortunately it flows into other hands, so that Europe by the use of tea always suffers a considerable loss of gold.

I may mention that of the 50,000,000 lb. of tea which are exported by sea from Canton, and sent by land through Kiachta, not more than about 200,000 lb. are used in the Prussian States, while England consumes 26,000,000 or 27,000,000 lb.*; accordingly England, in proportion to the population, consumes one hundred times more than Prussia.

The culture of tea is now of great importance to the eastern part of Asia, and yet scarcely 100 years have passed since the use of tea became general in Europe; in the meantime the taste of the people for tea is daily increasing, and therefore it may be foreseen that this branch of agriculture in half a century will be a new and important source of prosperity to certain tropical countries.

The chief circumstance to be regarded in introducing the culture of tea into other countries, is the value of labour in them. The preparation of tea demands much labour, and as the value of tea of itself is very small, of course a very low wage can be given for the labour of its preparation; therefore in a country where labours are few and the day's wage high, tea can never be grown with advantage; this is the case with the culture of tea in Brazil, where slaves are so enormously dear. As the average price of a lb. of tea at Canton is about 3s. 4d., the cultivator must sell it at 5s. or 6s. for the merchant who disposes of the tea to foreigners must have about 30 per cent profit after all expenses are deducted, for the Chinese merchant borrows money at Canton at from 20 to 25 per cent, with which he goes to the tea plantations in the interior and buys the crop on the bush for ready money, just as the wine makers buy the grapes with us.

HEMILEIA VASTATRIX.

To the Editor of the Madras Mail.

Sir,—It seems to me that certain facts point to the vapour which rises from decaying vegetable matter as being, perhaps not the cause, but the most nourishing food for the fungus *Hemileia Vastatrix*. We are known that leaf disease is most rampant in the month of September, when after the monsoon

* In the course of the years 1834-5, after the privilege of trading to China was taken from the English East India Company, and the high duty on tea was lowered, about 36,000,000 lb. of tea, according to the newspapers, were coasted

rains a great deal of saturated decaying vegetable matter is on the ground, and the first gleams of sunshine cause the vapour to rise up through the coffee and thus spread the disease. Under good shade trees again, the disease is stayed because the sun does not reach the ground, and evaporation is not so prolific. Again, on weedy estates in this month, I have often remarked that no disease is noticeable, but, after weeding, it becomes far worse than carefully hand-weeded estates in the same neighbourhood, although the weeds may be buried. In freshly weeded soil which has been to a great extent turned, over a great deal of decaying vegetable matter is to be found, viz., roots of weeds, leaves, &c., and the ground being cold, vapour rises rapidly with a little sunshine, and the ravages of the disease are frightful to contemplate. I am no advocate of weeds, and I think that all arguments for them are exceedingly shallow—for instance, that "they take the place of the carpet of leaves that is found in the natural jungle." But nothing can take the place of the carpet leaves (who ever found weeds in good jungle?) in keeping the soil moist in hot weather, and weeds certainly only help the quicker to exhaust the humus with their long roots, for they must have moisture to grow, and when they are full out, they instantly dry up, and all moisture is lost. But why should there not be a carpet of leaves on a coffee estate, where we have a thin jungle of shade trees, and a heavy under-growth of coffee, which are constantly shedding their leaves. If an estate is worked properly then there will always be a carpet of leaves in the hot weather, when it is required. I argue that in May, June and July, manure should be applied, and the ground scraped free of all weeds and leaves which should be buried with the manure. During August and September no weeding should be done (as this makes the decaying matter which starts leaf disease), but weeds should be prevented from seeding by a careful grass knifing late in September, and if absolutely necessary, in October a clean hand-weeding should be done. As we are now past the leaf disease months, the weeds, and not leaves, should be buried in; and if hand-weeding is persevered with there will be a thick carpet of leaves by the end of crop time, as the coffee drops a large quantity of leaf then, and the pruning will help to cover the ground. Weeds will not grow so prodigiously if the ground is covered, and during the hot weather the hand-weeding must be persevered with to eradicate the weeds, if possible. This form of cultivation will keep the ground free from decaying matter during August and September, the worst leaf disease months, and the estate will be comparatively free from it.

WYNADIIEN.

Saultan's Battery, 29th Aug.

VEGETABLE PRODUCTS IN VERA CRUZ.

The growth of Tobacco in the State of Vera Cruz is said to be increasing considerably, the present production amounting to nearly 6,000,000 lb. per annum, and the average cost being about 5½d. per pound. About 23 per cent. is exported to foreign countries, and of this export somewhat less than half is of manufactured tobacco, and comes chiefly to England, the remainder is consumed in the Republic. For the highest quality of tobacco as much as 10s. 6d. per 100 leaves has been obtained, but this quality is very scarce. Notwithstanding its primitive method of cultivation, Vera Cruz Tobacco is obtaining—and deservedly—a rapidly increasing reputation, and the tobacco manufacturers of this part are increasing the size of their factories and the number of their operatives, and paying greater attention to the selection and the sorting of the leaves, and are, in fact, producing a very superior article to the Vera Cruz cigar of two years ago, or even of last year. This improvement in the manufacture will, of course, increase the market, and also give great encouragement to the planter; but what is chiefly wanted is capital, combined with the better cultivation which is so necessary, but so difficult to obtain, in the present financial condition of the majority of planters.

VANILLA.—The vanilla bean grows wild in the cantons of Misantla and Papantla, and it is also cultivated there in a primitive manner by the Indians. It is prepared for market by the cultivators and collectors, and often before it is quite ripe. This is especially the case with the wild Vanilla, one family taking it early lest another family should get it when quite ripe for harvest. The systematic and rational cultivators of Vanilla in the cantons just mentioned would certainly be a remunerative business. At present the quantity produced is about 8,000 mils (*i. e.*, 1,000 pods), worth about £3 to £3 10s. per mil.

FRUITS.—The fruits of the State of Vera Cruz are of great variety, and grow in such abundance as to be exceedingly cheap. The production of Pine-apples is about 500,000 per annum; they are grown in fields, and their local value is about 1*d.* to 1½*d.* a piece. Plantains are a fruit universally consumed, and over 10,000 per annum are actually harvested; their local value is less than 1*d.* per 10 lb.

PITA FIBRE.—This fibrous plant grows wild in Vera Cruz, and can be cultivated with very little care. Its fibre sometimes measures 3 yards long, and is very silky in appearance; but unfortunately its preparation for market is at present difficult and expensive. The State Government is, however, about to offer a large reward for a machine to reduce Pita to a marketable state without injuring its beautiful fibre, and without making its cost of production too high, having regard to its market value. It is most probable that such a machine will be produced, and if so, Pita will become, undoubtedly, the first article of produce and export of this State.—*Gardeners' Chronicle.*

THE PONDICHERRY GROUND-NUT TRADE.

(From a Correspondent.)

The Ground-Nut season for Pondicherry and South Arcot has practically closed for the year 1888, and arrivals both by rail and road have stopped; two, or possibly three, steamers have yet to load, either wholly or in part, from Pondicherry, and with these the stocks will be cleared out. The crop has been a fairly good one, especially when the damage occasioned to the sowings by the prolonged and heavy North-East monsoon of 1887 is considered. But for this misfortune the harvest would have been an unusually heavy one and cultivators and the host of "middle-men" would have had to accept lower prices and diminished profits. Curiously enough, the exceptionally high prices at which the local markets opened at the beginning of the year have been fully maintained throughout the season, notwithstanding the unfavourable rates prevailing in Europe. It is a notable fact that while the average local prices for the three years preceeding 1888 varied but slightly, those for the current season advanced nearly 20 per cent. on former figures. The following is an approximate statement of the Pondicherry export market rates *per French candy* of 240 kilos or 529 lb. English, for the seasons of 1885, '86, '87 and '88:—

	1885	1886	1887	1888
Opening Prices	14 0	15 0	15 8	18 8
Closing Prices	19 4	19 0	20 8	25 8
Highest Price touched	21 8	20 0	21 0	26 0

No reliable statistics have, I believe, been obtained, by which even a fair approximate of the cost of producing the nut can be arrived at; different cultivators differ in their figures even as much as 50 per cent. the minimum being fixed as low as R8 per candy and the maximum as high as R12. Probably an average of R10 per candy would not be very far wrong. Allowing for the losses sustained on low lands in consequence of the heavy floods of last year's monsoon, there must have been a very large average profit on the actual cost of production throughout the district, and it is not to be wondered at that this year's sowings are said to be largely in excess of any previous year, so that if nothing unforeseen happens the total output of Coromandel kernels will not fall much short of 1,500,000 bags, giving about one-and-a-quarter million of foreign export. It is scarcely, how-

ever, to be expected that with a largely increased crop the current season's high rates will be maintained, and unless the foreign Bombay and Senegal supplies fall short, or the manufacturers requirements are unusually heavy, Indian cultivators may have to accept greatly reduced prices in order to effect sales. Growers may be expected to stand out for a time against lessening rates below last year's values, but ground-nuts deteriorate rapidly and, in rainy weather, unless carefully stored in dry godowns, begin to germinate and soon become worthless as an article of export. Under such circumstances, therefore, holders of large stocks of such risky goods will do wisely to accept moderate profits and quick returns.

The following statement shows the total number of bags exported from ports on the Coromandel Coast to foreign countries, from the year 1885 to 1888 both inclusive:—

	1885.	1886.	1887.	1888.
Pondicherry,	} 614,229	} 851,132	} 870,498	} 950,000*
Cuddalore ...				
Madras ...				

* estimate in part.

The bulk of the trade is transported in English steamers. Of the total exports during the three years ending December 1887, British vessels carried about 80 per cent. and French about 26 per cent. Nearly the whole of the earth-nut exports from Madras ports go to Marseilles. For the period above referred to France took 90 per cent of the total.—*Madras Mail.*

COCONUT AS A VERMIFUGE.

TO THE EDITOR OF THE TIMES OF INDIA.

Sir,—I was not a little surprised to find that so well posted a journal as the *Lancet* should be found informing its readers that the coconut may ultimately prove as efficacious as a vermifuge as Professor Parisi, of Athens, found it to be during a recent visit to Abyssinia. Coconut has been used as a vermifuge in India for probably forty generations by the beef-eaters in this country, and is so well known as a vermifuge for expelling the flat worm that I cannot conceive that the news of this use of the coconut should have reached England only a month ago. Much has recently been written about the advancement of therapeutics and pharmacology in this country, and a great desire has been expressed to bring to light the properties of the indigenous drugs of this country, which are known only to the *hakems* and the *bairis* of India. What we chiefly want appears to be an Indian Pharmacopoeia to be published by Government on the lines of the British or, better still, the American Pharmacopoeia. Such a work was begun in Calcutta by Dr. O'Shaughnessy about thirty years ago. The work has probably become extinct, but I remember how useful it was to medical men in this country. It could be easily revived if Government would only direct that this should be done, and would pay a compiler for preparing it. The number of known Indian drugs, whose properties have been well proved, are sufficiently numerous to make up a good sized and very valuable pharmacopoeia. The discovery by an Athenian professor of the vermifuge properties of the coconut, and the commendation given to the professor's discovery by the *Lancet*, go far to prove that India should possess its own pharmacopoeia, not only for its own benefit, but also for the benefit of European nations. The flat worm prevails in Europe from the extensive use of beef and swine flesh in these countries. The most abominable vermifuges are employed for their expulsion, of which male fern oil, koussou, the root of the pomegranate, and turpentine are the chief. Compared with any of these vermifuges, the coconut vermifuge is as pleasant to the palate as the others are offensive, and, when properly prepared and intelligently administered, is equally efficacious. Now why should thousands of persons in Europe suffer themselves to be barbarously physicked by the abominable vermifuges I have named, when the coconut vermifuge is within easy reach? The answer appear to be, because there is no Indian pharmacopoeia. There are numerous other very effica-

cious drugs known to the Indian *hakem* and *haid* and constantly used by them, but often used in a hurtful manner from a deficient nosology and an incorrect diagnosis. These drugs are not usually found in chemists' shop in Bombay; but they would be found there if there was an official Indian pharmacopœia, and I have reason to believe they would prove a very useful addition to the armamentarium of the practising Indian physician. And if to the practising Indian physician why not to the European practising physician, and to humanity in general? Do I ask the Government of India for a great mercy or a very small one? Financially I ask for a very small mercy indeed, but that very small mercy is capable of becoming a very great mercy to human suffering.—E. —*Times of India*.

NEWS FROM TASMANIA.

TASMANIA, 24th July.—I send a small packet of celery-top pine seed (*Phyllocladus rhomboidalis*), a noble pine, indigenous to Tasmania, growing freely in the wettest though not the coldest portions of the island, furnishing the timber that has the remarkable quality of being *unshrinkable*. As the season advances I hope to get Huon pine and other seeds in quantity. Meanwhile we are in the depth of winter. Yesterday morning the ice was an inch thick and the ground white; at Waratah the snow was $\frac{7}{8}$ inches deep, and the wind blew as cold as ever I felt it at Dover or Dunnet Head. Phew!—for all-the-year-round comfort, commend one to the hills around Kandy.

Garrulous globe-trotters may talk as they like to a gullible public about this "perfect" climate. As for me, I am disposed to say as Pere Acolti the missionary said of Vancouver: "huit mois d'hiver et quatre d'enfers" —does n't suit.—*Cor.*

From a letter contributed to a local paper by "Old Colonist" evidently, we quote in regard to Roadmaking in Tasmania:—

Some months ago about 150 so-called "working men" were despatched from Hobart, passage paid, to Strahan, the ostensible object being the construction of a road from Rannine to Zeehan, the remuneration 8s 4d per day of eight hours. A few days after reaching their destination, these "working" men might have been seen in groups, stretched on the banks of the River Henty, busily smoking and playing cards, while a team of poor lanky bullocks struggled helplessly to drag their traps through the sandy bed of the river. "Come! hear a hand," cries the bullock driver, but not one would move. "We ain't going to wet our feet for any — boss," was the response. The thoroughly reliable eye-witness who graphically depicted this scene, adds that he had seen gangs of these men pass to "their work," the day being well advanced ere they started, midday would be past by the time they reached the supposed scene of operations, when shrewdly calculating that they could put in the eight hours by the time they again reached the butts, they actually returned without ever soiling their shovels, chuckling greatly over the joke.

Meanwhile the local "boss" would doubtless be leaning back in his easy office chair, inditing the weekly report to his chief in Hobart, in which he had "the honour to state" that strenuous efforts were being made to accomplish the work in hand, and that no stone was being left unturned in order to complete the road to Zeehan with the least possible delay.

On the margin our correspondent pencils:—

On the mines the manager tells me he is now paying regular wages to all owners at the rate of 10s for eight hours, and paying all cost of carrying provisions. How many S. D. get this in Ceylon? Why it is — (Rs 200) a year, but then Raman is a gentleman compared to the average miner.

COCONUT REFUSE AS A DEFENSIVE WAR MATERIAL.

When a local controversy raged as to the merits of coconut refuse in agricultural and horticultural operations, it must have been the last idea which could have occurred to the local disputants, that the substance of their contradictory opinions was calculated to play an important part in the defensive armour of ships of war! And why, if it succeeds at sea, should it not be found useful on shore as a substance in which the cannon-balls of an enemy attacking Colombo or Trincomalee might be buried as they struck, the compressed coir dust closing over them? The paragraph we are referring to occurs in an unexpected but not incongruous place, Dr. Lawson's report on the Nilgiri Gardens. The Mr. Money who brought the French account to Dr. Lawson's notice and helped to conduct experiments is the former Calcutta lawyer who has been long a planter on the Nilgiris, and whose book on Java, "How to Govern a Colony," produced a sensation when it appeared. The paragraph is as follows:—

A Proposed New Method for Utilizing Coconut Refuse.—Mr. J. W. B. Money of Deva Shola drew my attention last summer to an article entitled "Batiment de combat et la guerre sur mer" in the *Revue des Deux Mondes*, dated the 1st August 1886, by a M. L. P. de la Barrière in which he described, at length, how the refuse of the coconut, after the process of retting, might be used for backing the iron plates of ships of war. His mode of proceeding was simple enough, and is as follows:—He took a quantity of the powdered refuse before it was quite dry, and subjected it to pressure, when the natural viscidness of the macerated cellular substance of the coconut caused the mass to cohere, and the whole to form a plate which in general appearance was like a mill board, only much more brittle; owing to the hygroscopicity of this substance, if a hole is made through it, the parts adjacent to the puncture absorb water, swell up, and immediately close the orifice. When on the West Coast last August, I brought away a sack of this refuse, and made a plate, eighteen inches square, by about $\frac{1}{2}$ of an inch in thickness, and placed it between two boards, and then fastened it to one side of a box, which contained a head of one foot of water. A bullet one-half inch in diameter was fired through it, but not a drop oozed out. This experiment was repeated three times with the same result; next a $\frac{3}{4}$ -inch bullet was fired through the plate, when a few drops only made their way through; lastly a bullet near an inch in diameter was fired through the plate, when a large jet of water shot through, but in the course of a few seconds the stream decreased in volume; and in less than a minute had ceased to flow altogether. Whether or no this material could be advantageously used for the purpose which Monsieur de la Barrière has suggested, or for any other purpose, it is a matter worth considering; for, as Monsieur de la Barrière truly says in his article, millions of tons float away annually down our rivers in India. All the above experiments were carried out under the superintendence of Mr. Money, on his estate at Deva Shola.

CINNAMON AND COCONUTS IN THE NEGOMBO DISTRICT.

Kadirana, 22nd Sept.

Weather still dry. Since the 25th June, now close on three months, we have had 171 inch of rain, so you may imagine the parched state of all shrubs and grasses; the showers that fell on the 17th and 18th, about half an inch, freshened up the herbage a little and cooled the atmosphere for two days, but matters are as bad as ever again. Cinnamon in the white sand fields especially, is suffering severely, and the bearing of coconut trees for next year's June, July, August and September pickings will be very seriously affected. Pools and springs are rapidly drying up, and altogether prospects do not look encouraging. I should like to lightening towards the north this evening, — an indication, I hope, of the advent of the north-east monsoon.

CEYLON AT THE MELBOURNE EXHIBITION.

77 Collins St. West, Melbourne, 7th Sept. 1888.

The Secretary, Planters' Association, Kandy, Ceylon.

Dear Sir,—I am in receipt of yours of the 3rd and 4th ultimo advising despatch of the exhibits and the two native attendants by S. S. "Oceana" which reached this on the 21st ultimo, after which I continued as expeditiously as possible to complete the arrangements for the Court; further exhibits however from Messrs. Mackwood & Co. which came to hand by German steamer, arriving several days later, have retarded somewhat the completing of the Court, and I am unable to advise by this mail its being open to the public, but can confidently say that I shall be in a position to do so by the next; and I hope your Committee will agree with me that it was preferable to have everything in position before opening though it may have caused a little further delay. I am glad to say that the space afforded me will be ample for all requirements: some of the space allotted, adjoining ours, not being taken up, has been granted to me. I regret to say that permission has not been granted for the sale of tea, and it is highly improbable that it will be,—the last communication with the public caterer now more than a fortnight since being entirely ignored, to whom as I wrote you previously the Commissioners referred me in the matter.

As the outlay so far as has exceeded £175, I need not say that it will be advisable for the satisfactory development of the exhibits that you should remit me further funds. In the meantime I propose in order to meet current expenses to dispose of some of the tea in hand provided that I can do so at a fair profit. Accounts and vouchers of expenditure will be forwarded you by next mail.

I have to request you to thank Mr. A. M. Ferguson for his two letters to Sir J. Macbain and Mr. Cosmo Newbery, which I shall avail myself of with pleasure. The Ceylon flag alluded to in your letters under reply has not been received, but will probably come to hand by the S. S. "Coromandel" due here on the 8th or 9th. I had already had a flag made representing an elephant balancing a flag pole bearing the Union Jack, which can be replaced by that sent by you if thought advisable and made use of in some other part of the Court. I have had some little trouble in finding house accommodation for the two native attendants, but have made the best arrangements possible, and imagine that their discomfort, if any, must be mainly attributed to the continual cold weather they have experienced since their arrival. I having found it necessary to provide them with some extra warm clothing; as we are now expecting daily warm weather, this cause of complaint will be removed.

The photographs received have been nicely framed, so as to fit into suitable positions in the building, and will without doubt be a great attraction, being much admired already.

Should my selling of tea be approved of by the Committee during the season of the Exhibition, I would advise further shipments and in half chests in preference to whole.—I am, &c.,

(Signed) H. MCKENZIE.

CEYLON TEA IN AMERICA:
HOW TO MAKE IT KNOWN: DR. DUKE'S
PLAN—A GOOD IDEA.

We learn that a proposal has been laid before the Planters' Association by Dr. Valentine Duke which is at once novel and, from our point of view—extremely sensible and practical. With the object of securing attention to Ceylon tea throughout America Dr. Duke proposes that the 6,000 lb. of tea offered to Mr. Elwood May under conditions, but declined, should be utilized by being distributed into a thousand or 1,200 packets of 5 lb. tea each. These should be made up in suitable neat boxes which ought also to contain a short account of the rise and growth of the Ceylon tea industry in pamphlet form with

instructions for the proper infusion of Ceylon tea. What is to be done with the boxes? They are to be entrusted to a reliable agent, to forward by prepaid parcel delivery or post to the leading Newspaper Editors in the United States and Canada! This is to be effected so that the delivery may take place as "A CHRISTMAS GIFT from the Tea Planters of Ceylon" to each of our selected Newspaper contemporaries. So good is the idea that we should like to see it extended and 2,000 additional packets of 2 lb. each say, sent to the conductors of second rate journals—whose name is legion—in the States. That would make 10,000 lb. of tea in all, and a better advertisement for our staple across the Atlantic "ferry" could not possibly be desired. A good paragraph, if not a leader, with full extracts from the pamphlet, might be looked for in the journal of every recipient, and as 5 lb. or even 2 lb. of good Ceylon tea—equal to double the quantity of China—would suffice for a considerable time in the editor's family, the lasting effect of the advertisement in a circle sure to have many friends and acquaintances can be easily understood. Dr. Duke, we believe, urges that the editors of medical and technical journals should be specially considered in the distribution. This can easily be done. From Sell's Dictionary of the World's Press, we gather that the totals for the United States and Canadian Dominion are as follows:—

Daily Newspapers	1,297
Tri-weekly	"	...	51
Semi-weekly	"	...	173
Weekly	"	...	11,165
Bi-weekly	"	...	74
Semi-monthly	"	...	252
Monthly	"	...	1,674
Bi-monthly	"	...	26
Quarterly	"	...	127

Grand Total ... 14,339

It will be no easy matter selecting even 3,000 out of this large body of press publications; but the agent employed—and it is much better to entrust this duty to someone in America—has the means of ascertaining approximately the position of nearly every journal in the country. Sell gives the names and addresses of only about 800 with the leading circulation, and this "Dictionary of the World's Press" (for 1887, the latest published) is at the disposal of the Planters' Committee if they desire to have it. But we would strongly recommend the gentlemen concerned to entrust the business of distribution to capable and disinterested hands in America. Perhaps it might not be thought the right thing to give the distribution to any dealer in tea? In that case we would recommend to the notice of the Tea Fund Committee the firm of Messrs. Pettingill & Co., Broadway, New York, who stand highest, we believe, as Newspaper Advertising Agents, and who must have business connections with all parts of the Union. A gentleman who would be certain to interest himself, if applied to, is Mr. Andrew H. Green,—brother of the late Dr. Green of the American Mission, Jaffna,—who holds a very high position in New York, at the head of one of the largest Insurance Societies, and who bears the highest reputation as a citizen, man of business and politician. A word from Mr. Green in any business circle in New York goes a long way, and we know how he keeps up his interest in Ceylon affairs. It will be for the Planters' Committee, however, to decide what is best to be done with Dr. Duke's proposal. That it is likely to be taken up cannot be doubted, since we learn it has the approval of several of the leaders of the planting community.

COLONISING EAST AFRICA: THE BRITISH EAST AFRICA COMPANY:

THE B. E. A. COY. TO HAVE 50,000 MILES.

We reprint today from the *London Gazette* of last night the text of the Charter which has just been granted to the Imperial British East Africa Company. We also print a long account, from the pen of a well-informed correspondent, of the character, purposes, and prospects of this new and very important enterprise. The Charter has been issued in response to the petition of Mr. William Mackinnon, Lord Brassey, Sir Donald Stewart, Sir John Kirk, and others—men whose character and reputation are a sure guarantee that the great work undertaken by them in the foundation of the British East Africa Company will be pursued with energy, discretion, and humanity. The territory to be administered and developed by the Company has been obtained by formal cession from the Sultan of Zanzibar and from a large number of independent or semi-independent chiefs in the interior. It lies wholly within the region recognized by agreement between this country and Germany as reserved for the exclusive exercise of British influence in that portion of Eastern Africa. Starting with a strip of coast line, ceded by the Sultan of Zanzibar, about 10 miles broad and 150 miles long, including the important and very valuable harbour of Mombassa, it stretches inwards in the shape of an irregular wedge, which has its apex on the eastern shore of the Victoria Nyanza. Its northern boundary is the River Tana from the coast for some distance inwards, though it ultimately quits that river and turns considerably to the northwards before reaching the Victoria Nyanza, so as to include the northern slopes of Mount Kenia; and its southern boundary is the line of demarcation already agreed upon between the respective spheres of British and German influence. There seems, however, to be room for an amicable rectification at certain points of this somewhat hastily drawn boundary, and it is to be hoped that this matter may be adjusted without delay, and that no troublesome questions may be left in abeyance, to give rise to dispute hereafter, when British and German enterprise have established themselves within the respective spheres of influence of the two Powers.

The territory thus formally handed over to the new Company has an estimated area of about 50,000 square miles and an estimated population of about two millions. It is known to include some of the most fertile and salubrious regions of Eastern Africa, and there is every reason to believe that its exploitation and development will, in time, reclaim a vast area for civilization and amply repay the efforts of those who have undertaken the task. At the same time the magnitude and difficulty of the task must not be underestimated. The coast and the country for some distance inland are known to be far from healthy. It is not until the elevated plateau of the interior is reached that the fertile and salubrious districts are found which have been described almost as a Paradise by those European travellers who have visited them. It is hardly safe, perhaps, to take too literally the enthusiastic descriptions of explorers and discoverers. But, when all reasonable deductions are made, there seems to be no doubt that the upland regions which lie between the Zanzibar coasts and the Equatorial Lakes are eminently adapted for development by European enterprise. It is possible, indeed, that the unhealthiness of the coast may have been exaggerated. The routes to the interior, which have hitherto been mainly used by slave traders and their caravans, seem to have been deliberately established in places

so unhealthy that the slave-traders were not likely to find their passage disputed by robust and warlike tribes. If this be so, however, the circumstance is not likely to constitute one of the initial difficulties of the new Company. The Company is required by its Charter to discourage and, so far as may be practicable and consistent with existing treaties, to abolish, any system of slave trade or domestic servitude within its territories. It will, therefore, find the whole slave-trading interest opposed to it from the outset; and that this is no contemptible obstacle to its enterprise seems to be shown by the news, which reaches us this morning, of a conflict which has just occurred between the boats of the German gunboat "Möwe" and a force of discontented Arabs and natives at Tanga, near Pangani, a place on the Zanzibar coast, within the territory of the German African Company. The "Möwe" has found it necessary to shell the town, and a good deal of excitement seems to prevail in the district, though the presence of a German fleet in the neighbourhood will probably suffice to prevent any serious disturbance. Discontent with the procedure of the German Company is said to be the cause of the outbreak, and this may be regarded as an example of the kind of opposition which the British Company is not unlikely to encounter in its turn. Nor will its difficulties be confined to the coast. A considerable portion of the uplands of the interior is occupied by the warlike Masai tribes, who are said by our Correspondent to be the scourge of the whole region. "They are," he says, "perpetually carrying slaughter and devastation among their neighbours, stealing their cattle, and redering anything like settled industry impossible." The presence of these irritable and warlike savages is undoubtedly an obstacle to the immediate civilization of a district otherwise eminently adapted for the peaceful and beneficent processes of European enterprise. But it is not an insurmountable obstacle. The colonization and commercial development of a new land peopled by savage races is never an easy task. But it is a task which Englishmen have undertaken over and over again and always accomplished in the end. Certainly the task has not often been undertaken under better auspices at the outset or with better prospects of ultimate success than those which the Imperial British East Africa Company now enjoys.

It is no small matter that England is now definitely committed to a share in the work of carrying European civilization into the recesses of the Dark Continent. It may be that this will hereafter be regarded as one of the great achievements of the nineteenth century. The issue of such an undertaking are as yet literally incalculable. Africa, especially Eastern Africa, seems to be like a fruit with a rough and forbidding rind and a sweet kernel within. There is no calculating as yet what the full value of the kernel may be when the rind is once penetrated and stripped off, but there is no reason to think that its value has been greatly overestimated by the few who have been permitted to taste it. It is likely enough that, although Africa has been the last of the great territorial divisions of the earth's surface to yield up its secret and its treasures to European curiosity and enterprise, it may yet prove in the end to be as rich as any, and may surrender more rapidly and completely to the peaceful conquests of civilization. The resources accessible nowadays to those who attempt to explore and develop a new country are far greater and more potent than at any previous period of the world's history. It is, indeed, when we come to undertake a task such as that which

battled and almost defeated the sturdy adventurers of the Elizabethan age when they strove to lay hold on the New World, that we begin to appreciate those appliances of material civilization whose praise was so eloquently sounded by Sir Frederick Bramwell a few days ago. It may be that the difficulties which the new Company will encounter in the first beginnings of its enterprise will be as great as, or even greater than, those which tried the endurance of the first colonists of Virginia. But we now enter upon the struggle with resources infinitely more potent. It is not wise to boast at the beginning of a great enterprise, still less to be over-confident of immediate and brilliant success. The fortunes of the new Company will probably undergo many vicissitudes. But, if the reports of those who have seen the promised land are even approximately true, there can be little doubt that the founders of the British East Africa Company have set their hands to a work big with the fate of many generations of the English race.

Among the native products of the districts adjoining the Zanzibar coast regions are indiarubber, of at least two species, copal, hides, grain, orchilla, oil-seeds, copra. The Somali country has great commercial capacity. Although the islands of Zanzibar and Pemba are cultivated in the rudest possible manner, they furnish a large proportion of the clove supply of the world. Quite recently tobacco of the best quality has been grown by the German planters. The forests are full of springs and deep deposits of alluvial soil which affect even the natives. The Taveta forest is 15 miles by three, and when it is cleared the fertility of the soil will be almost inexhaustible. All travellers speak in glowing terms of the fertility of the plateau (2,500 ft.) to the west and south-west of Taveta, around Kilimanjaro; not only are there abundant native products, but anything will grow one chooses to plant. Germany has here 2,000 square miles of the very best land. The natives are great bee farmers, the district yielding about 100 tons of honey and wax annually.

As to the southern portion of the Taveta plateau, very favourable reports are given of its agricultural possibilities. It has an altitude of 2,500 ft., rising gradually for 100 miles towards the north-west. The plateau is about 50 miles wide. Though not particularly well watered, as is shown by the absence of large trees, it is covered with pasture. The region is reported to be to all appearance well adapted for wheat culture. It has the necessary elevation, a soil suited for the purpose, rain sufficient to mature two crops of fine grass annually. Still, the real capacity of the great southern plain, and an even more extensive one to the north, must be practically tested by those familiar with Indian modes of culture; those who know the facts are confident of the result.

The south Masai plain has a very large area available for cultivation. The climate is colder than the Taveta plain, the temperature ranging from 52deg. to 72deg., only rising to 80deg. in the hottest part of the day. Of course, it should be remembered that all these conclusions are based on very limited observations, and much yet remains to be done before a satisfactory knowledge of the country and of its capacities has been obtained. The country, so far as these high plains or plateaus are concerned, is stated to be "one of the most salubrious in the tropics—probably in the world;"—capable of becoming a permanent settlement of British colonists and a new centre of trade. This, it must be admitted, is a strong statement to make, but it can be easily tested, and no doubt soon will be.

There is, however, a far more extensive plateau

to the north of this, possessing to a high degree all the essential conditions of soil and climate suited for wheat culture. Mr. Thomson, indeed, describes the climate as very similar to that of Europe. The plateau begins at the south end of the Mau encampment and strikes away north-west to the Victoria Nyanza. It has an average height of from 3,000 ft. to 4,000 ft., with a greater and more regular rainfall than the southern plain, but is not too wet for wheat. It is more wooded than the Masai plain, and has a population of robust and independent agricultural tribes, able to hold their own against the Masai. It is admitted by those who have visited and studied the country that there would be no difficulty in making a railway to the plateau over a distance of 300 miles through the heart of the Masai country. But it is premature to discuss such a project. The country is reported to be admirably adapted for the construction and cheap maintenance of a railway. It may no doubt be some time before the region is ripe for extensive railway construction, but if wheat culture is to be carried out on an extensive scale a railway will become necessary. There would be a few preliminary difficulties in the coast region, after which it would be comparatively plain sailing. It would bring what is believed to be a wheat country of great extent within less than a day's journey of Mombassa. Ivory alone, of which no doubt a fair supply now exists, may soon be difficult to obtain, though the company will take stringent measures to prevent the diminution of the present supply. Besides wheat, the country is capable of producing tea, chocolate, coffee, vanilla, pepper, tobacco, opium, carob beans, cinchona, wines; while among native products there are Indian corn, hides, rubber, cotton, copal gums, wax, honey, aloes, fibres, oil seeds, orchilla. Manufactured goods of various kinds could be introduced and exchanged for these products at a very handsome profit and yet with perfect satisfaction to the natives.

A recent report refers to the region in the following glowing terms:—

All the mixed beauties and grandeur of the Alps, the vastness of the Himalayas, are there blended with the delicacy and softness of the finest parts of our English lake scenery, with a harmony so perfect that once seen it can never be forgotten even by the least impressionable. To whichever aspect the spectator may turn, the eye is enchained by the almost ideal loveliness both of the foreground and ever varying distance; the shadow of each passing cloud, as it floats across the splendid snow-clad peaks of Kiboo and Kimawenzi, which stand out isolated in the sky nearly four miles above, brings with it a constant change of hue over hill and plain, lake and stream, as well as over the ever-green tropical foliage which lends its charm to every feature of the more permanent landscape. This exquisite picturesqueness is probably caused partly by the extreme purity of the air, but principally by the presence at one spot of so great a variety of scene, each perfect of its kind, and all within the spectator's range at the same moment, every detail, moreover, being subject at short intervals to an entire change of light and shade, while to the harmony of each prospect an indescribable grandeur is added by the perfect contour of the isolated cone which crowns the whole. The eye may tire of the daily prospect of the everlasting snow walls and peaks of Northern India, or of the less vast but more varying mount and vale, gorge and precipice of the Swiss Alps, but here even the natives carrying the loads of the expedition seemed never to lose their interest in the scenery, and, after camping for a month amid it, Europeans will still sit, without wearying, gazing for hours on the splendid peaks, precipices, and craters of this mountain, and on the evergreen but ever varying vegetation which clothes its slopes,

The whole transaction which has led to the formation of the Imperial British East Africa Company and the granting of the charter has been carried out with credit to all concerned; but the fortunate result is without doubt largely due to the energy and business capacity of Mr. William Mackinnon.

Mr. George S. Mackenzie, who has had a long and varied experience of the Arab and Persian tribes in the Persian Gulf, has left for East Africa for the responsible duty of taking over the concession from the Sultan and inaugurating this important work. He takes with him a well-selected staff of Englishmen, whose qualifications fit them for the work, and the operations of the company will be commenced at once by the despatch of a well appointed caravan to open up the interior to European trade. Already one has been sent up the country, and with the energy, capital, and experience which direct the great enterprise we may hope at no distant date to be able to measure results in proportion. And, while every Englishman will feel proud of the success of an undertaking so distinctly characteristic of British enterprise, not the least sentiment of national gratification will be that which arises from the hope we may now feel that we are within measurable distance of the end of the unholy slave traffic of the dark region into which the light is now about to enter.—*London Times*, Sept. 8th.

A DAY IN A CEYLON TEA FACTORY.

My chief object in Ceylon being to see what I could of the tea-planting and the manufacturing industry of the same, I made my way upcountry from Colombo at once to the estate to which I had secured an introduction.

I arrived between eight and nine in the morning, and found work in full swing; the gentleman who superintends the tea-making was already in his office—a small room adjoining the store, and having windows on every side to overlook the engines. He received me very courteously, and seemed delighted to show me everything, but offered first to explain the method which was pursued with the leaf before it reached the factory.

"Our principal work," began Mr. S., "is the plucking of the leaf, which goes on for a good part of the year. This is done by my coolies, who pick the leaf into small baskets tied at their waists. They empty these into larger ones which are taken twice a day to my assistant's bungalow (he lives a mile from here, in the middle of the tea garden) and weighed, after which they are poured into a cart fitted with trays, and brought down here."

"How often do you pluck the trees?" I asked.

"We go over the estate about every eight or nine days. We pluck the unfolded leaf or tip at the top of the shoot (which makes the bright yellow tip seen in the higher class teas) and the two next leaves, according to the season. Women are the best pluckers; they get the most practice, as the men are often taken off for other work."

"When the leaf reaches the factory your work begins, I suppose?"

"If you will come round and have some breakfast with me, we shall just be in time to get before the leaf carts come in," he answered; and I gladly followed him to a pretty little bungalow, covered with creepers, not a hundred yards from the store, where a very clean and attentive servant, dressed all in white, had spread an excellent breakfast in the one sitting-room—a fairly large one, with a lovely view.

The Fish Club, which has a box up from Colombo once a week, had provided a capital dish of fish, very like salmon, but white-fleshed; besides this, we had buttered eggs, a "devil" of a peculiarly Singhalese warmth, and a fine sirloin of beef, cold, with a salad, which my host said he raised from English seed, and of which he had only one complaint to make, that it

would grow to such a gigantic size that it took him a week to get through one lettuce. Our beverages were beer, and whisky and soda; for a second course we had tea, toast, and jam, the former very strong and of a delicious flavour.

On going down to the factory after breakfast, we found a leaf-cart, drawn by bullocks, had just arrived.

"The first thing to do," said Mr. S., "is to see that the quality of the leaf is all right; if I find any hard or coarse leaf, I make the coolies pick them out."

The upper floor of the factory was filled with coarsely woven cloths, called Jute-Hessian, stretched from side to side of the store, one sheet six inches above the other, leaving just room for a man to pass at ends and sides.

On these tats, as they are called, the leaf is spread, very thinly, a pound of leaf taking up about ten superficial feet, and there left until it gets soft and flabby and withered. In fine, hot weather this takes place in about eighteen hours; in cold and wet, double the time. When properly "withered," it is swept off the tats, through a hole in the floor into the roller.

"Now let us go down to the lower floor, and see the different kinds of machines. This large press moving rapidly backwards and forwards on a table, is the roller, which bruises and twists the leaf; then it is passed on to the roll-sifter (a horizontal sheet of fine wire netting, moving, by means of a crank, with a quick, shaking motion) where the fine leaf falls through the netting, and the coarse is once more returned to the roller to be further bruised and pressed. The roll (as the leaf is now called) is then spread out on tables, some three or four inches deep, and covered with a damp cloth, is left to ferment."

"And what," I asked, "is that enormous kind of box, with doors and wheels, which suggests a bathing machine?"

"That is the dryer, into which the roll is put when it is fermented, a process of from one to three hours according to the temperature and quality of the leaf. It is put in at the top, and carried along a series of zinc trays working on an endless chain and at different levels, through which hot air is drawn by the fan from the furnace below. The passage through the dryer takes about twenty minutes, and when the leaf is discharged the tea is made."

"But," I objected, taking up a handful of tea from below the dryer, "this is not like the tea one gets in England."

"No; what you are looking at is what we call bulk tea. It has still to be sorted, either by hand or machine-worked sieves, and the tea may be divided into many grades. Here we sift into three grades only. The first which contains those yellow tips I showed you, we call broken pekoe. This, I fancy, you never get unblended at home, and, indeed, it is too strong for drinking alone. After separating the broken pekoe, the rest goes into a machine called a cutter in which knives work to and fro over a perforated plate and the tea which drops through the holes is called pekoe—the second grade. This makes, in my opinion, the best tea for ordinary drinking. The third grade—pekoe souchong—is that which, after the admixture of a large percentage of the commoner China tea, is sold retail at home for 2s or 3s a pound."

"Do you do anything in the way of sending tea home yourself?" I asked Mr. S.

"No; except occasionally sending my people a box for their own use."

"And may I ask what that costs you?" I said.

"Something under 3s a pound, duty and all charges paid and delivered free. For this I can send my people a first-rate strong and flowery pekoe."

"I suppose you have been a long time in the country."

"About ten years," Mr. S. answered; "seven were devoted to coffee and cinchona, and the last three to tea."

"And have you not been home in all that time?"

"No; I always look forward to taking a trip some day, but we are only just beginning to recover from the depths of poverty into which we were thrown by the failure of coffee."

"And when is your day's work finished, and what do you do then?" I asked.

"Everything is usually finished by about four in the afternoon, except in the heaviest crop time, when we sometimes work all night. I have a very good tennis ground behind my bungalow, and on most fine evenings some of the neighbours drop in, and we get a set or two. Also I keep a few hounds; and on wet evenings can generally get a run either with deer, pig, or a hare. My employers, too, are good enough to give me an extra allowance for a horse, so that I sometimes get a ride when, after a long day in the factory, I do not feel inclined to take the necessary exercise on my own legs. If you can manage to stop with me for a day or two, I shall be delighted to show you something of the life."

I was unable to accept this kind invitation just then, but before leaving Ceylon I did go and spend a few days with Mr. S., and enjoyed it exceedingly, obtaining thereby considerable insight into the life of a tea planter and the joys and sorrows of tea-making.—L. S.—*Field*, August 18th.

THE SEASON'S CHINA TEAS.

As far as the present season has gone, those who have been engaged in China tea are probably fairly well satisfied with the results. The amount that has come forward is not excessive, and there can be no doubt the teas are better than for some seasons past. The preparation has evidently been of a more careful nature, and the leaf is more even and better twisted. The proportion of dust has, likewise, not been too preponderant. Teas that have been carefully bought and above medium grade have done very well; it is the commoner kinds, as during the last few seasons, which show the losses. These are aided, too, by such heavy auctions as took place on the 30th inst., when buyers could not have had time to properly taste all the samples, and consequently a languid interest in the sales encouraged the droop in prices for the commoner kinds, which had been apparent for the last two or three weeks. What the hurry is we cannot determine, seeing that with the stoppage of business at Shanghai for some period, consequent on the very arbitrary action of the Tea Guild as to fire insurance, must mean that the supplies coming forward are of a moderate nature. In this matter the Guild took steps to declare that the risk of fire should be borne by the presumed purchaser, from the time that the tea was delivered into his godown, and before it was weighed and approved of. This and one or two concomitant proposals not being immediately accepted by the foreign merchants, all business was stopped. Not only in tea, for it extended itself to most branches of trade other than tea. Subsequently the guild went to work in a more orthodox manner, and addressed a representation on the subject to the Chamber of Commerce. Any way this action has caused the shipment of tea from Shanghai to be suspended for some weeks, so that the apparent haste seems to be the more inexplicable. This, of course, is all second crop tea, and it is notorious the first crop was very short. At all events, as far as the present season is concerned, we must recognise that China teas show signs of much better preparation. The other fact that has been animadverted upon of late, weighs against them still, and presses heavily on them in their competition with teas grown in other countries. We refer, of course, to *levin* and export duties. With these charges handicapping them there seems no outlook for a recovery of the first place they held, though it is abused to suppose that and demand for them will altogether cease. There will always be a certain demand.—*L. and C. Express*, Aug. 31st.

COFFEE MIXTURES.—The trade in coffee mixtures seems to be dying out. In 1882-3, when the 3d and 1d labels were first issued, a revenue of £6,344 2s 2d was collected. The revenue has steadily decreased, and last year amounted only to £2,855 12s 8d.—*Chemist and Druggist*.

CEYLON TEA IN AUSTRALIA.

(By "A Struggler.")

As statements have been frequent in the *Observer* that it is difficult to spread the use of Ceylon tea in Australia, the experiences of one who has been struggling to earn a living in this direction dealing with consumers and his opinions as to the cause of this, together with his prognostications as to future prospects, are offered to you for what they are worth. It appears that the chief obstacle in the way is the indifference of the Australians, as a body, as to what tea they drink, being guided more by the brand or the name of the grocer who supplies them than by the quality or flavor of the tea. Sentiment is unknown, unless through the pocket, otherwise one would think that the strong feeling against the Chinese now so (barbarously) prevalent would lead them to try the products of the British settlement rather than that of what they designate the "yellow agency," but this feeling does not trouble them. It is enough that the tea of China is cheaper, and if an attempt is made to explain that the cheapness is only apparent, the reply would probably be that they know better, a weakness of the inhabitants being their own high estimate of their cuteness and a strong aversion to anything new. Travelers in attempting to push Ceylon tea frequently find a little amusement in the remarks of consumers, which somewhat tempers the disappointments met with; one having frequently been threatened with a prosecution for selling poisons, and being left to the tender mercies of the sanitary inspector, or the policeman; and the comparing it with senna and other such flavory herbs is of frequent occurrence. The tenant of one house may probably offer the remark that there is no flavor in the tea at all, whereas the next neighbour may venture the opinion that it is not tea at all, but some other very strong abomination. Among the minority who really go to the trouble to form any taste in the matter, a penchant for an exceedingly strong China orange pekoe prevails; the few, however, who, at the first, take to Ceylon fortunately remain constant to it, but it is uphill work to find out these few, as it is not in the nature of the people (as a rule) to go to the trouble of recommending to their friends an article they may like themselves. Notwithstanding so many disappointments amongst the consumers, the large importers are now however beginning to turn their attention to Ceylon, partly because they, as a rule, follow the London markets in these things, and partly because of the lower rates at which Ceylon can now be had through the marvellous increase of manufacture, comparing favourably with the prices at which they have been usually importing Indians; and they are beginning now to think them preferable to the rougher Indians generally used by them for blending. As the large houses are now beginning to take this in hand, the consumption will rapidly increase, not that the householders will value it on its own merits, but simply because it is imported and recommended by firms whose names are familiar to them.

Importers complain that they can never get consecutive shipments, even from the same estate, of one standard: if the Ceylon proprietors can undertake to ship tea of an equable quality and flavor to the colonies, there is no doubt that in the near future the demand will increase. So far the pioneers in Ceylon tea in these parts have met with scant encouragement, many having attempted to make a living out of it and failing given it up in despair, while to one and all it has been a struggle.

LEAF PLUCKING, TEA, &c.

As far as this season has gone, it is just about as bad as last season was a good one. A number of gardens are far behind in their estimates, and with but little chance now of making good the lost ground, no matter how favourable the remaining portion of our season may be. The short outturn without a rice in prices will just make all the difference between concerns paying a dividend or proclaiming a loss; this to the sorely tried shareholders of tea estates after being buoyed up by last season, will be, to say the least of it, very vexatious, and we will doubtless hear of wholesale changes in managements this coming cold season. This season we have had hail-storms with an excessive rainfall, and this has much to say to our short yield to date.

Besides, having suffered from hail-storms and an excessive rainfall we have suffered from red spider blight very severely, and this blight in itself is quite sufficient to ruin a season's prospects if it sets in badly. Those gardens that were not cut up with hail were unable to get away owing to the excessive rain and cold weather we experienced up till June; lowlying estates imperfectly drained, suffered through the soil being submerged; and all more or less from red spider. The season has so far been one of the very worst the tea industry has had to contend with for a long time, and more especially will it be felt when we were looking so expectantly forward for another bumper season, so that we might, on the top of last year, swamp the China teas out of the London market, and at the same time make it hot for our friends in Ceylon.* Had we been able to do this, there is not a shadow of a doubt that with the ascendency we had once got of the London market, we would have been in a position to have held our own against all comers, but I fear, owing to a short crop, we will lose some ground, which at such a critical time as this is very disappointing. It will take another year or two before we hold the position which a bumper crop would have given us this year in the London market. We have been told that fine teas are what buyers are wanting this year, and so a rush has been made to satisfy the demand, with the result that our fine teas have exceeded the demand and are only now fetching the price of medium quality teas. In a former communication I said that only 25 per cent. of our teas should be of this very fine class, and explained my reasons for saying so. How many men have sacrificed medium quality tea for this fine tea this season, who if they had to do it again, would go in for it?

After bushes have been pruned, for the first flush leave four, the second two, and third one, leaves respectively, and toward the end of the season only the quarter leaflet which the coolies term the *jennum*. If any of my readers will look up "Johnson's Gardener Dictionary," or any other standard book on plant culture, they will find in what position leaves stand to the plant. Here is what "Johnson" says:—"Leaves are highly vascular organs in which are performed some of the most important functions of a plant. They are very general, but not absolutely necessary organs, since branches sometimes perform their offices. Such plants, however, as naturally possess them are destroyed or greatly injured by being deprived of them." Again, he says:—"The functions of leaves appear to be a combination of those of the lungs and stomachs of animals; they not only modify the food brought to them from the roots, so as to fit it for increasing the size of the parent plant, but they also absorb nourishment from the atmosphere," &c., &c. "The power of leaf to generate sap is in proportion to its area of surface, exposure to the light and congenial situation." My object in quoting Johnson is to show my readers also an authority, says on the subject, and so to add weight to my argument that all leaves should not be stripped off in pruning. N. B.—Ed.] and that the best means of getting quantity with medium quality is by sticking to the rule laid down by me for the leaving

* How kind and brotherly! What if Ceylon, with abundant yield and the absence of pest, makes it hot for the big brother!—E.

of four, two and one leaves in the first, second and third flushes. Owing to the visitation of red spider this season in most estates, one of the most injurious of all our pests, leaf has been checked in its growth, as this little creature so impregnates the leaf and exhausts it of all its sap, that the leaves so affected are unable to perform the functions required of them, and we thus get little or no leaf, and what we do get is the dwarfed crinkled leaf from which good teas cannot be made. The only way to overcome this is to cultivate the bushes and try to make growth, and though it is a trying time waiting till the bushes make a start, it is really the only safe and sure remedy we have, and far and away superior to the remedy gone in for by some men of plucking all the crinkled leaves down to *jennum*, as by this latter treatment the plants undergo a very severe shock, as it deprives them of their very lungs, and to my mind such treatment of a bush is quite as bad as the blight itself, if not worse. Now, another point I want to draw the attention of my readers to, is the difference of yield that exists between some districts that are very similarly situated as to soil and climate, and the vain and futile attempts made by men to get a similar yield without having studied how this can be got. Bushes to yield a large quantity of leaf per acre require first of all to be of a good *jat*, secondly to be treated so that the very most can be made out of them, and there is no use in thinking it can be got any other way legitimately. It can, of course, be got for about three years by systematically hard plucking the bushes, and this is but too often done and the garden suffers for it as do proprietors, who, from an excessive greed cry out for large dividends when their gardens for some cause or another, such as inferior *jat* of tea, want of cultivation, bad treatment extending over a series of years, or from exhaustion of the soil, as not in a position to yield well. We hear men say, we don't want big bushes, we want small broad plants. Their idea of what a small broad plant should be like, I hardly fancy they could describe if called upon to do so. I am quite sure no really good man would care to have big lanky plants, his object being to have a small or medium-sized plant, carrying breadth with it, as he is quite wide enough awake to know the position the leaves hold to a bush, as he is aware that it is not only from the roots a plant derives its food. Such a man will by careful pruning, and plucking, bring his bushes into shape, so that they may cover as large an area as possible. Plucking down to the *jennum* before the month of September, I consider hard on plants, and only permissible in exceptional cases, such as in plant that is to be pruned down to the stump the coming cold season, or on large indigenous bushes; the object in so plucking being to get finer leaf. No one is fool enough to imagine, I hope, that this style of plucking gives quantity. In the above cases it is allowable for the reasons laid down by me, but to do so on small bushes is nothing more than suicidal; the large indigenous bush covers a much lesser area of ground than the medium-sized plant, consequently has more leaves or lungs on it, and, as a rule, this class of plant is only cut over the top in the pruning season, and not cleaned out much, so that its branches, large and small, combined with the leaves, help to keep the plant healthy. Large bushes are best adapted for fine leaf plucking, and small bushes for quantity; at first this may seem absurd, but it is the case nevertheless, for in the former the leaf is nipped off every fifth day when very small, and in the other the leaf is allowed to grow forming wood as it grows, and plucked from the eighth to tenth day, and such leaf is bound to weigh more than fine.

In conclusion, let me say that more harm has been done with fine plucking to estates, than by coarse plucking, and this fine plucking originated in this district with exports who came up to teach men the work they were paid for doing, and to make fine teas. These men insisted on fine leaf apart from quantity and so gardens were sacrificed for a season or two's crops. However, that was of no concern to such men, who were, so to speak, only time bargainers.—CACHARI.—*Indian Planter's Gazette*.

THE CHINA AND INDIAN TEA GROWERS.

The following, from the *Calcutta Englishman*, is a report of the minutes of a meeting of the committee appointed to inquire into the state of the Tea trade at Canton:—

Present:—Messrs. E. DEACON (in the chair), K. D. ADAMS, E. W. MITCHELL, and R. B. ALLEN (secretary to the meeting). Mr. F. O. DEACON was unavoidably absent. The Chairman having read the notice convening the meeting, invited the members of the committee to give their views on the subject under consideration. A prolonged discussion then ensued, and it was finally decided to put the following on record as being some of the points worthy of the consideration of the Chinese authorities, unless the Tea trade at Canton is to be seriously crippled, if not altogether annihilated, by the yearly increasing competition with India:—

SECTION I.—Canton Scented Caper.

This description of Tea, of which the bulk of the Canton export consists, competes more keenly with Indian kinds than any other class of China Teas, being especially useful for mixing purposes. The competition with India is now, however growing so severe, and home prices have reached so low a range, that unless some steps are shortly taken to relieve the produce of the excessive burdens of *likin* and export duty, a time must arrive when scented Tea will cease to be an article of consumption altogether. As regards quality, the districts from which the best descriptions of leaf arrive, being the most remote from Canton, suffer most heavily from inland taxation; and this induces native merchants to admit inferior leaf grown nearer to Canton, and suffering in consequence lighter dues. One of the greatest complaints, however, that buyers have to make is in respect to the large proportion of dust found in the Teas. The dust should, if possible, not be sent to Canton from the districts at all, as the Peking dues have to be paid on it as well as on the whole leaf; and this, of course, increases the ultimate cost of the Tea. This complaint is especially to be made about leaf arriving from the Loting and Hoyune districts.

SECTION II.—Canton Scented Orange Pekoe.

It may almost be said that this class (both the long and short leaf descriptions) has already been beaten out of the field by the success of Indian Teas; this is amply proved by the significant fact that, during the past ten years, the export from Canton has fallen from 3,870,000 lbs. to 1,100,000 lbs. This decrease in export continues year by year; and it now seems impossible that this class of Tea can regain its lost positions on the London markets.

SECTION III.—Cingous.

Of this kind, the best Teas arrive from the Taysan districts; and, as a rule, there is a steady market for these in London. The only suggestion that might be made is that better quality would be obtained if growers were contented with fewer pickings during the year. Experience has shown that Teas plucked in the months of August and September are deficient in every quality except "make," and the picking of the leaf in these months affects these supply as well as the quality of the autumn crop, which is the best produced from the district.

SECTION IV.—Weights.

It is worthy of remark that Teas shipped from Canton waters invariably lose in weight on the homeward voyage, where as those shipped from Foochow and the northern ports always show a distinct gain. The remedy of this is in the hands of the Imperial Maritime Customs, for native packers are prepared to allow an extra $\frac{1}{4}$ lb per box, provided no export duty is charged on it—a concession which the Imperial Maritime Customs will not grant.

SECTION V.—General.

The steady fall in exchange during late years has been of material assistance to the China grower, for it has enabled tea shippers to lay down their purchases in London at lower sterling prices year by year, while paying almost the same tael prices to the Chinese as formerly. The native grower must be looked to for any improvement in manufacture or production; and

as long as he feels no necessity for such improvement, it need not be expected. The members of the committee have read with much interest the correspondence which has already been published by the Shanghai and Foochow Chambers of Commerce relating to the decline of the China Tea trade, and they heartily concur in the opinions expressed by these bodies, and consider that the only real remedy for preventing the total extinction of the trade is the abolition of all *likin* and export duties, so that the China article may be on the same footing as the Indian, Ceylon, and Java, all of which are free from tax.—*Produce Markets' Review*.

PLANTING IN DELI.

(Translated for the *Straits Times*.)

Old experienced hands have a good time of it in Deli, now that estates in the neighbourhood spring up like mushrooms. Their owners keep a lookout for any Deli planters inclined to undertake the management of these new ventures. But, unhappily, the needful discrimination in the choice of managers seems often to be lacking. Evidently, in Java and Holland, where reside the moving spirits of these enterprises, the requirements that go to make an efficient manager are misunderstood. The opinion appears to be that all will go well with tobacco growing, provided there be liberal supplies of men and money. The local *Courant* enumerates the qualifications that characterise a good manager:—four years' experience at least in field labour and tobacco curing, a practised eye in judging land, some skill in planting matters, practical business knowledge, and sufficient tact and discretion to get along with Chinese labourers. Any one equipped with these qualifications has every chance of turning out to be a good planter, as well as an efficient manager. But people must not run away with the idea that all persons who call themselves managers in Deli possess these qualifications. The peculiar qualities that at once mark them out do not, in all cases, implant themselves in every one who has the good luck to stand at the head of an estate. Many never get them at all. Those who do, require more than four years' experience to qualify themselves. Too many never succeed in getting hold of the practised eye and the lucky hand, which alone can bring planting operations to a profitable conclusion. These are mostly inborn qualities, which meeting with a favourable environment in one's early years blossom in due time. Persons brought up as traders, officials, or soldiers can never acquire them.

The Planters' Association in Deli have taken steps to further the direct immigration thither of coolies from China. The long established system of engaging them through brokers in the Straits Settlements had resulted in raising the price of coolies intolerably high to the planters. The coolies, too, fared ill owing the lion's share of the advances they got falling into the hands of the brokers. The Planters' Association have established an immigration bureau at Medan, at which employers will be bound to engage coolies. The members of the Association have bound themselves to turn the bureau to account in recruiting labourers. It all depends now on how far they are prepared to act on the principle that union and strength must go together.

Siak has come, of late into prominence as a field for tobacco growing. The Sultan of the country does his best to encourage plantation enterprise there. The first planter from Deli who tried his luck in the new land of promise, grew tobacco which experts found no difficulty in pronouncing to be as good as the best Deli kind in the market. The natural consequence is a rush for planting concessions in Siak. The soil in Siak is said to be quite equal to that of Deli. The burning quali-

ties of the Siak tobacco turn out to be particularly good. It burns away steadily, and leaves clean white ashes. The rainfall, an important factor in that kind cultivation, is all that can be desired. The nearness of Siak to Singapore is another point in its favour.

DRUG TRADE REPORT.

LONDON, Sept. 6th.

ANNATTO.—Some Para Roll annatto which has been repeatedly offered for sale is now obtainable at 11d per lb. for fair red. Ceylon Seeds and Paste very neglected, and offering in large quantities. In Liverpool there has been a better demand for Guadeloupe annatto, and 25 casks TG brand are reported to have sold at 2d to 2½d per lb.

CALUMBA in good demand and selling at much better rates than were recently obtainable in public sale. Of 216 bags about one half was disposed of, realising 14s 6d to 15s 6d for yellowish mixed, dusty and wormy root, 12s for a dark mixed and dusty lot, and 5s for common dark and mouldy.

CINCHONA.—The assortment offered at to day's auctions was rather small, and very little of it found buyers. Some good bold silvery Bolivian Calisaya quill, said to contain over 5 per cent, of quinine sulphate, was bought in at 1s 2d per lb 10d being solicited, and one case very fine mossy red Madras quill at 3s per lb. nominally. Up to the present 2,696 packages are announced for sale at Tuesday's auctions, including 1,132 Ceylon, 442 Indian, 158 Java, and 964 South American bark. The exports from Ceylon between October 1st and August 2nd have been as follows:—1887-88, 9,978,480 lbs; 1886-7, 12,380,891 lbs; 1885-6, 13,717,867 lbs; 1884-5, 9,642,291 lb. The following are the official figures relating to the exports of cinchona bark from Java during the last five years:—

From	upto	Private	Govern-	Total
1st July	30th June	lb.	ment	lb.
1887	1888...	3,124,924	617,101	3,742,025
86	87...	1,569,842	660,433	2,230,275
85	86...	1,073,889	457,267	1,531,156
84	85...	776,510	419,160	1,195,670
83	84...	663,623	490,911	1,154,534

COCA LEAVES.—There is very little doing on our market, and only one bale broken but good pale Truxillo leaves was offered at the auctions, 1s 3d per lb. being mentioned as the price.

OILS (ESSENTIAL).—The shipments of cinnamon bark and leaf oils from Ceylon have assumed very large proportions indeed lately, and are now given as follows:—October 1st, 1887, to August 2nd, 1888, 132,505 oz.; 1886-87, 54,501 oz.; 1885-86, 89,248 oz. At the auctions only 3 cases of ordinary quality were offered, and for these 9½d. per oz was refused. The following are the shipments of citronella oil from Ceylon in the periods between October 1st and August 2nd:—1887-88, 8,833,177 oz.; 1886-87, 7,749,026 oz.; 1885-86, 5,165,430 oz. On our market the article remains in an extremely neglected state at ¾d to ¾d per oz. for native brands on the spot.

QUININE.—A much better feeling has set in since last week, and a large business has been transacted at gradually hardening prices. The English makers have made no alterations in their official quotations, but we hear that some of Whiffen's quinine sold in bulk today at 1s 5d. on the spot, and the makers ask a higher price. The German manufacturers have sold, it is said, up to 1s 5d. per oz. and now quote at 1s 5d. to 1s 5½d., the Ameribush factory not naming a price at all. At the end of last week it was reported that one of the German manufacturers A. Schott had made a contract with the Russian Government for 100,000 oz. at 1s 3d. per oz which is said to be the lowest price ever accepted for so large a quantity of first-hand quinine. *Chemist and Druggist* Sept. 8th.

Correspondence.

To the Editor.

ENEMIES OF THE COCONUT.

Hanwell, 20th Sept. 1888.

DEAR SIR,—Herewith I send you in a sealed bottle ½ a doz. insects found on my estate, feeding on coconut plants. They gradually consume all the leaves of the plant, leaving only the stalk and the eakies; eventually the plant dies or else its growth is retarded for some years. May I therefore beg you to let me know what the insects are and the best means of destroying them and preventing their attack—I am, yours faithfully,

G. E. AMERESEKERE.

[‘Locust,’ *Phymatous punctatus* (?) For description and details see ‘The Coffee Tree and its Enemies,’ Nietner, also Kirby and Spence, ‘Introduction to Entomology.’ I know of no other method of destroying them than to put a force of coolies on to collect them in sacks.—A. P. G.]

ENEMY TO THE CINNAMON BUSH.

DEAR SIR,—Have you ever witnessed an insect of the accompanying sample? They have been a cause of great distraction to my cinnamon plantation. They eat up the leaves as per sample and the tender tops and buds of the plants, owing to which the bark cannot be peeled. The insect you will find of a lark colour within the whitish case hanging by the leaves. Will you or one of your many subscribers kindly let me know through the medium of your columns some remedy for the destruction of these insects?

A YOUNG PLANTER.

[Mr. A. P. Green is good enough to tell us that the offender is ‘*Metisor planta*, Walker; fam. Psychidae.—’ This is the larva of a little moth, found on most trees and shrubs in the neighbourhood of cultivated districts. It constructs a portable silken case, which is more or less covered with pieces of stems or leaves of the food plant, in which the larva lives and undergoes its transformation. The female is wingless, and passes its existence in the larval case. There are several species of this family, most of them larger than the one sent by your correspondent. Tennent, in his Natural History, says:—‘The Sinhalese call these larval cases *Imakhatia*, or ‘billets of firewood’ and regards the inmates as human beings, who, as a punishment for stealing wood in some former state of existence, have been condemned to undergo a metempsychosis under the form of those insects.’ I really cannot suggest any remedy for their destruction, never having before heard of their being so numerous as to cause serious damage. Washing the trees with lime water or syringing with soft soap and tobacco water might induce them to depart, but I cannot give any authority.”]

COTTON-GROWING AMONG TEA.—One slip has to be corrected in our remarks on Mr. Blackett's experiment: the soil was not forked all over (a work that could scarcely be done for R2 an acre!) but merely stirred with a fork at the point where the cotton seed was placed; forking in this way taking the place of holing.

COTTON GROWING ought really to be tried very freely by planters in our lowcountry in view of the cheapness of the experiment. Mr. Blackett found that a hundredweight of seed sufficed for 100 acres, and that altogether the expense of the seed in the ground—or rather above, for three days saw it up,—was only R2 an acre. An advertisement elsewhere shows that there are three varieties of seed now available in Colombo, and it would be interesting to try all these on one place to see which was most suitable and profitable. Messrs. Dalry, Butler & Co have already distributed a good deal of seed, but all ought to be out before the monsoon.

FORESTRY ON THE ANDAMANS.

Mr. Carter's report on Forestry on the Andamans is said in the Government of India orders to be the first clearly written one received, enabling Government to follow the operations in the department.

As the Forest Act has not yet been extended to these islands, strictly speaking there are no forest reserves, but practically the whole area not actually cleared is reserved, and the forests are naturally protected from fires and gazing, while the habits of the aborigines, and the control exercised over the convicts, prevent forest offences.

The chief attention of the forest officer is therefore directed to profitable exploitation chiefly of padouk (*Pterocarpus indica*), and to the reproduction of this species in the forests.

Mr. Carter's remarks on this point deserve reproduction, and are as follows:—

"All efforts to encourage natural reproduction would naturally be directed towards padouk, the most valuable species in the forest; little experience has as yet been gained, and what is known offers little encouragement. The padouk trees in the forest are of large size and great age, so that not less than one-half are hollow and useless. There is no gradation of age classes, so far as padouk is concerned. The existing trees are probably 300 years old and for the past three centuries no natural reproduction of padouk has taken place. Other species have taken possession of the blanks which have been caused by fallen trees. These species must have been for the greater part shade enduring trees previously existing in the undergrowth and to a less extent seedlings of species with very rapid growth, which were able to get their crowns through the advance growth before it formed a canopy. Only in this way can the prevalence of such shade-avoiding trees as *Bombax* and *Paysonia* be accounted for, the shade-enduring advance growth has in many cases been *Doispyros* and *Murroya exotica*. The system of selection felling, without special operations to encourage a desired species must result in a forest consisting of trees capable of enduring dense shade, interspersed with trees (not necessarily shade-enduring) of very rapid growth. To neither of these classes does padouk belong. It cannot endure dense shade, or it would be found among the undergrowth in the forest. The shade given by it is not dense, for in the young plantation of padouk, although its canopy is complete, the ground is covered with a growth of low grass. It is true that this grass is of a shade-enduring kind, but it is entirely absent from the adjacent plantation, in which teak is the principal species. Nor is padouk of rapid growth when very young. When five years old it is scarcely more than half the height of a teak tree of the same age, although it is very probable that at the age of ten years and afterwards its growth would rival that of teak. The natural reproduction of padouk, therefore, must entail a considerable expenditure in clearing the ground to enable the seedlings to establish themselves, and in weeding out other species until the young padouk is out of danger, probably until the age of ten years."

We read further on the report that the teak planted in 1883 at Goplakabang are as vigorous as any plantation in Burmah, and the mixture with padouk will be favourable. Mr. Carter considers this plantation as the beau-ideal of what a teak plantation should be, and that there is probably nothing finer of its kind in India. Older teak plantations at Port Blair have not proved successful, but the plants were too far apart, sometimes at distances of 30 feet, and cattle were tethered under the trees, which growing without any undergrowth, have naturally not developed straight boles.

There can be doubt, as is remarked in the Government review, that teak forests in the Andamans would probably be the most valuable in the world, on account of the facility of transport, and we are glad to hear that extensions of these plantations are to be pushed on vigorously and also that valuable species of bamboos, as *Deodrocalamus Brandisi* are being introduced.

During the year, girdling was stopped, as there was a large balance of girdled trees in the forest, 4,158 trees yielding 7,173 logs, were felled, about one-third of

which were padouk. 5,076 logs were delivered at forest depôts, 3,375 to sale depôts, at which the following were the principal transactions:—

"Two-thousand-three-hundred-and-eighty telegraph posts sold for R13,265-11-5, after deducting shipping charges and commission, being R5-9-0 per post, and R75-14-6. On those delivered by contractors at R3 per post, the net profit was R2-9-0 per post, or R38-6-6 per ton. Twenty-five were lost in shipping and 100 rejections are lying in Calcutta, which will further reduce the net profit.

"Sixty one padouk Squares sold in London, Hamburg, and Havre, the London price being £13 per ton; and after deducting charges, the net rate was R56 12-4 per ton.

"Six hundred and one padouk planks sold in London for £10 per ton, yielding after deduction of charges R72-10-6 per ton. These were delivered by contractors at R25 per ton, and the net profit was therefore R47-10-6 per ton.

"Three-thousand-four-hundred and forty-one tea-boxes sold for R2,264-3-3, or R43-14-0 per ton. These were of Toungbeing, Tuitmin, and Simal."

Mr. Carter has calculated that the cost of timber delivered at Port Blair is R14-2 per ton, and at Shoal Bay R22-4 per ton.

From the latter depot, timber has to be shipped to Europe, and we read as follows regarding the proposed shipments to London of padouk timber:—

"Although it had been urged that a ship carrying 600 to 700 tons of coal should be sent from England under contract to take a cargo of timber back, a ship carrying 1,700 tons of coal was sent without any arrangement as to the timber. Only 670 tons of timber were ready to be loaded and the master of the ship refused to take these on reasonable terms. No ship suitable to carry the timber could be obtained in Calcutta, and the agents are now arranging for a ship at home at a freight of £2 per ton. Another year will therefore elapse before it can be ascertained whether any considerable trade can be done in padouk timber from the Andamans."

Mr. Carter's remarks regarding elephants will be useful where these animals are used for dragging—

"The number of elephants at the commencement of the year was 27 in addition to one calf, and at its close 20 and one calf. Seven elephants died during the year. In December the custom of giving grain rations to the elephants was resumed. For elephants working every day unless they are sick, grain rations are a necessity and not a luxury. The outturn of timber is entirely dependent on the number of elephants available for dragging. The number now on hand are only just sufficient to drag the logs needed for local consumption and even to do this they are over-worked. If, therefore, it is found that an export trade in padouk can be done on a larger scale, more capital must be invested in elephants or in a portable tramway. The latter is probably more advisable, for casualities among the elephants have been numerous during the past two years, and they are here peculiarly liable to a disease of the feet. Two of the present elephants have been thus incapacitated for work for six months, and it seems even doubtful if they will recover."

The surplus of the year's transactions was R5,580, besides a valuable cargo of timber being stored at Shoal Bay, and a surplus of R7,300 for timber works by district officers.

Surely it might be found practicable to have one account for all the timber works in the Andamans.—*Indian Forester.*

COCONUT REFUSE.—Coconut refuse is coming under notice for economic purposes as top dressing. Forestry experience in India, shows that coconut fibre answers admirably in that line. It stands heat and moisture almost as well as loam and has the advantage of freedom from offensive odour. It decomposes very slowly, and at length becomes reduced to a fine mould to which the roots of trees take kindly.—*Indian Agriculturist.*

JOHORE.

Shortly after his late visit to this country the Sultan of Johore established a new order of knighthood in his dominions called the Order of the Crown of Johore. The persons upon whom this honour is conferred bear the title of "Dato," equivalent to "Chief" or "Headman," and ranking in Johore with the "Sir" borne before the names of English knights. This title was given to Mr. James Meldrum, the first British subject who settled in the Sultan's territory; and the only other British recipients of the honour are the Duke of Sutherland and Prince Bernhard of Saxe-Weimar, both of whom visited the Sultan at Johore in the early part of this year. Dato James Meldrum is at present in this country as the Sultan's Commissioner to the Glasgow Exhibition, where there is a fine display of the produce of the Sultanate; and he gives a most interesting account not only of the resources of his adopted country, but of the future he believes to be in store for it, and of the important part it will fill in the development of the Eastern Archipelago as a producer of commodities, as a market for English manufactures, and as an essential portion of the great overland trade-route which must eventually be established between England, India, and Australasia.

Johore itself is situated at the southern extremity of the Malay peninsula, immediately opposite the island of Singapore, from which it is separated only by a narrow strait of half a mile in width. The Sultan is an educated and enlightened man, who has travelled much in Europe, speaks English well, is practically under the protection of the British Government, and is anxious for nothing so much as the industrial development of his country. The native race is, of course, Malay; but the Chinese immigrants form the bulk of the population. The Government is administered largely with the aid of Englishmen, and life and property are as secure as in any part of the East. The climate is extremely even, foliage is perennial, and there is an abundant but not excessive rainfall. As the general features of Johore are those of the entire peninsula, it will be convenient to consider the facts here stated as having that wider application. Iron ores are everywhere found, and in the south they exist in such profusion that at one time the roads of Singapore were macadamized with ore containing nearly 60 per cent. of pure metal. The whole length and breadth of the peninsula is said to abound in tin, gold, silver, copper, and arsenic have also been found in such quantities as to suggest the likelihood that it would be profitable to work them. The greater part of the surface of the peninsula is covered by immense forests of the finest timber. The export of timber is indeed one of the principal features of its trade, especially at Johore, where Mr. Meldrum has established the largest saw-mills in the East. To develop this trade, however, a railway is necessary, as the forests nearest to the capital and along the sea and river shores are being rapidly cleared away. For tropical agriculture the soil and climate are admirably suited. Pepper and spices, gambier, indigo, cotton, tobacco, tea, tapioca, coffee, sugar, and other produce are easily grown, although neither the plough nor the barrow nor any other agricultural helps are in general use; the hoe being the only implement of husbandry employed by the Chinese or Malays. Two and a-half acres are the most that a Chinaman cultivates in the year, and even this little is only obtained by hard driving if the man is working on monthly wages for a European. English capital, intelligence, and supervision would speedily alter this state of things, and planting in the Malay Peninsula would then in all probability be as profitable as in Ceylon. Concurrently with the development of the natural resources of the country it would be opened up as a market for British and Indian manufactures; and then, finally, would come its inclusion in the great highway of which it may already be said to be the last unexplored and unsurveyed section. Nowhere in the whole world not even in Africa—is there to be found so promising a field for new enter-

prises; and yet the most essential part of it, the Malay peninsula, has been known to us for nearly 300 years as well as we know it to-day.—*St. James's Gazette.*

A CURE FOR DYSENTERY.—Says Dr. Taylor of "Science Gossip" in the *Australasian*:—For some time past naphthaline has been a course of some trouble to gas companies generally. Now it appears as if, like all other "waste substances"—which are only "waste" because we don't know what to do with them—naphthaline will come into vogue for special as well as general uses. Medical men have discovered that it is a valuable drug in cases of dysentery, summer diarrhoea, and other intestinal disorders. Injections of it have proved valuable in cases of dysentery.

PLANTING IN JAVA.—From the Java papers we gather the following:—About the coffee culture at Java no cheering news can be gathered anywhere. For generations experiment has shown an abundant coffee year immediately following an occasional bad one. Now in 1887 the total coffee product in Java is reported to have been only 280,000 piculs, which is the lowest that can be found even over the last half century. The year 1888, instead of making up for it by a product of over one million piculs, as has happened several times, is reported to offer hardly any better prospects than the last. This comes very heavy; principally upon the native coffee planters, who are paid by the monopolistic Government for their labour relative to the amount of produce. The report says that during last year four million guilders were paid to native coffee planters for labour, the yearly average payment for that culture being about 14 millions. It is stated that during the last three or four years, the number of coffee trees at Java had actually been reduced by about 100 million trees, but as this would come to about 40 per cent of the total amount, and as sufficient reason for this does not appear, there is some difficulty in believing it. —Before the Resident's Court of the East Coast of Sumatra at Medan, Deli, a case was brought against the "Amsterdam Deli Company" and among the charges brought against the defendants it appears that they, as employers, had not offered to eight Boyanese Coolies, engaged at Singapore, discharge tickets at the end of their engagements and also that they had engaged and actually put to work on their plantations the eight Boyanese coolies, being foreigners, without written agreement. The Resident, sitting as Judge after hearing both parties, dismissed the case, but the Government Attorney, who had brought the charge, has entered protest against the judgment.—*S. F. Press.*

DISTRIBUTION OF CEYLON EXPORTS.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. III.]

COLOMBO, NOVEMBER 1ST, 1888.

[No. 5.]

CLOSE OF COMMERCIAL EXPORT SEASON, 1887-8.

See Chamber of Commerce Export and Distribution Tables on separate sheet.

We are enabled in the present issue to include the final tabular statement of the Chamber of Commerce for the season 1887-88, which reaches us, however, only a few hours before we go to press, and we can therefore only offer a hurried review of the same. The aggregate totals of our export trade in the main staples included in the Chamber's statement must, on the whole, be considered satisfactory. The volume of trade has kept up and developed even beyond expectations if the total result is kept in view. Of course poor old coffee has further shrunk, but tea has come to the front in actual shipments, and more particularly in the "promise and potency" of good things to come, in a way to more than make compensation. Cinchona as well as Cinnamon Barks have, in the opinion of most people, been shipped to an over-liberal extent. The trade in the various products of the Coconut palm is increasing steadily, a most satisfactory feature; while minor estate and low-country exports—cocoa, cardamoms, plumbago, timber, essential oils, keep well to the front.

We shall not be in a position to forecast the probable exports of each article for season 1888-9, with the care which we should desire, for some weeks to come. But it will be observed that in discussing each product separately, and very briefly, we add a *pro tem.* estimate of what may possibly be looked for during the current season in the export of each.

TEA.

The season's exports close at 20,755,779 lb., while the most generally accepted estimate—that of Mr. H. K. Rutherford—was 22,300,000 lb., or 1,544,201 lb. above the result; but it is quite reasonable that two factors that neither Mr. Rutherford nor anyone else could have foreseen account to a large extent, if not altogether, for this deficiency. One of these more immediately applying to the scarcity and dearness of freight to London which has prevailed during most of September, so undoubtedly delaying the shipment of a good deal of tea lying in Colombo ready

for despatch; the other factor was the quite exceptional drought which followed the burst of the south-west monsoon and has prevailed through August and most of September. This drought, while suiting some of the higher districts, has diminished the yield over a larger extent of lowcountry in the Kelani Valley and Kalutara districts especially. Altogether, therefore, we consider that Mr. Rutherford's estimate for 1887-8 may be regarded as a reliable one under normal circumstances, though the lesson of course may be to make more allowance in future for the great likelihood of some one abnormal circumstance turning up at one time or another, during the twelve months. Looking at the development of our tea industry for ten years back as given in the table, no one can feel disappointment. It is little less than marvellous that the industry represented by 81,595 lb. in season 1878-79 should have attained to 1,522,882 lb. five years later and to 20½ million lb. within the decade. The last-mentioned export shows an increase of over 66 per cent on that for the previous season 1886-7. It is a matter of regret perhaps that the proportion of our teas passed through the Colombo sales does not keep pace with our increased export. The total so disposed of was only about 2½ million lb. or 13.40 per cent of the whole exports, showing no increase over the local sales in season 1886-7, when the proportion was 13.31 per cent, while in season 1885-6, as much as 17.67 per cent of the total shipped, was sold locally.

Special interest is taken in local sales, because the larger proportion of tea therein bought is shipped to Australia and other countries than the United Kingdom, and of course the greater the quantity so diverted, the less pressure on the London market. As regards distribution, it is clearly the day of small things so far, in regard to our exports elsewhere than to the United Kingdom, that is London, which got 20,109,521 lb. out of 20,755,779 lb., leaving only 646,258 lb. for Australia, Continent of Europe, America, &c., or only 3.11 per cent of the whole. Out of this Australia has taken 479,626 lb.; but we trust the day is near at hand when a few millions lb. will be shipped from Colombo to Melbourne, Sydney, Adelaide and New Zealand ports, every season.

THE LARGEST SHIPMENT OF TEA FROM CEYLON, since the export commenced, seems to have been the 410,527 lb. taken away by the "Paramatta" the other day. cargoes of several millions of pounds have gone from China, but these have been in special tea ships, an institution not available and scarcely likely to be available for us in Ceylon. But we may look forward to the time when half-a-million and even a million of pounds will go as cargo in one of the larger steamers.

The largest shipment in any one month so far from Ceylon—as may be seen from the tables we append—was 2,588,000 lb. in June 1888. It is clear that the busy shipping season from Ceylon (as from India generally) will lie between April and October, though there will always be an appreciable quantity (perhaps 33 per cent) of shipments distributed over the other six months.

As regards the future, Mr. Rutherford's estimate of Tea Exports for season 1888-89, as given in our "Handbook and Directory" page 46, is as follows:—

	1888,	1889.
	acres.	lb.
Tea 5 years old and upwards ...	30,000	at 340=10,200,000
4 to 5 years ...	39,000	300 11,700,000
3 to 4 " ...	48,000	200 9,600,000
2 to 3 " ...	38,000	80 3,040,000
Not in bearing ...	24,000	
Do. seed ...	3,000	
	182,000	= 34,540,000
Local consumption say		540,000

Probable export=34,000,000"

Considering that the tea short-shipped during the past season will tend to swell the current year's return, this estimate might be thought perfectly safe. But for the reasons given in a full discussion in our "Handbook" (to which we may refer at pages 45-47), we are inclined to take a lower figure. In this we are supported by an Estate Inspector of experience who writes:—

TEA.—I see I am 4,000,000 lb. below Mr. Rutherford. I certainly do not like to question his figures, but I am sure he is now putting too much (350 lb.) on the 5 years old tea and upwards, for much of the tea in old coffee land is not coming up to 200 lb. per acre. I thus put my figures:—

Above 5 ..	30,000	acres @ 300 lb.	= 9,000,000
4-5 ..	39,000	" @ 250 "	= 9,750,000
3-4 ..	48,000	" @ 180 "	= 8,640,000
2-3 ..	38,000	" @ 80 "	= 3,040,000
			30,430,000

or say 30,500,000 lb.

Of course much depends on the weather. The drought of 1887-88 has been trying on the low-country estates, but if we have a wet season in 1888-89, that will put down the high estates' average. Within the last year more of the high old coffee land put in tea is included in the bearing area than of lowcountry tea in virgin forest or *chena*, and so the arithmetical progressive arrangement of Mr. Rutherford is, in my humble opinion, at fault.

Our own estimate for season 1888-89—so far as we can judge at present—is 32,000,000 lb.; but this may be modified by the information we expect to collect before the end of October.

CINCHONA BARK.

Shipments of bark have kept up again much beyond expectation. Our estimate a year ago, however, of 11 million lb. was as wonderfully near the mark (11,704,932 lb.) as our estimate of 14 million lb., made in October 1886, came to the actual export for season 1886-7, namely 14,389,184 lb. Unfortunately the clamour was so great in planting circles about our over-estimating, that about the end of 1887 we reduced our estimate to ten million lb. Again, we are assured on all sides of the rapid disappearance of cinchona trees from many estates and even districts, and certainly our stock is much less than it was a year ago in actual available bark on trees. Still, we can see no good reason for putting our estimate for the actual shipments of cinchona bark during 1888-9 at less than 9,000,000 lb. On this point our planting critic writes:—

CINCHONA.—I think your 9,000,000 lb. are correct. There is a good deal of this product lying in snug corners, and there is no use keeping only 2 per cent bark to compete with the over 4 per cent Java bark which is now beginning to come forward.

COFFEE.

Poor old coffee is going rapidly to the wall: only 136,295 cwt. shipped for last season. The distinction of "native" coffee may as well be dropped now, with only 6,442 cwt. or about 5 per cent to come under this head in the past twelve months. We suppose there is less still to be so classified in the coming season, and therefore, as we say, the distinction might well be abandoned. We much fear the total of coffee for 1888-9 will not reach 100,000 cwt., and yet we hear of some good crops in unexpected quarters; but on the whole we suspect our planting friend draws a true picture:—

COFFEE.—Some people doubt the 50,000 cwt. being secured, but the old staple dies hard, so I say 80,000 cwt. Arabian and Liberian coffee. We shall be better able to judge a month hence from our district returns.

"COCOA" FROM THE CACAO TREE

is again a grievous disappointment as regards total results, and it will be impossible to say that this product is a success over any appreciable area of cultivation in Ceylon unless our shipments speedily improve; but instead of that our information at present would seem to show that our export for season 1888-9 cannot be expected to exceed that of 1886-7 or at most 18,000 cwt. Here is an uncourtesy opinion, still more adverse:—

CACAO figures are disappointing also. We end this season with barely 13,000 cwt., carrying us back to 1886-87 export. Well, we have had terribly dry weather to date, so it will take some time to recover the effect of this 18 months' drought; so I really don't see how we can export more than 15,000 cwt. during 1888-89, though there are believers in an estimate of 17,000 cwt. I fear Kurunegala will not help us much, and Matale has been frizzling on the same gridiron as Dumbura.

CARDAMOMS

have done fairly well with an export of 310,685 lb., but we suppose we cannot look for quite so much during the coming season with planting attention so largely given to tea. Our correspondent remarks:—

CARDAMOMS.—So much of the land under this product is being rooted out for tea, and so little fresh land planted, that I fear my estimate is correct,—250,000 lb. against, say, 310,000 lb. in 1887-88.

We now append some tables given in our Handbook and partly made up to date from the monthly Customs Accounts as far as time will permit:—

"It is of special interest to observe what are the busy and slack months in our tea shipping business at Colombo. It is impossible here to have, even for a month, an entirely close or holiday time as in China, Japan and India. January and February are the slackest months, and yet over 5 per cent of the total crop is shipped in each of these months, respectively. Indeed, if we take the quarters, the tea business here is found to be wonderfully spread over the year, thus:—1st quarter 18.03 per cent; 2nd quarter 31.14; 3rd quarter 26.70; 4th quarter 24.11. The six months from April to September inclusive, give nearly 58 against 42 per cent during October-March. But a better way to get at the busier period is to count from May. Thus May-June-July give 34.32 per cent of the year's exports, while if we add in August we get 43.13 per cent. The four months, May to August, may, therefore, be considered the busiest in Ceylon; due of course to the south-west

NATIVE EXPORT PRODUCTS.

We now turn to the Exports which are more especially the result of native industry, and first we have the pre-eminently important trade in the various products of the (to the Sinhalese) invaluable COCONUT PALM.

Under nearly every head, the export last year has been the highest on record. This is notably the case in respect of COCONUT OIL, POONAC, and COIR FIBRE; while in respect of COPRA, COIR YARN and ROPE the results are very high, although COCONUTS number far less than in the previous season.

Apart from the enormous local consumption in Ceylon of the products of this Palm, it is well to see at a glance the total exports:—

EXPORTS OF PRODUCE OF THE COCONUT PALM.

a. At prices given in middle of 1888. b No records previous.

The approximate value of our tea, 20½ million lb., exported in the past season, for purposes of comparison with the above, may be taken at 12 millions of rupees; about the same as that of coconut palm exports; though the total of plantation exports in tea, coffee, cocoa, cinchona bark and cardamoms would be probably double this. Again, tea is bound to go on increasing, while, with the present very prolonged drought, we fear the next crop of coconuts will be short over a large extent of country, so affecting the exports of season 1888-9.

MINOR EXPORTS.

we can only very briefly allude to. PLUMBAGO shows a very large export last season in 254,046 cwt. and there is no sign of abatement in this industry.—CINNAMON BARK, like cinchona, in the supply almost outstrips the demand, and we would fain see a much less export of "chips" especially, so as to make a better demand for the pure bark, than is indicated in our table, the return for 1887-8 being:—

- Bales .. 1,657,424 lb.
- Chips .. 496,887 lb.

Total 2,154,311 lb.

In respect of our export trade, in EBONY, SAPANWOOD, DEER HORNS, ORCHELLA WEED, KITUL FIBRE and CITRONELLA as well as CINNAMON OIL, we need only refer to the table to show that a steady and progressive trade had been done during 1887-8: in Essential Oils, the rapid increase in exports, season by season, being especially noteworthy, though this, we regret to think, has not been accompanied by a corresponding profit to the producers and manufacturers:

ANNUAL ADMINISTRATION REPORT OF THE GOVERNMENT BOTANICAL GARDENS AND PARKS, NILGIRIS.

By M. A. LAWSON, Esq., Government Botanist and Director of Government Cinchona Plantations, Nilgiris.

I. SEASON AND RAINFALL.—The rains began in February 1887, and good showers were experienced all through March, April, and May 1887, till the monsoon burst on the 10th June; and in consequence of this wetness of the season, the younger plantings came on very satisfactorily. During June, 9 inches of rain fell, and the weather continued to be wet till the 15th July, when a break occurred, that lasted almost without intermission, till the beginning of October, the rainfall for July, August, and September being only 4.08, 3.73, and 4.99 inches, respectively. The north-east monsoon broke with considerable violence on the 3rd October 1887, and the weather continued more wet than usual till the close of the year, the last week in the year being exceptionally so. The frost during January and February was of unusual severity and the damage done to the trees and shrubs, both at Ootacamund and at Sim's Park, was considerable. The frosts in the early part of January were the most destructive, as they occurred immediately after the heavy rain which fell during Christmas week and before the ground had dried and the plants had lost their succulency. Geraniums, Fuchsias, and many other hardy plants, where at all exposed, were killed outright, and considerable injury was done to vegetable gardens.

II. GENERAL CONDITIONS, &c.—(1) Ootacamund.—(a) Government Gardens.—Several alterations for the better have been made in these gardens. The *Lonicera* hedge at the entrance was much injured by grubs, and as it did not seem likely soon to recover, it was taken up and a new hedge of *Cupressus macrocarpa* planted in its stead. This resists the attacks of grub more than any other plant, and will in two or three years form a thick and ornamental fence. * * *

(c) Stonehouse Park.—The trees and shrubs planted out some years ago made a good growth. The broom which had spread out too far over the ground was partially dug up, and it will be still more confined during the present year. * * *

[Common broom is not, we presume, intended? Perhaps the broom grass. It is curious that while furze has become so thoroughly naturalized at Nuwara Eliya, broom has not yet succeeded in establishing itself.—Ed.]

(e) Crewe and Ottley Hall Estates and adjoining ground.—The frost again proved very destructive to the *Melanocorydon*s which were planted on these estates. The *Cupressus torulosa*, on the other hand, were uninjured, and have during the present spring grown considerably. The ground opposite Ottley Hall was sown with Australian oats. These came up and grew well, but unfortunately the entire crop was destroyed by the frost in the early part of January. * * *

(3) Barliya*—Experimental Garden.—The usual upkeep has been maintained in this garden; some thinning was done amongst the younger trees. The crop of *Mangosteens* and *Litchis* was a very poor one compared with that of the year before. The *Hevea Braziliensis* flowered for the first time this spring. The *Durian* is growing vigorously and seems to be quite at home.

III. HERBARIUM.—The botanical collections are in good order, and have been considerably increased during the past year. The rearrangement of the plants in the Madras Herbarium has been gone on with, but is not yet finished. The delay is due to the specimens of the later natural orders being very imperfectly or wrongly named. During the year a large number of economic and other plants have been referred for identification from Collectors and others, by the Board of Revenue, and from other sources. This identification of plants has indeed occupied a large amount of time.

A collection of about eight hundred species from the Madras Presidency was sent to the Botanical Gardens at Oxford and a much smaller collection of plants from the Nilgiris to the British Museum.

* Less than half the elevation of Ootacamund.—Ed.

IV. LIBRARY.—R729-5-9 were spent during the year on Botanical works; Dr. King presented a copy to the Library of his important monograph on the genus *Ficus*. Eight decades of Von Muellier's Iconographia of Australian species of *Acacia* were presented by the government of Victoria. Dr. Trimen has also given a copy of his Catalogue of plants—exotic and indigenous—growing in the Royal Gardens, Peradeniya. Mr. Thistelton Dyer, Director of the Royal Gardens at Kew, on behalf of the Bentham Trustees, has presented new numbers of the *Icones plantarum*; and also copies of the Kew Bulletin.

V. NOTES ON SOME OF THE MORE INTERESTING PLANTS WHICH HAVE BEEN INTRODUCED OR GROWN IN THE GARDENS DURING THE YEAR—(1) *Phoenix dactylifera* Date.—The seed of this palm, which was sent through Mr. Duthie, the superintendent of the Saharanpur Gardens, was completely destroyed by weevils, before it reached its destination. As it has already been stated in my report, there can be little doubt but that the date would grow well in many parts of Southern India.

(2) *Teff. Fragrostis Abyssinica*.—This grass seeded freely at Coonoor, and it is proposed to distribute the greater part of it to planters in the Wynnad

(3) *Vitis Ampelocissus Martini*, or the *Cochin-China tuberous-rooted vine*.—This vine is fruiting freely this year, and as the plant grows older, it seems likely that it will continue to yield an increasingly heavy crop every succeeding year.

(4) *Medicinal Rhubarb*.—Plants have been put down in the garden at the jail at Coimbatore, and others will be planted out shortly in the new garden at Gudalur.

(5) *Ipeacuanha*.—There are in stock altogether about four thousand plants, five hundred of which were planted out last year at Nilambur; out of these five hundred, three only have died, while the rest are vigorous growing plants, although they have been topped and the leaves stripped off them no less than three times during the last nine months. In accordance with the instructions issued in G. O., No. 2524, of 27th April 1888, Revenue, about two thousand well-rooted plants will be distributed, free of cost, to planters during the present season; the remainder will be removed for increasing still further the stock in hand. A set of instructions for the cultivation and propagation of the plant was printed and circulated last August. The reports on the growth of some few specimens, which were put out in the Wynnad last year, are most encouraging.

(6) *Narcissaria Alata*.—Mr. T. J. Ferguson of Calicut kindly procured 26 pounds of the air-dried stem and root of this plant and sent it for experimentation. This was handed over to Surge-General Bidie, who has reported upon it as follows:—

"It will be seen that, on the whole, the results of the trials of this indigenous remedy have been satisfactory, and such as to encourage its further use."

From this report it will be seen that it is probable that in mild cases of dysentery the *Narcissaria* may supplement the *Ipeacuanha*. Specimens of the *Narcissaria* have been planted at Nilambur, with the view of testing its rate of growth, in case further experiments should prove it to be a plant of high therapeutic value.

(7) *Jalap*.—Between five and six thousand tubers, of all sizes, have been put down in the Medicinal garden at Dolahetta, besides several thousands of cuttings; but it is not expected that any appreciable crop will be harvested before the winter of 1889 or 1890.

(8) *Rubber-planting of Trees*.—As a full report has so recently been made on these trees, it is only necessary to say that, while they grow vigorously, all attempts to extract the rubber, in anything like paying quantities, have up to the present moment completely failed. The *Cecropia*, *Cordia*, and *Bacca* all flower and fruit freely. The roots of the *Cecropia* swell out into large tuberous nodules, which contain an abundance of starch, similar to that of *Ipomoea*, but unlike the *Ipomoea*, the roots contain no poisonous principle, and are palatable, when either roasted or boiled.

(9) *Quillaja Saponaria*.—This tree flowered and fruited in the first time this spring.

(10) *Barilla*.—Several species, supposed to yield Barilla, have been experimented upon, especially the African *Oshosporium Montiflorum*, but none of them seem likely to be able to compete with the soda of commerce, the price of which is only £2-10-0 per ton.

(11) *Seakale*.—The plants which were raised from seed last year have grown so rapidly, that by next spring they will be large enough to furnish a considerable cutting.

(12) *Michelia Nilagirica*.—A quantity of bark was sent into the market in London under this name, but as it had evidently no chemical relationship with the *Michelia*, leaves of the trees, from which it was said to have been taken, were forwarded to me for identification; and which, upon examination, were found to be those of *Gadonia Ohina* and of *Coccolobum Wrightii*.

THE INDIARUBBER TRADE OF UPPER BURMAH.

Mr. Warry, of the British Consular Service in China, at present stationed as political officer at Bhamo, has made a report to the Chief Commissioner on the indiarubber trade of the Mogoung district. Rubber was first exported from Upper Burmah in 1870, and until 1873 the trade was free to all. Since the latter year, however, the forests have been worked under the monopoly system, five Chinese firms being the joint concessionaires, two supplying the money, and three superintending the work. The price ranged from £60,000 to £90,000 per annum, but in the present year the sale of the right produced a lakh of rupees. The forests occupy an extensive Kachin district north of Mogoung and stretching east across the Chinese border. The Kachins are exceedingly jealous of interference with their trees, and although at first they made the mistake of over-bleeding them, they are more careful now, and though the trees seen by Mr. Warry were covered with innumerable small incisions, even up to the tiny topmost branches, they were obviously not drained to the extent of half their power. Mogoung is the headquarters of the trade; four-fifths of the yearly supply is brought in there by Kachins in the employ of Chinese, the remaining fifth is purchased in the district by Chinese agents of the lessees. The practice is for the Chinese manager in Mogoung to make liberal advances to the Kachins to defray expenses during the collecting season; when the rubber is brought in, the refund is made by selling the rubber to the manager at half the market price. The travelling Chinese agents who also collect rubber, merely travel from place to place, buying such quantities as the Kachins offer, but as the latter have no standard weights they are usually cheated to the extent of about 70 per cent. The profit on this difference of weight more than pays the expenses of the agents. In most cases rubber is the subject of certain transit charges through the Kachin districts, tsawbas, or local chieftains, levying a certain toll—perhaps two or three balls out of a hundred. So long as these charges do not amount to 10 per cent, there is no complaint. Whatever the toll, the Chinese manager and Kachin owner bear the loss in equal shares; but the latter is amply compensated by being housed and fed at the expense of the Chinese during his stay in Mogoung. Last year a new district was opened, and a Chinese capitalist employed 200 Chinese and three managers to work the forests in the neighbourhood of the rubber trees. The local Kachins objected to the inroad and insisted on their right to the forests. A compromise was reached, 90 of the Chinese being sent to work the forests, the remainder consisting of rubber under Kachin supervision, to whom a percentage was to be paid, and 100 Kachins, all at the current rate, took the price of the rubber as usual—£2-10-0 per ton.

AGRICULTURE AND ITS IMPROVEMENT IN SOUTHERN INDIA.

[The following extracts from the lecture delivered in England by Mr. Robertson, for so long a period Superintendent of the Saidapett Farm, Madras, have a reflected interest for us in Ceylon. It will be seen that a better and less aquatic rice than that indigenous to India can be obtained from Madagascar, but that this and Carolina rice require deep ploughing; maize and sorghum ought to be profitable crops if properly attended to, and each can be sown in alternate rows with cotton, if the soil is rich; cotton will, we trust, yield larger crops than are obtained in India; while tobacco requires soils rich in carbonate of potash.—ED.]

CAROLINA RICE.

About 20 years ago, on the suggestion of Dr. Forbes Watson, F. R. S., attempts were made to introduce Carolina rice into South India. Dr. Forbes Watson pointed out the fact that Carolina rice in the European market usually sold for a price nearly twice as great as ordinary Madras rice. Through his agency a quantity of Carolina rice seed was obtained direct from the United States, and forwarded to Madras. The average temperature of the rice districts, of Madras in the cropping season does not differ greatly from that of the rice region, in South Carolina, at the time of year when the rice is cultivated. The seed was widely distributed in all the rice growing districts of the province, and it was sown ordinarily under the same conditions as the common rice. The cultivation was left entirely in the hands of the people willing to undertake the experiment, though papers containing suggestions for their guidance were printed in the vernacular and distributed with the seed. In a number of widely scattered places the new crop grew well, and yielded in some instances heavier crops than the common rice grown under similar conditions. But a wide experience showed that the seed belonged to a stage in agricultural progress that had no yet been reached in South India. The general results showed clearly that the slovenly treatment to which the common rice is generally exposed is much more pernicious in its effects in the case of Carolina rice. Crops of the common rice grew and gave fair results under conditions that proved disastrous in the case of the higher rice. The Carolina rice plant was found to have long roots that feed deep down into the soil, while the roots of the common rice spread over the soil and form into a network over the mud on which the crop grows. Ordinarily, in Madras the soil for rice is shallow tilled, and is worked, while under water, into a puddle. Under this treatment the under-soil becomes sour and unfitted for healthy root growth. A soil in this state would be utterly unfitted for the growth of a crop of Carolina rice, and yet, a fair crop of the common surface feeding rice might be produced on it. Further supplies of seed were obtained, and the experiments were repeated, but the general results were all similar. When the soil was deep and healthy, with fair under-drainage, and the irrigation water was used with care and judgment, good crops were produced; under the opposite conditions the crop generally failed. It is doubtful, however, whether if the cultivation was better, and the crop generally succeeded, the rice produced from the Carolina seed in Madras would sell for a much higher price than that for which ordinary Madras rice sells, unless the method of husking and preparing the rice for market was raised to the American standard. I sent a small consignment of Madras grown Carolina rice, prepared in the ordinary native method, to this country to test these questions and the price realised, though higher than that of any Madras rice sold at the time was considerably below that at which American Carolina rice was then selling. It being generally believed in the United States that Carolina rice was introduced from Madagascar. I obtained from that Island a number of samples of the varieties of rice generally cultivated, and among these was pleased to find one variety, known as Rajafatsky, that resembled somewhat Carolina rice, a resemblance I found much

closer when I saw the crops of the two kinds of rice growing. If this is not the variety of rice from which the Carolina originated, it is, nevertheless a variety well worthy of attention in South India; it possesses so many of the good points of the Carolina, while it has been grown under the same rude agriculture as prevails in South India. One of the chief points of importance common to both the Carolina and Madagascar rice plants is that they are much less aquatic in their habits than the ordinary rice, and consequently may be grown with an expenditure of much less irrigation water.

I may mention that among the samples of rice received from Madagascar there were some not unlike a few kinds of Madras rice. May it, therefore, not be possible that Madagascar obtained the rice plant from India, and that the so-called Carolina rice may be descended from Indian rice, its excellencies being due to good cultivation in a virgin soil, under a favourable climate.

MAIZE.

Maize was another cereal that engaged our attention at about the time we were introducing Carolina rice. Maize is almost unknown as a field crop in South India. A few different varieties were obtained from the Southern States of America, Egypt, Queensland, the Cape, and Queensland seed; it appeared to need no acclimatisation. Heavy yields of grain and straw were obtained from sowings of this seed. The straw proved to be especially rich in saccharine juices, I had some experiments made in extracting this juice, and in making jaggery (crude sugar) from it; following in this the usual native process. The results showed that from 100 pounds of fresh straw three pounds of jaggery could be made. This jaggery, on analysis, was found to contain 34.99 per cent of crystallisable, and 11.46 per cent of non-crystallisable, sugar. This maize was produced on a soil containing 90 per cent of sand: on a good soil the yield of saccharine juices in the straw would, of course, be much greater. The refuse straw, after being crushed in squeezing out the juice, formed excellent cattle food. The Maize crop may thus yield grain for the food of man and stock, a crude sugar and straw.

Very good results were obtained in growing maize along with cotton in alternate lines. It was found that the shelter the maize plants afforded the young cotton plants was very beneficial, while as the maize was removed before the cotton needed the whole of the land, the cotton crop suffered in no way. Ordinarily cotton occupies the land in Madras about nine or ten months, and maize about three months. Both crops being sown at one time, the maize crop was usually harvested when the cotton plants were just beginning to throw out their side branches, and needed the extra space. This combination of crops removes one objection usually made to cotton culture in South India where food for man and beast is so much needed, that it provides no food for man and but little food for stock.

Unfortunately, maize has made but little progress as a field crop owing chiefly to the inferior character of the cultivation generally adopted. A short time ago I saw a lot of cobs that had been received from one of the districts in which the crop has been persistently cultivated, and none of these weighed more than one-seventh of the weight of the average crop produced by the first sowings of the imported seed.

SUGAR SORGHUMS.

The sugar sorghums received a great amount of attention. *Sorghum vulgare* is extensively grown in South India. The area annually under this crop is over 31 million acres black seeded, yellow seeded, and white seeded, varieties are all grown. All give fair yields of grain, and of straw, but the straw generally contains no saccharine juice. As far as yet been ascertained, there are none of the sugar sorghums indigenous to South India. It was therefore considered desirable to introduce some of the sugar yielding varieties. Seed was obtained from China, from Queensland, from the Cape and from the Southern States of America. The varieties introduced were the *saccharatum* and the *kaffrarium*. Both grew well in all

parts of the province where they were tried, and the straw proved to be rich in saccharine juices. Average samples of the juice of the *saccharatum* was found to contain 10.50 per cent of crystallisable, and 1.79 per cent of non-crystallisable sugar. Ordinary sugar cane, I may remind you, contains about 15 per cent of crystallisable sugar and about half as much of the non-crystallisable.

Comparing ordinary sugar-cane with sugar sorghum, the former needs a rich deep soil which necessitates a large expenditure in preparing the land and providing the cane sets, &c., demands regular irrigation during its entire growth and occupies the land over twelve months. The sugar sorghum will yield fair crops on very ordinary soils, the seed is cheap and the land needs no expensive preparation, irrigation is unnecessary in ordinary seasons and the crop never occupies the land longer than from three to four months; while unlike the sugarcane, the sorghum will yield grain, a crude sugar, and a feeding straw.

The sugar of the juice of the ordinary *S. saccharatum* (the Chinese sugar-cane) always crystallised with difficulty, but that of the juice of a variety known as the Early Amber, and that of the juice of the *S. kaffiratum* we introduced from the United States usually crystallised freely, though as far as our experiments went in, neither case was this so readily or perfectly as in the case of the sugar of the ordinary sugar-cane juice. However, as far as regards the manufacture of jaggery, as large an output was obtained from sorghum juice as from sugar-cane juice.

All the ordinary cereals of South India received more or less attention, but I have not now time to refer to other cereals. I may just mention that nearly all these cereals yield small seeds with a considerable percentage of husk and usually contain but a small percentage of albuminous matter. The pulses are better as a rule but the area of land occupied by the pulses is small. This is much to be regretted, both on agricultural and physiological grounds, for cereals occupy far too much of the cultivated land, and pulse is so especially needful in the diet of a non-flesh-eating people such as live in South India.

COTTON.

In many respects the soil and the climate of the province are suited for cotton culture; indeed, there are vast areas of black soil specially fitted for the crop. But, while the average yield of cotton in Madras is only 70 pounds per acre, the average yield in the cotton States of America is over 300 pounds per acre, while American cotton usually sells here for from 25 to 50 per cent more money than Indian cotton.

The desirability of improving the quality and the yield per acre of the cotton crop has long been recognised and efforts have been made to introduce better varieties of the plant and improve the system of its cultivation. Much attention was given to this matter more than forty years ago, under the direction of an eminent botanist, Dr. Wright, but unfortunately he failed to recognise how intimately the question of cotton improvement is connected with that of agricultural improvement.

At Saidapet attention has been given chiefly to the introduction and distribution of good seed of the New Orleans, Yea Valley, Egyptian and one or two other well-known and appreciated varieties of cotton. New Orleans has been particularly successful, and by carefully selecting the seed for several years, the proportion of lint to seed has been greatly increased. The New Orleans has proved a heavy cropper and a hardy plant. The Yea Valley, a Peruvian variety obtained through the agency of Mr. Clements Markham, *c. n.*, was found to grow and thrive under good cultivation near the coast and to yield a long and valuable lint. A sample of this lint was valued in Liverpool at a higher price than any other kind of cotton on sale at the time from either India or Egypt, and as high as the best American cotton. The plant is unfortunately very liable to the attacks of a grub of a coleopteran insect. Egyptian cotton grows well in Madras, and some may be said regarding the Himgughtat, and one or two other kinds introduced from Bombay.

It has been clearly shown that there is no necessity to confine the culture of cotton to the black soils and better loams as is now the custom, for under good treatment poor sandy soils produce twice as heavy crops as the average crop yielded by much of the black soil region.

TOBACCO.

Tobacco is another crop to which much attention has been given; it is grown in all parts of the province but only in small plots. The total area of land usually cropped with it is only about 80,000 in a cultivated area of over 23,000,000 acres. The plant grows well in most parts of the province, and fair crops are raised, but generally the leaf is very inferior, from its poverty in mineral constituents, and the curing to which it is subjected is always unsatisfactory. The tobacco is almost unsaleable in this country, though the cheroots made at Trichinopoly meet with a certain amount of appreciation.

At my suggestion samples of tobacco from all the chief tobacco-growing districts were chemically examined. More than 50 samples were analysed. The investigation was confined to a determination of the percentages of nicotine and ash, the percentage of carbonate of potash in the ash leaf. The results of these investigations were valuable and suggestive. Nicotine varied from $1\frac{1}{2}$ to 7 per cent; the average was about 3 per cent. The percentage of nicotine determines what is usually called strength in tobacco; when there is over 4 per cent the tobacco is a strongly intoxicating one. Havana tobacco contains usually about 2 per cent. The percentage of ash averages about 20; in a few cases it was over 25, but there were others in which it was under 15. The greatest variations were in the percentages of carbonate of potash in the ash. In 39 of the 50 analyses made, the percentages of carbonate of potash was under 7; the majority being under 5; in some instances it was as low as 0.75. One sample, grown on the Nilgherry Hills, contained nearly 50 per cent. of carbonate of potash in the ash, and fine samples, grown in other thinly populated parts of the province, contained from 10 to 17 per cent. The potash in a tobacco influences greatly its burning, the larger the percentage the better it burns, and the whiter is the ash. Samples of tobacco produced in the United States contain frequently as much as 35 per cent of carbonate of potash in the ash. The low percentage of carbonate of potash generally found in the ashes of the tobacco of the older cultivated districts of Madras is a sure indication of the poverty of the soil in potash and this mineral is, it must be remembered, a food of the greatest value for nearly all kinds of cultivated plants.

The close connection between the percentage of carbonate of potash in the soil and in the ash of the tobacco grown on it, was shown in a remarkable manner in some tobacco experiments conducted at the Saidapet farm, the soil of which in 1868 contained but a trace of this mineral in 1871, the tobacco produced gave an ash containing on the average only 0.6 per cent. of carbonate of potash; in 1879 after seven more years of improved cultivation nine samples of tobacco produced in the same year were analysed. Of these, the ash of four samples was found to contain nearly five per cent of carbonate of potash and the ash of all the remainder contained each more than 3 per cent. In other words, the percentage of carbonate of potash was fully 12 times greater.

Tobacco seed of good varieties was obtained from the United States and other countries and distributed to cultivators along with suggestions for the more careful selection of soils and treatment of the crop. Special attention was devoted to the curing of the tobacco: the native system being a highly unsatisfactory one, chiefly in the excessive fermentation to which the leaf is exposed.

SMOKING SMOKE.

While efforts were made to introduce seed from other countries suited to the wants of the province, the fact was not overlooked that in some parts of the country superior varieties of indigo crops are grown, the seeds of which might with advantage be

introduced into the more backward or less favourably situated tracts of country. Attention was directed to this by means of agricultural shows and in other ways. There is nothing, I think, which more convincingly shows the apathy and want of enterprise among the agricultural population of South India, than the fact that the people over large tracts of country will persist in sowing year after year seed of inferior varieties of farm crops when frequently seed of better varieties could be got within a distance of 20 or 30 miles at an additional expense of only the carriage of the seed. It must, however, always be remembered that the native cultivator has to depend chiefly on his own resources in getting fresh seed as there are no field seedsmen in India as there are in Europe.—*Indian Agriculturist*.

AGRICULTURE IN CHINA.

There will be an immense field for business in the interior of China some day. The methods in vogue in all occupations are at present most primitive, and should afford scope for the introduction of modern tools and machinery. This is especially the case in connection with the cultivation of the soil, which is, of course, the chief occupation of the people. In this industry no progress has been made for centuries. There is great care, and minute details are attended to, but there is an extremely primitive knowledge of agricultural implements, and absolute ignorance of the principal of the rotation of crops, and the adaptation of soils to particular grains. The fields are cultivated with as much watchfulness and care as we bestow on gardens. When the crop is ripe it is gathered by hand, and not a straw or a leaf is overlooked or allowed to remain. In the vicinity of Peking, the principal crops, besides fruits and vegetables are wheat, barley, millet, beans, Indian corn, hemp, rice, cotton and some tobacco. The fruit and vegetables comprise almost all the kinds that are found in Western countries.

In irrigating his land the farmer uses many devices. Where running water is at hand he turns it to advantage by directing it over his fields in large channels, banked in with clay, and subdivided into smaller and smaller streamlets, until every part of the ground has been reached. If no running water is found, wells are dug and water is drawn up by hand and poured into the main ditches, which are subdivided into numerous smaller ones. Holes are dug in which rain water accumulates, which is baled out when needed. The raising of this water is in most cases, especially in the vicinity of Peking, done very laboriously by hand. Windmills, of which there is not one around Peking (if any where in China), might be used for this purpose with great increase of efficiency and saving of human labour.

Chinese agricultural implements are of the rudest character. They are, chiefly, the plough, the hoe, the harrow, the rake, and the stone roller. The plough is simply a broad blade fastened to a rough handle, guided by a man and drawn by teams of the most miscellaneous description; it cuts a furrow never more than six inches deep, and frequently only two or three. The teams are made up of horses, donkeys, mules, bullocks, and human beings, it being not unusual to see a man or boy, and any one or more of the animals above named drawing the same plough. Chinese farmers measure the depth of the furrow by the fingers, and frequently speak of ploughing only two or three fingers deep. The reason of this seems to lie in the difficulty of making a deeper furrow with their ploughs and not because they are unaware of the advantage of it. The hoe is a much more effective tool, and it is with this that they work between the furrows of grain after it has sprouted.

Foreign agricultural implements, especially ploughs, might be introduced with good effect among the Chinese, except that the price would deter all but very few from buying them. A Chinese plough can be bought for 8s. or 10s. and smaller tools in proportion. There are no great stores devoted to the sale of agricultural implements as with us, they being made by hand, either by a neighbouring blacksmith or by the

farmer himself, as occasion demands.—*British Trade Journal*. [Much that is true of China is true of India. Both have immense populations, chronically poor.—Ed.]

"DAMPING-OFF" OF SEEDLINGS.

The following extract is taken from an important and valuable series of articles from the pen of Professor Marshall Ward, now appearing in *Nature*, relating to the diseases of timber:—

"In the seed-beds, [Beech is specially alluded to] it is often first noticeable that patches of seedlings here and there begin to fall over, as if they had been bitten or cut where the young stem and root join at the surface of the ground: on pulling up one of the injured seedlings the 'collar,' or region common to stem and root will be found to be blackened, and either rotten or shrivelled, according to the dampness or dryness of the surface of the soil. Sometimes the whole of the young root will be rotting off before the first true leaves have emerged from between the cotyledons; in other cases the collar only is rotten or shrivelled and the weight of the parts above ground causes them to fall prostrate on the surface of the soil; in yet others the lower parts of the stem of the older seedling may be blackened, and dark flecks appear on the cotyledons and young leaves, which may also be turning brown and shrivelling up. If the weather is moist, *e. g.*, during rainy May or June, the disease may be observed spreading rapidly from a given centre or centres, in ever-widening circles. It has also been noticed that if a moving body passes across a diseased patch into the neighbouring healthy seedlings, the disease in a few hours is observed spreading in its track. It has also been found that if seeds are again sown in the following season in a seed-bed which had previously contained many of the above diseased seedlings, the new seedlings will inevitably be killed by the 'damping-off.' As we shall see shortly, this is because the resting spores of the fungus remain dormant in the soil after the death of the seedlings. In other words, the disease is infectious, and spreads centrifugally from one diseased seedling to another, or from one crop to another; if the weather is moist and warm—'muggy,' as it is often termed—such as often occurs in the cloudy days of a wet May or June, the spread of the disease may be so rapid that every plant in the bed is affected in the course of two or three days, and the whole sowing reduced to a putrid mass; in drier seasons and soils the spread of the infection may be slower, and only a patch here and there die off, the diseased shrivelling up rather than rotting."—*Gardeners' Chronicle*.

CINCHONA.—Two excellent papers by Mr. David Hooper were read by Dr. Thresh at the annual meeting of the Pharmaceutical Society which is reprinted further on in our *Tropical Agriculturist*. The subjects are "The Hybridization of Cinchona" and "Carthagena Cinchona." The *Chemist and Druggist* says:—Two authorities discussed the papers and showed how utterly the Indian Government has failed to meet the demands of the markets by cultivating species which do not afford barks that are liked by the quinine manufacturer. This emphasises in a marked manner how wise the Java planters have been in lately devoting themselves exclusively to those barks which are rich in quinine.

COAL IN BORNEO.—Up to the present the borings have only been shallow, not more than 25 feet, when the clay gave place to sand rock but it is hoped that larger beds will be found on Pulo Timbong where the coal yet found appears also to be of somewhat older formation. This latter burns well and clearly, and the Miners, who include some old Labuan hands, say the coal is equal to the best Labuan. It remains to be seen whether it can be found in quantity.—*North Borneo Herald*. [If so, or even if good lignite is plentiful, Borneo may yet be a source of supply for Ceylon.—Ed.]

THE TOBACCO-GROWING EXPERIMENTS IN CEYLON.

Along with almost all the other products of the island the tobacco which had been planted by a German gentleman in the Kurunegala district has suffered greatly from the unusually prolonged drought, many thousands of the young plants having been killed. For some time 200 coolies a day were employed in watering them, but even this expensive expedient could not atone for the absence of rain, and the experiment seems to be a failure for the present, at all events; though we hope the promoters will not lose heart, and trust that better luck will yet attend their experiments in Ceylon.

QUININE FOR THE MILLION.

To Mr. Rivers Hicks of London, a well-known authority on cinchona, belongs the credit of coming forward after a practical manner to popularize quinine and make it available for the million not only in England but in India and we trust by-and-by throughout China. This mail brings us a letter full of interest from Mr. Rivers Hicks which will be published in our next issue, and it also brings us a package of his "four-grain quinine pills" made up in convenient little boxes of "24 doses for 12 pence"; but inside are little pill-boxes each containing two quinine pills of 4 grains each, each such box selling at one penny or one anna. Then this is accompanied by an illustrated pamphlet of 16 pages giving the following information in Marathi, Tamil, Gujarati, Bengali and Hindustani, with pictures of various public buildings in England to catch the native eye. Mr. Hicks has still to serve the Chinese, Burmese, Malays, Siamese and especially the millions of Chinese, who, above all other people, are likely to take to cheap quinine. The letter-press is as follows:—

SULPHATE OF QUININE :

MADE UP INTO THE SAFE DOSE OF FOUR-GRAIN FEVER-PILLS,
MADE BY MACHINERY.

A box containing two pills costs 1s. = 1 anna.

Quinine is well-known throughout India as the only reliable remedy against fever, and is especially so known since the introduction into India of the cinchona tree by the Government of the Empress.

Its value is inestimable to those who, in unhealthy climates, have been in the habit of taking opium medicinally, as quinine produces all the good results to be expected from opium without any of its evil effects.

The beneficial increase in the cultivation of the cinchona has not had a proportionate result in the cheapening of Quinine to the consumer.

The poorer among the inhabitants of India now get some valuable, though inferior, febrifuges at a comparatively low rate, but they do not get the sulphate of quinine which they require. That has hitherto been sold at too high price for them to buy it. It has also hitherto been sold in large quantities than they require, and they do not know the proper dose.

I am, therefore, now offering at the low price of one penny, about equal to one anna each, boxes containing two safe doses of each four-grain sulphate of quinine, made up by machinery into four pills, ready to be taken.

Persons accustomed to taking quinine, or those suffering from, severe attacks of fever, may take much larger doses, even up to as much as twenty grains, but the four-grain is the safe dose, and if taken by any one feeling the first approach of fever may prevent an attack.

These fever pills may therefore be considered as valuable preventives of fever.

Buyers of large quantities, who send £100, will have forwarded to them, carriage paid, to any address in India, 1,000 boxes, each containing two doses of sulphate of quinine, being at the rate of one anna per box.

Buyers of small quantities can have any quantity, however small, sent by post, on forwarding, in addition to 1d for each box the cost of postage.

Minimum parcels postage of 8 annas; so that 8 boxes of pills would cost 8 annas + 8 annas postage, or 16 annas = 1 rupee, whereas 50 boxes would only cost 50 annas + 8 annas postage, or 1 annas = 4 rupees.

THE PETROLEUM VAPOUR ENGINE.

In his address before the British Association, Sir Frederick Bramwell made the following interesting reference:—

"Looking at the wonderful petroleum industry, and at the multifarious products which are obtained from the crude material, is it too much to say that there is a future for motor engines worked by the vapour of some of the more highly volatile of these products—true vapour—not a gas, but a condensable body, capable of being worked over and over again? Numbers of such engines, some of as much as four horse-power, made by Mr. Yarrow, are now running, and are apparently giving good results, certainly excellent results as regards the compactness and lightness of the machinery; for boat purposes they possess the great advantage of being rapidly under way. I have seen one go to work within two minutes of the striking of the match to light the burner. Again, as we know, the vapour of this material has been used as a gas in gas engines, the motive power having been obtained by direct combustion."

The President, having now warmed to his work, waxed bold, and says:—

"Having regard to these considerations, was I wrong in predicting that the heat engine of the future will probably be one independent of the vapour of water? And, further, in these days of electrical advancement is it too much to hope for the direct production of electricity from the combustion of fuel?"

Allusion is next made to various methods of supplying power to householders:—

"Water at 700 lb. pressure per inch is a most convenient mode of lying on a large amount of power through comparatively small pipes."

Again:—

"Power is also transmitted by means of compressed air, an agent which, on the score of its ability to ventilate and of its cleanliness, has much to recommend it. On the other hand, it is an agent which, having regard to the probability of the deposition of moisture in the form of 'snow,' requires to be worked with judgment. Again, there is an alternative mode for the conveyance of power by the exhaustion of air—a mode of which has been in practical use for over sixty years. We have also the curious system pursued at Schaffhausen, where quick-running ropes are driven by turbines, those being worked by the current of the river Rhine; and at New York; and in other cities of the United States, steam is laid on under the streets, so as to enable domestic steam engines to be worked without the necessity of a boiler, a stoker or a chimney, the steam affording also means of heating the house, when needed. Lastly, there is the system of transmitting power by electricity, to which I have already adverted. I was glad to learn, only the other day, that there was every hope to this power being applied to the working of an important subterranean tramway."

Heat-withdrawing or cold-producing engines are next discussed:—"We have in these machines daily instances that, if you wish to make a ship's hold cold, you can do it by burning a certain quantity of coals—a paradox, if ever there was one."

FISH-CULTURE.

(TO THE EDITOR OF THE "AGRICULTURIST.")

Sir,—There is a serious difficulty to be overcome in your suggestion that ornamental waters should be stocked with sporting fish can be accomplished. Trout, which of course, are the species to be first thought of, do not breed unless they have a gravelly stream to spawn in. Now the ornamental waters fed by a subterranean stream of that kind are ex-

ceedingly rare. The others are accumulations of rills, in which trout can find room for themselves only after very heavy rains. If those rills could be gathered into one brook, two or three hundred yards long, most brackish waters would be provided with ample spawning-beds. Now, do you not think that that end could be attained by means of a syphon drawing from the pond water enough to make a goodly sized rivulet into it? If that notion were found practicable, we should have to consider another difficulty. You may put trout into an artificial pond, and even get them to thrive there; but you will not make them rise freely to the angler's fly. They will afford good sport for a few seasons; but after eight or ten years they will not "take" at all, even although they have multiplied enormously. Still, your fascinating proposal is essentially good. The fish would help to keep public waters pure, and as they could be netted, they would add to our supply of food.—I am, Sir, &c.,

ANGLER.

NORTH BORNEO PLANTING NOTES.

(From the *British North Borneo Herald*, Sept. 1st.)

Messrs. V. W. van Gogh and Aug. Koch left for Singapore in the S.S. "Paknam" on the 23rd August. These gentlemen have selected 5,000 acres each on the River Labuk. Mr. van Gogh proposes to be back in North Borneo in about five months time together with Mr. Koch who is a Deli tobacco planter and who will undertake the first planting for the proposed Company. Mr. van Gogh is a Java planter of long experience and it is pleasant to hear him talk with admiration of the soils he has seen on the Kinabatangan and Labuk rivers. He says, "I believe in the future of North Borneo."

Mr. J. Lennards has applied for land on the Benkoka River for Liberian coffee planting. The success attending Mr. P. Christians' clearing at Kudat is sufficient evidence of the suitability of our climate for coffee, and we fully expect to see a large export of coffee from British North Borneo in years to come. The crucial question is, price of labour, and this is a matter that can, we believe, be settled by introducing Tamils, as is now done in the Straits. In this respect we would bear evidence of the good work done by the Muruts lately departed from Padas to Sandakan who are good woodsmen and who have, to our personal knowledge, lately been placed side by side with Sulus when felling jungle with the result that the Sulu Contract was begun before and was not finished while the Muruts faithfully performed their contract. These Muruts are willing to work for, men 25 cents, women 15 cents, a day. On the West Coast these people work for (men) some 15 cents a day and should estates be opened near their villages it seems probable that cheap labour supply could be obtained.

THE CHARACTER OF THE PLANTERS OF BRAZIL

is thus unfavourably depicted by the *Rio News* :—

Some days since a report appeared in the daily papers to the effect that the government had entered into an arrangement with the Banco do Brazil for the advance of pecuniary assistance to planters, the bank undertaking to loan 12,000,000\$ at a maximum of 6 per cent on lands, growing crops, etc., one half of which was to be furnished the bank by the treasury *without interest*. A member of the cabinet has since stated that no agreement has yet been signed, but leaves the conditions of this extraordinary expedient unexplained. It is to be hoped that the government will not make so serious a mistake as that of advancing money to planters to meet the ordinary requirements of their industry. There is no more excuse for making such an advance to this class, than to merchants, manufacturers, rubber-gatherers, or fishermen. The only just and safe policy is to let each industry take care of itself. The planters for whom this assistance is intended are among the largest land

owners of the country, and the producers of an article which enjoys a remarkably secure and profitable market. Almost without exception the prices obtained for this product have left to them a balance of profit, generally a large one. If, then, they have been unable to keep out of debt, then there is absolutely no hope for them. The assistance already given so many times has been of no avail, nor will the assistance proposed today prevent their returning next year for more. The truth is—and it should debar them from all sympathy—they have been so reckless in the use of their money, spending it in the cities in gambling and on wine and women, that they have never been able to improve their estates nor to provide against bad years. To their vices, and not to abolition, is to be charged these troubles of today; and from their creditors, not the needs of labor, come these urgent appeals for money. They are known to be spendthrifts and profligates—those clamoring for assistance—and for this reason, if for no other, they are undeserving of aid. Now, this much ought to be understood, whether in relation to this reported measure, or that of *credit foncier* banks: the enterprising, industrious planter needs no other source of credit than his land and products. If he is a good manager and produces a marketable crop, there will be abundant sources of private credit for all his necessities. This is the experience of other countries, and must be so here. All that is required to secure this is to reform the bankrupt laws and the various provisions of judicial procedure which now prevent a creditor from compelling a debtor to comply with his obligations. The difficulties and expenses of collecting a debt or foreclosing a mortgage, are greater obstructions to credit facilities than any and all causes of which the planters and their sympathisers have thus far complained.

TEENDARREA COMPANY, LIMITED.—During the early part of the season the garden suffered rather from both drought and blight, but latterly rain has been plentiful, and prospects have considerably improved. Work was also seriously impeded by scarcity of labour, the Commissariat Department having offered coolies 8 annas per diem for carrying stores to Sikkim. Labour, however, is coming in more plentifully now, and the Manager anticipates no further trouble this season.—*Indian Planters' Gazette*, Sept. 4th.

MOSQUITOES AND MISCHIEF.—Dr. Finlay, of Havana, is of opinion that mosquitoes are the principal disseminators of the much-dreaded yellow fever. He holds that the sting of this insect, after penetrating the skin of a yellow fever patient, retains on its exterior surface the germs of the disease, with which the mosquito will inoculate the blood of the next person it stings. Hence Dr. Finlay is of strong opinion that yellow fever is spread chiefly by means of insect-inoculation.—*Australasian*.

TRINIDAD.—The last *Bulletin* of the Botanical Department of Trinidad is occupied with a treatise on the cultivation of Coffee, based on a similar work by Mr. Sabonadiere, formerly of Ceylon, but now of Jamaica, and adapted to the requirements of Trinidad, by Mr. Hart. A very important alteration in the procedure has of late taken place, whereby, after the pulp of the berry (cherry of commerce) has been removed, the seeds (beans) may be transmitted to England to have the parchment (endocarp) removed—a process that can be done with much less trouble and expense here than in the colonies, while, provided the "parchment" be kept perfectly dry, the Coffee travels better, and retains the desired colour better, than when the skin is removed on the plantations.—*Gardeners' Chronicle*, Sept. 15th

MOSQUITOES.—Rather late in the day, although the white-banded mosquitoes now devouring us are the most blood-thirsty and venomous of all, the *Scientific American* of 11th July shows how the tormenting insects can be banished from our rooms. The paper says:—*To expel mosquitoes* take of gum camphor a piece about one-third the size of a hen's egg, and evaporate it by placing it in a tin vessel, and, holding it over a lamp, taking care it does not ignite. The smoke will soon fill the room and expel the mosquitoes, and even though the windows should be left open all night, they will not enter the room as long as the odour remains.

TEA: NEW CONSTITUENT.—At a recent meeting of the Berlin Physiological Society, Professor Kossel announced the discovery of a new constituent in tea, to which he has given the name of *theophyllin*. The physiological action of this is still under investigation, and if it proves to be a stimulant, as supposed, and does not exist in coffee, the cases of people who can drink strong coffee with little nervous disturbance, but are excited by tea, are explained. They have become tolerant of the theine which exists in both tea and coffee (as opium-eaters become tolerant of morphia in moderate quantities, arsenic-eaters of arsenic, smokers of nicotine, etc.), but not of the theophyllin, which operates upon them with a fresh energy comparable to the nicotine of the schoolboy's first cigar.—*Times of India*.

TEA IN 1784.—The following is an old grocer's bill of 1784 (the year of Dr. Johnson's death), which shows the price of tea at that period:—

Mr. Pritt.	London, 1784.			
	Bot. of Geo. Roberts.			
Fine Congou tea ...	1 lb. ...	@ 6/8 ...	£,	6 8
Fine Spk. Lf. Singlo ...	1 ...	@ 8/ ...	"	8 0
Loaf Sugar ...	14 ...	@ 84 ...	"	9 4
Supr Fine Hyson ...	1 ...	@ 16/ ...	"	4 0
Fine Souchong ...	1 ...	@ 10/ ...	"	2 6
Mt. Sugar ...	4 ...	@ 5d ...	"	1 8
				51 12 2

Rec'd the same time, G. Roberts.
 Dr. Johnson, as Macaulay says, was in the habit of seating to his "thirty-seventh cup of tea" when he was asked out, he must have been rather an expensive acquaintance.—*Oriental Mail*.

LIGHT OR ROAD RAILWAY. The *St. James's* has the following note, and the subject deserves further inquiry, in the interests of Ceylon:—"Mr. Sellon has been reading down at Bath a paper in favour of 'Light or Road Railways,' and fortifying his arguments with facts drawn from the experience of the Wolsingham and Stony Stratford Company. This line has only been working, it appears, some eighteen months; but it already carries the entire population of the district once a week besides dealing with the whole of the goods, parcel, and mail traffic to and from the main London and North-Western line. Though this is not the only line of the kind in the country—as there is Lord Wantage's line at the station of the same name, and another, we believe, in the neighbourhood of Wisbech—there can be no doubt that the system is capable of very extensive use. On the Continent they are well aware that many districts can support a light railway, whose traffic would not justify the construction of heavy engineering works. In the country parts of Holland it is especially there is hardly a market town which has not its line of narrow tramway running up into the station-yard. Mr. Sellon does well to insist on one point, that the line shall be of standard gauge, so that trucks may pass from railway to tramway and vice versa without the delay and injury which must always be caused by the process known as 'breaking bulk.'"

THE BOTANIC GARDENS, TRINIDAD.—When Mr. Hart scarcely more than a year ago, assumed the superintendence of the gardens, he found them in rather a backward and dilapidated condition. An interregnum of twelve months had intervened between his appointment and the retirement of his predecessor, and during that time the gardens had been under the superintendence of a clerk from the island Audit Office. The work was done as well as could have been expected; still many things were out of order, and many improvements had instantly to be made. Mr. Hart set vigorously to work, and with the efficient co-operation of his Excellency Sir William Robison, K. C. M. G., he has been able to do wonders. We admire his courage and his ability, and we sincerely wish him all success in his important labours.—*Gardeners' Chronicle*.

THE RECENT "RIG" IN COFFEE has caused large fortunes to change hands in Hamburg, and it is believed that "bear" operators in London, who have been speculating through the Hamburg and Havre Clearing Houses, have incurred loss. The estimated liabilities to deliver Santos coffee in Hamburg at the end of September are about 100,000 bags. Of this amount about 30,000 bags are on passage, so that a residue of 70,000 bags must be delivered either from existing stocks, or carried over until the next month. The moving spirit of the rise is stated to be a Hamburg firm, which has dealt hitherto very fairly with the bear operators, but the matter has now entered on a new stage, the Hamburg Liquidation-Kasse having given out that it will book no further engagements for September, unless the sellers bring a guarantee of their ability to deliver. The unprecedented advance has been from 86 pfennig per lb. on the 4th inst. to 250 pfennig on the 7th. At the last figures the "bulls" nett according to report some £2,000,000 sterling. At Antwerp the same wild gambling is going on. Measures are demanded to put a stop to this abuse.—*L. & C. Express*, Sept. 14th.

"THE TEA WE DRINK" is the subject of a long discussion in the London *Standard* files, chiefly through correspondence, but also editorially, and good cannot fail to result to the producers of the pure article. Several old colonists at home send us copies of the issues, and Mr. John Hughes writes a letter on the subject which will be dealt with later on. The ball was opened by a tea-planter signing "B. M.," who wrote "to protest against the vile rubbish now being sold in London and all over the country as tea." A shoal of replies followed from "Mincing Lane," "A Merchant," "Export," "Manager of a Tea Company," "Indian Tea," "C. S.," "Mercury," "W. E. W.," and so on. Some of the letters are amusing reading. We make one extract now concerning ourselves more particularly:—

"With reference to the remarks of 'Mincing Lane' about Ceylon C. S. writes:—Let me assure you that the soil of Ceylon is not at all likely to 'give out.' The tea plant is a deep feeder, with a long tap root, which touches a soil which may be called virgin, and of which there is a great depth all through the tea districts of the island; and as to quality, that will improve as the bushes mature. The finest tea comes from the oldest gardens. There is, I believe, a marked similarity between Ceylon Tea and the fine qualities of China which used to reach this country; and it is owing to this that Ceylon is in such demand. But 'Mincing Lane' is wrong in stating that there has been a decided reaction lately in favour of the two teas—it may be so in the case of China—but Ceylon has been in favour all along. Another correspondent says:—The writer who signs himself 'Mincing Lane,' today must have a peculiarly constructed palate when he can drink and enjoy old Congou. Such a palate would hardly discriminate between carbolic acid and Irish whisky."

THE HYBRIDISATION OF CINCHONAS.*

By DAVID HOOPER, F.C.S., F.I.C., GOVERNMENT
QUINOLOGIST.

Cinchona hybrids have received a great deal of attention from a number of botanists, and in the present paper the author treats the subject, so far as cinchona is concerned, in the light of the chemical analysis of the barks.

Between *C. succirubra* and *C. officinalis* many hybrid barks are recognised, and have been cultivated and exported to a very large extent. The facility with which these plants made their appearance on the estates seems to imply that forms of cinchona were produced that were more adapted to the climate and situation of their adopted country than the parent forms brought originally from South America. Those having a greater vigour of growth should be propagated, as the robust habit is usually indicative of a richer bark. Hybrids assume the quick growing character of the *succirubra*, yet they contain a greater proportion of quinine than that species. They do not, as a rule, contain the percentage of quinine usual to *officinalis*, but the large quantity of bark yielded by the trees and the high total alkaloids make them equal in value to the best crown barks.

The author proceeded to give the alkaloidal composition of two species between which hybridisation on the plantations has taken place, the natural stem bark being selected. The results were given in a table representing fifty selected red barks, the quinine ranging from 17 to 27 per cent., cinchonidine from 26 to 51 per cent., cinchonine from 17 to 47 per cent., and amorphous alkaloids from 4 to 23 per cent.; besides these the alkaloid quinidine occurred in traces in red barks, and occasionally reached 0.5 per cent.

The average of the fifty total alkaloids was 6.25 per cent. The table further showed that, with the exception of five samples, all were official barks. During the discussion on the present Pharmacopœia, a critic remarked that the test admitted barks containing $2\frac{1}{2}$ per cent. of quinine and $\frac{1}{2}$ per cent. of cinchonidine or those containing $\frac{1}{2}$ per cent. of quinine and $2\frac{1}{2}$ per cent. of cinchonidine with 3 per cent. of other alkaloids, but it was the opinion of the author that it would be very surprising to find such an erratic composition in any one kind of cinchona.

The average composition of the alkaloids, derived from the foregoing analyses, shows the following percentage composition:—

Quinine	1.40
Cinchonidine	2.25
Cinchonine	1.92
Amorphous alkaloids68
					6.25

In *cinchona officinalis* there is a different arrangement of alkaloids, fifty specimens showing that the quinine ranged from 48 to 62 per cent., the cinchonidine from 18 to 33 per cent., the quinidine from 0 to 6 per cent., the cinchonine from 2 to 16 per cent., and amorphous alkaloids from 4 to 13 per cent.

The crown barks in this table give an average of 5.25 per cent. of total alkaloids, viz.:—

Quinine	2.93
Cinchonidine	1.40
Quinidine08
Cinchonine42
Amorphous alkaloids42
					5.25

Calculating from these figures, a hybrid of the two species ought to yield:—

Quinine	2.16
Cinchonidine	1.82
Quinidine04
Cinchonine	1.17
Amorphous alkaloids56
					5.75

* Papers by Mr. David Hooper read at the annual meeting of the Pharmaceutical Society by Dr. Thresh

Analyses of twenty-five specimens of hybrid bark (*magnifolia* and *pubescens*) showed that the centesimal composition of the total alkaloids gave on an average:—

Quinine	41.2
Cinchonidine	40.9
Quinidine	0.5
Cinchonine	9.7
Amorphous alkaloids	7.7

The following analyses show the distribution of the alkaloids in individual barks:—

	Quinine	Cinchonidine	Quinidine	Cinchonine	Amorphous Alkaloids	Total
1 Hybrid	3.32	2.99	—	.41	.49	7.21
1a "	2.58	2.91	—	.43	.63	6.55
2 "	.87	.98	.13	2.96	.70	5.64
2a "	.90	2.75	—	1.05	.40	5.10

The two barks marked "1" and "1a" are in appearance like the pubescent hybrid, and their analysis confirms to some extent the resemblance, in that they contain a large proportion of quinine and cinchonidine in their alkaloids. Nos. 2 and 2a have the habit of the *magnifolia* hybrid, but the presence of quinidine and the large amount of cinchonidine and cinchonine respectively indicate new features in the alkaloidal composition that might be referred to new forms produced by hybridisation.

Some analyses of hybrids grown in the Bengal Government cinchona plantations, at Mongpoo, near Darjeeling, at 3,500 feet elevation, showed the difference between hybrids from foreign localities grown in the same situation. The three kinds were from trees raised from seed from Jamaica, the Nilgiris and Monpoo, and each sample was taken in strips from about forty trees of varying types.

	Jamaica.	Nilgiris.	Mongpoo.
Quinine	2.22	2.47	2.02
Cinchonidine	1.93	1.98	2.50
Quinidine	—	—	.17
Cinchonine	.75	.58	.66
Amorphous alkaloids	.64	.59	.31
			5.66

In concluding, the author expressed the hope that he might in a future communication give the results of a large number of analyses of the ledger-hybrid, a cross between *C. ledgeriana* and *C. succirubra*.—*Chemist and Druggist*,

CARTHAGENA BARK.

By DAVID HOOPER.

In the initiatory part of this paper the author gave some historical data regarding the barks bearing the name of Carthagenia in the United States of Colombia.

José Celestino Mutis explored the bark region of New Granada in 1772, but it would seem that he was not acquainted with the more valuable species of cinchona.

Alexander von Humboldt, who visited the ports of the Caribbean Sea in 1801, stated then that "the proximity of the port of Carthagenia would render the neglected cultivation of cinchona an object of great importance to European trade; while Dr. Karsten, a German botanist, stated in 1844, as the result of a long residence in South America, that he found *Cinchona lancifolia* of Mutis to be a very variable plant, and to furnish barks of very different appearance. This species, he says affords principally two kinds of barks: the valuable variety called soft Colombian, or Calisaya, or Santa Fé, and the less valuable variety, called Carthagenia, or Cogneta bark, or Carthagène ligneux of the French. About the year 1872 Colombian barks were again in the market, and 12 cwt. was shipped to Europe from Carthagenia and neighbouring ports. After referring to the production of bark in the United States of Colombia at the present time, Mr. Hooper proceeded to state that Mr. Robert Cross was employed in 1877-1878 to collect plants of the Calisaya Santa Fé on the eastern Andes, and of the

Carthagena bark on the Central Cordillera. He brought home five specimens of the latter from Cauca Valley, and one from Coralis Luza, in the district of Magdalena, and the latter was the only one that was found to contain quinine by Mr. J. E. Howard, who analysed them, the amounts of total alkaloids being found to be 2.91, 3.68, 0.44, 3.76, 4.75, and 2.72 per cent., the fifth of these only containing quinine (1.88 per cent.).

The plants were reared in Kew before they were sent out to India, and this year some bark was taken from an original tree six years old, on the Government plantation, and examined, with the other specimens, with the following results:—

	Government Stem-bark.	Ossington Stem-bark.	Ossington Root-bark.
Quinine ...	—	—	1.10
Cinchonidine	.40	.22	.55
Quinidine ...	—	—	.36
Cinchonine ...	1.64	1.60	1.77
Amorphous alkaloid	1.51	1.33	.62
	3.55	3.15	4.40

The appearance of the bark was not very different to that of other species; the outer surface was marked by transverse rings at rather regular intervals and warty exuberances. The powder of the stem, and especially of the root-bark, was decidedly more yellow than other kinds of cinchona. Although this bark is known in some quarters as "hard Carthagena," no particular hardness was noticed in the small sample from the locally-cultivated trees; if the hardness depends upon the heaviness the name would not apply to this bark, as the specific gravity of some of the powder showed it to be like the Cuprea, lighter than the red and crown barks. The analyses, however, are of the most importance, and these show the bark to have the same composition as those brought by Mr. Cross from Usenda and Sylvia, in the district of the Cauca, and analysed by Mr. J. E. Howard in 1878.

It is very evident that this variety of Carthagena bark, now being cultivated on the Nilgiris, is a very useless one commercially, and that the better kind, brought from the Magdalena Valley, never reached India at all, or was one of the plants that was unsuited to the climate and died. It is not likely that the propagation of this species will be continued now that its exact value is known.

In concluding the paper the author acknowledged the assistance he had received from the works of various authors, and the statistical notice of the cinchona trade in the *Pharmaceutical Journal* and the *Chemist and Druggist*.

The PRESIDENT, in moving a vote of thanks, expressed his pleasure that the Conference was selected as the medium for the publication of such important papers as these.

Mr. GROVES said he felt interested in this question of hybridisation, and would like to know if there was any one who could tell him what was the influence of the parent on the nature of the bark. For instance, if a tree was rich in alkaloid, should that not be taken as the parent rather than the other, which might not be so rich?

Dr. B. H. PAUL, rising in response to the President's request, said that he would like to point out that the manner in which the analytical results had been placed before them illustrated in a very graphic style the disastrous results which had followed the introduction of cinchona into India. (Laughter.) No one could judge from the figures given what was their real significance. It so happened that the selection of red cinchona for cultivation by the Indian Government was made during the absence of a large lot of bark, and that selection had to be followed by great disaster. The reason of that was that the bark contained so much as worthless a kaloid, of cinchonidine, and cinchonine that no manufacturer would have anything to do with it. As long he could get more workable barks. Crown bark

was better in this respect, and the effect of cultivation upon the bark had been rather to improve it, but what he wished to emphasise particularly was that the red bark contained so little quinine in comparison to the other alkaloids, that its cultivation had succeeded in well-nigh ruining the planter, the quinine maker, and everyone who had anything to do with it. There was the proof of it: cinchonidine and cinchonine were running all over the table, and they were no use to anybody. As to crown bark, while he said that it was better than the red, he should like to add that it also was of little use unless it gave from 3 to 5 per cent. of quinine. He then proceeded to criticise the figures on the table, pointing out that the quinine was quite swamped by the less valued alkaloids, and his comments thereon created much hilarity, as also did the remark that the attempt to cultivate the comparatively worthless Carthagena bark was another example of the superlative wisdom of the Indian Government. He objected to the propagation of the existence of these South American barks which experience in cinchona culture elsewhere has shown to be of no account, and in concluding again referred to the red bark and its introduction into the B.P., the result of which was that every article containing cinchona was "an officially adulterated article," each 1 per cent. of quinine having from 2 to 3 per cent. of valueless products to keep it company.

Mr. HONGKIN followed in a very similar strain, pointing out to begin with that confesional figures were exceedingly misleading, and this fact, he regretted to say, he had learnt as a manufacturer of quinine. He was doubtful, too, as to the correctness of Mr. Hooper's figures, and was of the opinion that those referring to the crown bark, for example, had really been got from the examination of Hybrid barks. Otherwise he could not account for the ratio of the percentages. Cinchona culture on the Indian Government plantations had not been very successful, and it would not be until the authorities took some hints from the Java planters, who had confined themselves latterly to the cultivation of calisaya hybrids, which gave bark containing as much as 6 and 8 per cent. of quinine. He regretted that nothing was said in the paper about the cultivation of cinchona robusta, a hybrid which had sometimes yielded as much as 4½ per cent. of quinine; but what he particularly urged was that the Indian Government should go in for the cultivation of those valuable barks which had proved so successful in Ceylon and Java. In reply to Mr. Groves, he stated that the selection of the parent in hybridisation made a distinct difference—for example, if a calisaya was the parent, it gave a better bark than if a succirubra was the parent.

Dr. THRESH having explained that Mr. Hooper's paper gave figures which answered much of the criticism of the speakers, this concluded the solid business of the meeting.—*Chemist and Druggist*.

PERADENIYA GARDENS.—Mr. W. T. Thiselton Dyer, C.M.O., in his presidential speech before the Biological Section of the British Association at Bath, said:—"This Association has made a small grant in aid of the establishment of a laboratory in the Royal Botanic Gardens at Peradeniya, in Ceylon. It may be hoped that this will afford facilities for work of the same kind as has yielded Dr. Treub such a rich harvest of results in the Buitenzorg Botanic Gardens in Java."

FISH-CURING YARDS seems to be prospering in Madras. We have an order of Government before us directing the transfer of eleven temporary fish-curing yards to the permanent list, thus raising the cost of the permanent establishments from Rs. 5,500 to Rs. 20,000 a year, and the cost of the temporary yard imposed in the permanent yards from Rs. 100 to Rs. 1,000 a year (the period of employment of these temporary establishments is now limited to six months in the year); a revision of the temporary establishments at temporary yards resulting in a reduction from Rs. 1,175 to Rs. 600 a year. The sanction to these establishments will remain in force during 1888-89 only.

CUTCH: ITS MANUFACTURE AND TRADE.

One of the most important articles of produce after rice, exported from Burmah to Europe, is cutch. The trade in this commodity has been steadily increasing during the last twenty years; and though in 1885-86, there was a sudden decrease in the exportation owing to the troubles arising from the annexation of Upper Burma, nevertheless the trade has to-day regained its former activity, and last season's supply was equal to, if not greater than, that of late years. As soon as affairs settle down more peaceably throughout the country, road communications have been opened out, and proper facilities given to the Burmese to work the cutch trees, which abound in the forest tracts of Burmah, there is not the least doubt but that this industry will assume greater dimensions. The cutch sent to the markets will also be of a better quality and far superior to the lot of adulterated and inferior stuff which now finds buyers amongst our merchants and gives rise to the very serious complaints made by brokers in Europe and America. The cutch tree (*Acacia Catechu*) is found in large forests throughout the whole of Burma. The core or heart of the tree is a dark-red wood, like in appearance to mahogany; this wood is chipped, boiled and the extract is what we term cutch—Burmese *Tha*; in other words, according to Dr Mason, it is the inspissated extract obtained by boiling chips of the wood. This industry is generally carried on by inhabitants of villages situated on the skirts of forests, as also by those able-bodied Burmese not given to Agricultural pursuits, or who, not being rich enough to possess a couple of bullocks or buffaloes are unable to till their lands. The only requisites needed are a pair of strong and willing arms, a dah and a cooking or boiling pan. In the month of October, when the rains have ceased the cutch-boilers make their arrangements. Those who do not live in the vicinity of the trees, and who comes from a distance for this special work, form into companies of threes and sixes and so on; whilst whole families living in the neighborhood, devote themselves to the manufacture of this article. Certain spots are selected, where a choice of good robust trees may be had. Small pits are made and so formed that the pans can remain in a fixed position, so as to avoid any tilting when charged with the manufactured material. The labor of felling the trees now begins; of lopping the branches, of stripping the bark and cutting the outer wood, until the core is reached. The younger members of the family have now their task, *viz.*, of chipping the dark-red pieces of wood remaining. When a large quantity of these chips have been collected, the boiling process is taken in hand. One Burman superintends three pans into which, partly filled with water, the chips are put. The fires are now lighted and cooking proceeds. The Burman, who has this part of the work in hand, is generally well up to the business and is careful that the boiling mass does not get overheated or burnt. When of the desired consistency or thickness, the sap or cutch being drawn by the heat from the chips, the contents of the pans are spread out on mats for evaporation; care being taken that the dregs or woody refuse be discarded. These mats are laid out in a cool shady and dry place, where the cool breeze can play upon the liquid mass. The evaporation goes on gradually, and in a short time the workmen are enabled to manipulate the cutch and fashion it into blocks, which measure about 12" x 7" x 5". This is the size of good pure cutch offered in the market; but there is no hard and fast rule in this respect. The block generally weighs from 4 to 6 viss; the color red, dark-red and black; these shades depend principally on the quality of the chips used, whether of a young and robust or one of many years growth; or to the duration of the time taken in boiling. The light red and red cutch is considered of the best quality and is made into small tablets; more care and attention is paid to this quality and is taken up principally for local consumption, as it, with betel-nut, chunam and the pan leaf, constitutes the Burmese *chewing quid*. It is exported also in small quantities for the same eating purposes to India. The dark-red and black are the varieties prepared largely for the markets of Europe

and America, and it is with these qualities our merchants of Rangoon have principally to do. A block of pure, unadulterated cutch presents as a rule, the following characteristics. It the block has been allowed sufficient time for evaporation and to harden it will have a uniform appearance, probably cracked on the sides; dimensions the same as already given; weight from four to six viss; taste bitter, acrid or pungent; smell something like that of opium, and, if it is thoroughly dry, the block can be easily broken, with a tendency to *crumble*, and, on the other hand, if there is still moisture in the centre, there will be a *glaky* appearance. The more it approaches the light-red color, the better quality it is. If therefore the cutch to be sold should show to any perceptible extent a falling off in any of the particulars enumerated above, it may be safely put down as of an inferior kind and adulterated. Of course large quantities are brought to the market in a soft condition owing to the eagerness and hurry the cutch-boilers have in their desire to be early in the market when prices are rising high. When the commodity arrives in this condition, the test consists in the smell and bitter taste. It will be understood, the more liquified it is the greater will be the loss in weight when it dries up or by the time it reaches the home markets. In former years merchants were pretty safe in the purchase of the genuine articles as the quality known as *Mindoon pure Cutch* was invariably manufactured; but of late years, owing to the steady demand, keen competition and enhanced prices, a greater stimulus has been given to the trade and unfortunately greater liberties taken by cutch-boilers in mixing and adulterating. *Than Sha*, a spurious kind of cutch is used for this purpose. Some eight years ago, it first became known to the trade; its value at that time, was about R8 to R10 per 100 viss, but the sale was slow; now a greater demand has sprung up, and the quotation last season for this spurious article was R25 per 100 viss.

There are also several other varieties of inferior stuff manufactured; some designedly, as by the mixture of fibrous matter, sand or earth; some, through overheating, the quality of the wood, or carelessness on the part of the cutch-boilers. These are called, *Sat-sha*, *Nay-lan sha*, *Teven-loun sha*, *Pet-tok sha*, etc.

A little experience will soon familiarize the European buyer with these deceptive sorts, if he keeps in mind the general particulars given for pure unadulterated cutch. Those that are mixed with sand or earth for the purpose of increasing the weight, may be detected by the heaviness of the pieces or by the grittiness of the stuff when placed between the teeth. We would recommend merchants who do largely in this business, to insist on their European assistants, acquiring a good practical knowledge of the article. A careful examination of the different lots which in season are daily offered for sale, will afford many opportunities to these assistants of spotting, so to speak, the good from the bad. If assisted at the onset by some experienced Burman and by the aid of the ordinary testing rod, there is no reason why in a few weeks' time they should not become fair judges of the quality they are buying. Again, if feasible, purchases should be made by sample. It happens too frequently that, owing to keen competition, Chinamen will insist on your taking the whole parcel as it is brought in the wagons, or as it lies in the godowns, without choice or selection, and that at prices which should be for the best quality only.

The Chinamen take good care when buying for themselves direct from the Burmese traders to classify the cutch as it arrives in carts or boats from the interior, and to pay according to their classification. For example, if the rate for good hard cutch is R37 per 100 viss, they will give for good soft R25 to 30, for *Sat-Sha*, or mixed kinds 18 to 25; for inferior stuff, *viz.* that mixed with earth or sand 8 to 12 per 100 viss. In almost every cart or boat some pieces answering to the interior description will be found, and when a parcel is made up and sent down to Rangoon, the good, bad and indifferent are sold in one lot and at one uniform price. If

then, the merchants should agree amongst themselves to buy only according to quality and care be taken to separate the good from the inferior, we feel convinced that a healthy reaction would soon take place and that Burmese and Chinese would be forced to offer a good pure and unadulterated article in the market. We may again have occasion to refer to this subject and will probably write a few words on the manufacture of Siam Cutch.—*Rangoon Chronicle.*

THE MATALE AGRI-HORTICULTURAL EXHIBITION.
(Communicated.)

The Agricultural Society of Matale is to be congratulated on the financial success of its second Exhibition. The subscriptions exceed Rs600 and over Rs50 was collected at the gate during the three days of the Show. However, the unimproved agricultural and industrial advancement of the district cannot be traced from the poor display of exhibits that were placed on the tables. The quantity and quality were much inferior to last year. It can only be called a pleasant social gathering, where old friends met to renew the happy scenes in the days of old King Coffee. I would advise this Society to rest for the next three years and give other places a chance of coming forward. The refreshment arrangements were nil and severely commented upon by all the visitors. Few could procure a cup of tea. Mr. D. Joseph's catering was of the poorest description. As I turn over the pages of the catalogue a few notes on the different classes may interest those that were not present.

CLASS I.—GARDEN PERENNIALS IN POTS.

Poorly represented. Only 2 exhibits that received awards, shown by Mr. Greve stationmaster, who is a worthy example to all—a true florist and keen cultivator. I have not seen a more tastefully arranged garden in Ceylon, and at present the display of bloom is magnificent and well worth a journey to Matale. Two exhibits of roses in pots were brought inside the buildings, and how the owners ever imagined the Judges were to award honours to such rubbish remains a puzzle.

CLASS II.—GARDEN ANNUALS IN POTS.

One exhibit from Mr. Greve.

CLASS III.—FERNS AND ORCHIDS.

One poor collection from Mr. Greve. 8 orchids from Nuwara Eliya district were very creditable. 3 good specimens of golden fern and 1 adiantum fern were sent from Colombo, the only good plants in the show.

CLASS IV.—FOLIAGE PLANTS.

3 exhibits of miserably good stuff.

CLASS V.—TREE FLOWERS.

Blossoms. One good exhibit from Mr. Reeves, large blossoms, but badly shaped. Stands of phlox, hibiscus with some new forms, Zinnia, chrysanthemums, and Indian pinks from Mr. Huxley, arranged with great taste in proper flower boxes. Mr. Grove's exhibits were also well-shown. Mr. Barber exhibited several nice boxes of flowers grown at Ukkwala. Bougainvillea, Hibiscus, and others were the most interesting, and some of the flowers I have ever seen on a table. After all the advice given by Mr. Nock in your columns, one would expect to see improvement in taste of colour and arrangement. The most of the bougainvillea resembled a college yard. Some neat but whole bougainvillea were sent by Miss Gray, much improved with the addition of flowers.

CLASS VI.—VEGETABLES.

Miscellaneous. Only 2 collections, one grown in Matale district by Mrs. Booth, "who does everything well." The other from Nuwara Eliya by Mr. Whyte. Tomatoes three entries.

CLASS VII.—FRUIT.

Very poor, everything green and unfit to place on a table.

CLASS VIII.—NATIVE PRODUCTS.

One would expect to see the Matale population in such a production. Several from Matale, but "the Matale" address read to me by Arthur Gordon by the worthy hand of Bandarapola must have been prepared before the composer visited the Show, other wise

the superlative language used in expressing the resources of the district might have been considerably modified. The request for an additional train drew forth a real "sardonicus risus" from the viceregal party. Only 3 collections of paddy and rice were staged for the gold medal. Nuts and other small grain, very indifferent.

CLASS IX.—ESTATE PRODUCTS.

2 entries for the collection, and the prize lot contained nothing worthy of special notice.

The samples of tea were very good, both fancy and commercial; but a poor representation under a dozen exhibitors.

Coffee Arabica 3 samples, small-sized bean.

Liberian 4 samples. The prize lot from Matale North estates very fair.

Cocoa 4 entries. The finest sample being disqualified, as the judges declared it was picked. The exhibitor denied the charge.

Cardamoms a few good samples, but the best lots were over steamed and boiled. Strange that grower will not produce the fruit in its natural state. Any artificial preparation destroys the flavour of this valuable spice.

Cinchona 3 exhibits. The succirubra from Mr. MacFarlane, Maskeliya, was very fine.

The annatto exhibit from Crystal Hill was very interesting.

Vanilla, indiarubber and pepper comprised a few samples.

Tobacco leaf from Mr. Vollar was fine and well cured.

Cigars.—Bandarapola sent an exhibit of green and uncured leaf, a very spotted looking article. I consider this class the worst represented in the Exhibition.

CLASS X.—LIVE STOCK.

Few entries, and those shown wretched specimens, except two cows which were in good condition.

Poultry and Ducks.—A few good pens.

Fresh Butter, judged by Mrs. Watt, Mrs. Williams, and Mrs. Alexander. 6 entries, all excellent quality and keenly contested by ladies from the granite county, and well they upheld the renowned fame of that agricultural county, Aberdeen. The egg award went to another Aberdeenian. Beagles were represented by 2 mangy couples.

CLASS XI.—ARTS AND MANUFACTURES.

Gold, silver and brass work comprised some lots of beautiful workmanship and artistic designs.

Jewellery, in the usual Ceylon style, were displayed.

Ivory carving, included a beautiful exhibit from a wihara in N.-W. Province.

Pottery and Mats.—Chiefly the ugly red and yellow pots made about Kandy.

Woodwork.—An exceedingly neat collection of fretwork was shown by Col. Ser. Doran, Kandy, and some small tables inlaid with Ceylon woods were exhibited by the Industrial School, Kandy, but defective in arranging the colours. The fancy work from R. O. Convent, Matale, was very pretty, and I observed several nice samples of woolen articles. Planters, "bachelors in particular," can be well suited there with a useful pair of hose, at a moderate cost. Mending is also undertaken.

The lace and embroidery work was beautiful.

CLASS XII.—BEEF AND MUTTON.

Beef and mutton &c, two entries.

CLASS XIII.—PRESERVES.

4 exhibits for this class and one good set of preserves received an award from the fair judges.

CLASS XIV.—MISCELLANEOUS.

Tea Brand.—Three competitors entered for this prize, but the judges considered the suggestions too poor to award any prize.

Messrs. SREEN & Co. exhibited a collection of photographs in neat frames, mostly native women in a state of nudity.

A considerable amount of discussion arose over the tea brand, as the Committee intended to change of Class IX disqualified entries from the gold prize, as they were not manufactured in the island.

Captain W. H. Lewis and Mr. Barber of the bank was the only machinery in the Exhibition. A propeller and other machinery was manufactured in the island, but the machinery.

The adjoining shed contained workers in silver and brass, also lacquer workers, ornamenting walking-sticks, their chief substance being Waterlow & Sons' wax. The weaving of cloth was done in a very primitive fashion by villagers from Laggala side.

On Saturday I observed the Hon. W. W. Mitchell and Mr. Holmes going carefully through the Show, and found quite a point of much interest in a beautiful sample of Fiji cotton, grown by Mr. Wejekoon, Matale.

One of the chief exhibits of interest came from Mr. P. C. Braine, Woodslee, illustrating sericulture.

Your correspondent who reported the proceedings on the opening day must have been a stranger in Matale.

BY A COLOMBO VISITOR.

It is in accordance with the views of intelligent gentlemen expressed through the public press that Agricultural Shows are becoming fashionable. Kandy, Kurunegala and Kegalla have been to the front, and success has invariably been the result. Matale followed suit, and from all that appeared in the papers about last year's Show, Matale does not appear to have been behind-hand in any respect. When the present Show, just over, was announced, great was the attraction which drew not merely sight-seers and holiday-makers but even practical men. It must be admitted, however, that the attraction was far in excess of the actual interest attaching to the Exhibition and the summary of its results. This remark applies chiefly to the exhibits of "native products," which were of the poorest. It does not in the least affect the credit due to the indefatigable exertions of the Assistant Government Agent, Mr. Burrows; but if it does prove anything, it proves how feebly his efforts are seconded by his native lieutenants and the leading agriculturists of the district—always excepting Mr. Charles De Soysa. To the credit of that gentleman and his superintendents, it must be said that he scarcely misses a single Show, but is always to the front with the products of his estates; and he cares more for the influence of his example than for gold or silver medals. If others of the landed gentry of Matale, who pride themselves over the many broad acres they own, were to imitate his example, there would be no occasion for Sir Arthur Gordon to express, as he did, his regret at the poor show of native products. But that the natives do not either enter into the spirit which promotes these Shows, or do not quite understand their object, would appear from the greater eagerness and interest with which they press forward and crowd themselves to suffocation in order to witness the wild, grotesque and ugly performances of some Kandyan dancers than to examine the exhibits of the products of their own cultivation. The result is just what might have been expected. Of six gold medals only two were won by natives, viz.—For paddy by Mr. T. B. Aluwihara and another for tea by Mr. Soysa. Of silver medals only one was won by Mr. H. Alwis for a table bouquet, whilst not a single native would appear to have won any medal at all for what may be regarded as strictly "native products," viz.—tobacco, cardamoms, pepper, tomatoes, annatto, poultry, butter, &c. In strong contrast to the apathy or something worse of the natives, the Europeans of the district and conspicuously so the planters have mustered in full force, and to their zeal and energy is due the success of the Exhibition such as it was. Prominent amongst these was the laird of Bandarapolla, Mr. H. Fraser, who seems to have worked with a will and energy not inferior to the Assistant Government Agent, whilst contributing no mean share in the products exhibited. Mr. Gordon Reeves comes next, and the well-known Mr. A. G. K. Borron would yield the palm to none in exhibits of general estates products perhaps beginning with arecanut and ending with vanilla.

The Liberian coffee exhibited was the best I have ever seen, and the cardamoms were of the purest white and full flavored.

I visited the Exhibition a day if not two days after the fair; and yet it was the flower and fern department which lent a charm to the Exhibition and

made it almost a fairy scene. On returning to take the train late in the evening, I found to my surprise that so far as flowers were concerned the station grounds might as well have been referred to as the best exhibition of them, and if names do not mislead me, I believe the stationmaster himself was the largest exhibitor of flowers, and it would be well if other stationmasters followed his example. But tastes differ. On my return journey I observed that one stationmaster has a partiality for the *lantana* weed; another prefers *cholan* or maize; a third, more frugal, grows peas, beans, and other vegetables to meet the daily demands of the housewife, whilst the last I observed was apparently one who cannot bother himself with these trifles. He goes in for stately trees—a *jak* here, a *jak* there, with *plantain* interspersed.

A hideous picture—the production of a native artist—was pointed out as a likeness of the last King of Matale—a picture by no means complimentary to his late Majesty. My friend naively remarked that the subjects of so ugly-looking a specimen of royalty cannot be very good specimens of physical formation. But the appearance of some Kandyan ladies in their graceful native costume made us considerably modify our opinion. Perhaps the race has improved since his Majesty ceased to reign. But whatever the physical features of some few females, the general appearance of the majority of the population, male and female, reminds one that Matale borders on the Vanni, and that the people have to sustain existence on very scanty fare. Unfortunately "there are not the vital statistics to refer to, but it would be interesting to note if the rate of mortality bears out this view of the population.

The Volunteer Band from Kandy went in the same train in which I travelled, and when they were seen in the Exhibition grounds, there was quite a rush to see them, many in the crowd exclaiming "Oh! that will be better than anything we have yet seen." The entrance fee to the Exhibition on the 3rd day was 12½ cents; but the young chap who presided over the ticket department said, that if we left the grounds the same fee would be paid over again; rather an inconvenience this, as the refreshment room had become a snare if not a delusion on the 3rd day; the constable who mounted guard over it assuring us that if we once got in, he would on no account allow us to go out without a ticket from the Secretary, and, as we prized personal liberty more than creature comforts, we did not care to make this bargain. Unfortunately neither Mr. Daniel Joseph nor his exhibits of capsicum were to be seen anywhere within the grounds.

A NOTEWORTHY feature of the year, as regards the effect on the British carrying trade in tea, was the falling-off in shipments by the Suez route, the greater portion of this decrease amounting to about 4,000,000 lb. (or say 6,000 tons of 40 cubic feet measurement), being carried across the Pacific Ocean by steamers running in connection with the Canadian Pacific Railroad.—*L. & C. Express.*

TEA IN CEYLON.—A correspondent writes:—It is an interesting fact, that wherever the experiment of tea cultivation has been ventured upon in the Galle district, it has answered the planters best expectations, and the growth of the bushes on some of the estates here has been pronounced to be equally good as in places better favored with conditions of soil and climate. At the local sales of tea in the Colombo market, last month, I was shown the account sales rendered by the firm of Messrs. Forbes & Walker, from which it appears that a single native proprietor in Galle had placed in the market 4,295 lb. of made tea. Nothing surprised me more than to be assured by this Sinhalese gentleman that the present entire cost of his manufacture does not exceed an average of 18 cents the lb. on the estate; and as some of these teas realized as much as 68 cents per lb., at the sale in question, it must surely leave a large margin of profit, clear of all expenses.—*Indian Agriculturist.*

CEYLON UP-COUNTRY PLANTING REPORT.

MATALE SHOW—CACAO—TOBACCO—COFFEE—A LADY ON
TEA FACTORIES—THE GLASGOW EXHIBITION.

2nd October 1888.

The SHOW at MATALE was not by any means so good as the one held last year. There was the same defect in the buildings, the roofs too low, and, as a result, the place was dark, and the exhibits suffered in consequence. The native workmen, who were to show their skill to all-comers, were a screaming farce. They would do nothing without being "tipped," and early in the day were hopelessly demoralized, or hopelessly lazy. The present of a quarter of a rupee—half what was paid to see the whole Show—only resulted in a stirring of their lethargy; there was really no work done. One fellow who did weaving carried off the palm for listlessness. He would, when fee'd, condescend to exhibit his skill for a minute or two, and immediately after leave his loom for his mat. He was too enervated to get upon his feet when he sought repose after his hard toil; he slithered along with a crab-like motion, his bottom never more than two inches from the ground at any time. I understood he came from the wilds of Laggala, but no civilized trades-unionist that ever I saw, or heard of, could have matched him in his advanced notions of what was a fair day's work, or the remuneration due thereto.

There was another genius among the band of art workers who certainly deserves a place here. It was the artist who painted the pottery. He had before him a series of small pots filled with paint and had an unfinished chatty in his hand. When you stopped to see his methods, he would dip his brush into the paint, make as if he were going to begin, and look at you beseechingly. I offered nothing in response to that silent appeal, and slowly the chatty was laid down and the brush too. I waited for a little, hoping to see something of Sinhalese free-hand drawing, but no: he too evidently had his price, and I had to come away without seeing what I wanted.

There was about the whole band of art workers a weary indolent air, and if the Show Committee had intended to exhibit specimens of Sinhalese apathy, they could not have done it better than they did with any amount of trying.

Then the Refreshment arrangements were deplorable. You could get nothing almost you wanted, and when it did come you had got so tired waiting, and everything was in such a hopeless muddle, that there was no pleasure whatever. Every ten or fifteen minutes a man was seen flying across the grounds with a teapot in one hand and a jug in the other. I don't know if he were the head boss or not, but he did his best all but single-handed to satisfy the demands of a tired and thirsty public. He was a handy fellow, not easily put out, and had many resources. A dozen cups or so is, I think, an excessive estimate of the crockery that was provided by the purveyor, and you had to wait till somebody was done, before you were supplied with china. As there was no water about to wash the cups in, the handy man above-mentioned picked up your teapot, poured a little tea into the cup, swirled it about, threw the swirlings away, and you were free to begin. Had we been a band of intemperate passengers, the arrangements might have been tolerated; but after such a season of transport about the refreshment to be provided, and such a powerful Committee on the Show Executive, there was wretched mismanagement somewhere to have allowed the refreshment department to drift as it did.

On the whole I think there was disappointment with the Show, and although the Matale folk showed great pluck in attempting a yearly Exhibition, yet it was somewhat manifest that the strength of the place was overtaxed. When the competition for the best dressed Tamil was being spoken of, it was regretted that no prize had been thought of for the worst old hat a planter could produce. It was believed that such a prize would have brought many into the field, which modesty would otherwise keep out. With his working beaver the modest one would feel as if his foot were on his native heath, and he only too proud to compete.

CACAO in Dumbura has, I hear, suffered very severely from the drought, and the estimates are woefully short of what at one time were thought of. Other parts which had more rain are doing better, but with all I question much if the crop will over the planting districts be up to middling. The trees, however, still go on blossoming: the wealth of flower thrown out this year has simply been amazing.

Said the young TOBACCO planter to the older one, who prides himself on his knowledge, but would die rather than impart it, "What's the proper colour of tobacco when it's cured?" "The proper colour of cured tobacco's" reiterates the knowing one, there are thirty different colours!" And the inquirer has to go elsewhere, or be satisfied with that.

A lady from the lowcountry was on a visit to the hills. Seeing a tea factory in the course of erection with two rows of high pillars standing, she said she was surprised that they should want so many chimneys!

COFFEE is beginning to ripen, and in spite of the drought we have had, it does not seem yet as if there would be so much blackening at the points of the branches as usual. The beans, too, although perhaps smaller than ordinary, are quite full, the light being a very small item indeed. The bug too is very little about, and the leaf disease which was raging so badly a month ago has passed, leaving many bare trees, but still a hope of the crop ripening spite of the leafless condition of the branches.

The Weather is bright again, and all signs of the N.-E. monsoon have disappeared. Wind strong at times from the old quarter.

What will the harvest be?

The dimensions of the expected surplus at the close of the big Glasgow Show have been much canvassed of late. Judging by mere numbers, one should expect a substantial balance on the right side. But these numbers, apart from their financial equivalent, are apt to tell a too flattering and deceptive tale. It is rather anomalous that Glasgow should be so far in front of Manchester in admission numbers, and at the same time should be so far behind in admission money. At the end of four months our drawings are not one-half of the total Manchester "gate" of £143,000. Our four months' receipts at the turnstiles have only reached £70,000 as against Manchester's £96,000. Manchester had the grand income from all sources of £268,000, and a surplus of £43,000. Those who think that Glasgow can approach or exceed that surplus, are, I'm afraid, imagining a vain thing. The extraordinary devotedness of the season-ticket holders in hastening so repeatedly to Kelvingrove may prove an upsetting factor in surplus calculations.—*The Field*, P. 111.

MADAGASCAR TEA.—Mr. J. Andrianise, of Antananarivo, Madagascar, has successfully prepared for consumption a parcel of the first tea grown in the island. The aroma and flavour of the product are said to be so excellent as to encourage every attention being paid to the propagation of the shrub.—*Charity and Progress*, Sept. 5th.

Correspondence

To the Editor.

OUR CINCHONA BARK INDUSTRY.

London, 14th Sept. 1888.

DEAR SIR,—Your valuable editorial under the above heading has only this day come under my eyes in the *Tropical Agriculturist*. Your figures appear to me to be most valuable, because most practical. Whether Ceylon bark be likely to average so high a test as that at which you put it, or whether in all their other details your figures are likely to be in detail borne out by facts, are doubts incidental to the fact of your figures being a forecast and as such only intended to give very approximative information.

Roughly speaking, however, you lead us and lead us correctly to expect a 50 per cent increase during the next four years in the production of quinine in the bark and a 30 per cent increase in the total amount of quinine required for consumption, and you show that at the end of four years we are likely to find consumption ahead of production ~~it~~—but here the ~~it~~ comes in—if your hope should be realized: “but there is against this the probability of new uses being found for quinine, its gradual supersession of opium, &c., &c.”

You have without doubt hit the right nail hard on the head. The consumption of quinine must be fostered and facilitated, and the only way to foster the sale of any article on a large scale is to make it easily accessible to the million at a price which the million can afford to pay.

There is no reason but one why the consumption of quinine should not soon be 20 millions of ounces a year and rapidly increasing from that figure, and that one reason is that the people who want it most, cannot now get it at all.

Denizens of temperate climate or emigrants earning good wages can buy quinine. The Indian native earning a few annas a day, the Chinaman earning his few cash, cannot buy quinine; if they could the consumption would soon begin to multiply itself.

As those who are interested in this matter on a large scale do not seem to push the sale, I am doing my best in this direction, small as that best is, and I enclose you a pamphlet descriptive of my “penny quinine,” and send you by sample post a few boxes of the pills.

When quinine shall have been made known and available to those for whom it was intended, we shall hear less of distress in the bark trade whether it be in the growing, the selling, or the manufacturing part of it.

Then and then only we shall return to a solid improvement in prices so large, that it shall surprise those who think that rings, syndicates, and other artificial contrivances can help a trade and who are even now finding how little such things can do for them, but so long as high retail prices of quinine shall stand in the way of largely increased consumption, so long shall we continue anxiously to watch whether Java send a million or two more lb. of richer bark, or Ceylon a million or so less lb. of poorer bark.

The operator of last November missed his chance of slipping out between the showers; of realizing for himself a fine profit, and of giving the trade a fillip before Java should become a really serious factor in the question. Now he must bear the burden for the market, and we must turn for relief to the only legitimate source of revival which as you point out, is to be found in an increased Consumption of Quinine.—Your faithfully,

RIVERS HICKS.

THE DISCUSSION ON TEA IN THE LONDON STANDARD.

LONDON, 14th Sept. 1888.

SIR,—I propose leaving Brindisi on the 12th November in the P. & O. steamer “Massilia” and hope to remain in Ceylon till the mail following which, as it will be carried in the “Oceana,” will not allow more than 12 clear days at the most. I send you cuttings from the *Standard* upon “The Tea We Drink,” and think that the leading article and the letters which it has brought forth are a good sign that attention is being directed to the wretched quality of tea that so many of those well-to-do are content to drink day after day.—Hoping to see you soon, believe me, faithfully,

JOHN HUGHES.

THE TEA WE DRINK.

TO THE EDITOR OF THE “STANDARD.”

35, Eastcheap, E. C., Sept. 10th.

SIR,—Your well-timed Leading Article on the Tea we drink will doubtless prove of distinct advantage, by opening the eyes of the public to the trash which is too often consumed for Tea.

As you suggest, the stuff mentioned by your Correspondent at one shilling per lb. is a price so low that nothing but rubbish can be expected. But at two shillings per lb. excellent Tea can be supplied, and is supplied by all grocers worthy of the name. I do not mean Tea possessing in its own degree the merits of “Lafitte, one hundred and thirty shilling the dozen,” but Tea which, for this comparison, might be placed against claret at half one hundred and thirty shillings.

The trouble is, as you suggest, “the cutting competition in Mincing-lane,” which has debased the public taste, and caused a demand for low-priced Tea, quite irrespective of quality. Certain Wholesale Tea Dealers of Mincing-lane are engaged in retail trade, under assumed names, and in their competition with each other and the grocers, their main object seem to have been to sell the lowest possible priced Tea. Who has not seen at railway stations the notice, that by buying a certain firm’s Tea at one shilling and threepence per lb. the public save one shilling per lb.? This tea, for an extra threepence per lb., is delivered, post paid in the country; but the postage on the Tea, and the invoice and receipt, which are sent to customers, cost fourpence-halfpenny; thus the Tea is retailed at one shilling and three-halfpence per lb. and has to bear its share of enormous advertising expenses.

Another large firm, whose quotations commence from one shilling and fourpence per lb. announce to the public that they sell “at a bare commission on the prices actually paid at the place of growth.” But everyone, however unacquainted with the trade, will see, on reflection, that the price of this Tea, somehow or other, has to cover cost of freight to England, dock and warehouse charges, expenses of distribution, greatly swollen by heavy advertising, as well as the Custom’s duty of sixpence per lb.

The evil does not end here. Consumers see at every turn these low-priced offerings of common Tea, and so the grocer is compelled to devote his attention to price, rather than to quality, with the result that the public taste in the matter of Tea becomes more depraved every year.—I am, sir your obedient servant,

JOHN HENRY BETTS.

Enfield, September 10th.

SIR,—I find from a note-book of mine that your remarks in *The Standard* of today on the purity of Tea in Dr. Johnson’s time were slightly optimistic. In 1777 an Act was required to prohibit counterfeiting Tea with sloe, liquorice, ash, or elder leaves, by imposing a penalty of five pounds for every pound sold or found in possession.

In 1784, the year when Johnson finally bade farewell to the Teapot, the accountant of the East India Company estimated that over twelve million pound a year of the leaf were either counterfeited or smug

gled in Great Britain. Hence the duty was lowered, and a house-tax imposed instead.—I am, sir, your obedient servant,
ARCHIBALD WEIR.

Sir,—Very few of your earlier correspondents would appear to be actually in the swim of the tea trade. It is an extraordinary but a well-authenticated fact, that the British public, taken as a whole, know little or nothing about tea, or the manufacture thereof; if anything less than they do about soap. Hence the reason why tea and soap should be the two favourite articles for advertisers to puff.

Up to a few years ago the tea trade was a fairly profitable one to all concerned in it. Importers thrived on it, brokers lived out of it, and dealers and grocers both made their profits, without having to descend to any of the petty tricks now in vogue. All this is a thing of the past, and at the present time importers pander to the popular inquiry for cheap tea by bringing in cargo after cargo of the commonest stuff that the Hongs of China can produce, and for one half-chest of good tea sold, there are fifty of what your correspondent, "Mining Lane," so much enjoyed at 4½d per lb.

The extraordinary strides made by Ceylon tea, during the last few years show that a proportion of the tea drinkers of England can still appreciate a really good article, and, as the finest of these teas resemble much in purity and character the old-fashioned Monings of years ago, even the Chinaman, dense as he appears to be to his own interests, must see how much he has lost by sacrificing quality to quantity.

The very commonness of the bulk of China tea imported has been the making of Indian tea, as a good, rough-drinking mixture can be got by blending a little of the latter with a lot of the former; and as clean China tea can now be bought at 5d per lb. and strong rasping Indian at 10d per lb., it is easy to see that a compound of even half-and-half must pay well at the general retail price of 1s 8d to 1s 10d.

As regards the intermediate profits between producer and consumer, it is doubtful if they can be much lessened; and, of course, the advertising statements, "Direct from the gardens," &c., must be taken for what they are worth. They do not impose on any one who is "in the know."

Tea, as a rule, passes through five hands. The importer gives it to a first hand broker; he probably, places it, with a second hand, or "buying over" broker, who in turn divides it out between his *clientèle* of dealers at one-half per cent commission; the dealers send it again to the grocers, or packers and blenders, as the case may be, and the latter, as a rule, are the people who advertise, for the benefit of the gullible public, that they buy direct from the gardens.

The consumer is as far off from the grower as ever he was, and it is only the low price of tea and the power of modern advertising that lull him into the belief that he buys at a "bare commission." I am, sir, your obedient servant,
G. M. ROMERS.

14, Mining-lane, S. pt. 130b.

Sir,—It is to be hoped that your able leading article on the above, together with the numerous letters that it has called forth, may induce the public to take a little more trouble in the selection of their Tea. What is required is a better appreciation of the flavour of really good Tea; the actual price per pound is another matter, and depends upon the increased production and greater competition.

The consumer should have the opportunity of purchasing genuine Ceylon, Indian, or China Tea separately, and afterwards blend them as he may wish, instead of buying a special mixture at so much per pound, as advertised. If this were possible, those who like a strong, astringent Tea, with a large amount of tannin, could purchase Indian leaf from Assam, a variety which, I believe, is admirably adapted for general use, or in a hot climate; while, on the other hand, persons of weak digestion could select Ceylon or the better quality of China Tea, which combines a fine flavour with much less of the objectionable tannin.

It may not be generally known that the proportion of tannin present in Tea varies considerably. In strong Assam, I have found as much as 15 to 17 per cent, while in Ceylon and some kinds of China there is not more than half this quantity; and in one sample of Ceylon, grown at an elevation of 6,000 ft., the amount of tannin was only 6 per cent. Indeed, the elevation seems to have a great deal to do with the proportion of tannin, the higher-grown Tea containing the least.

The great demand for genuine Ceylon Tea is a distinctly hopeful sign of an improvement in the public taste; and I was much struck, during a recent visit to the Glasgow Exhibition with the fact that as early as one o'clock in the day the little Ceylon Tea-house was crowded with people, while the larger and certainly better appointed Indian House was almost empty. The character of Ceylon Tea owes much to its soil and climate, but also a great deal to the skill and improved machinery which the energy of the planters has introduced into the manufacture.

In 1877, when I first visited the island, and made a tour through the planting districts, very little Tea was made, and for some years the quality with a few exceptions, was poor in flavour, in consequence of a want of technical knowledge in the process of manufacture. Since then, however, the fame of Ceylon Tea has increased by leaps and bounds, and in my coming visit next December I expect to see wonderful changes in the general prosperity of the estates, in consequence of this new industry.

In conclusion, I would warn the public against spurious Ceylon Tea, which consists simply of inferior China and some Indian. Genuine Ceylon Tea should have a fine flavour, and be free from that rough taste peculiar to strong Assam Tea.—I am, Sir, your obedient servant,
JOHN HUGHES, F.C.S.

Analytical Laboratory, 79, Mark-lane, Sept. 12th.

Sir,—As a practical Tea grower, may I say a few words with regard to very cheap Tea? I can only judge by my own experience of what I can afford to sell at. With the exception of Dust, a Tea Planter must average a shilling per pound all round for his Tea sold by auction in Mining-lane, to make but a small profit, even if his garden be well placed—that is not too far from a shipping port.

For this shilling per pound he has to grow the Tea, pluck it, wither it, roll it, ferment it, fire it, and buy Tea chests, Tea lead, nails, &c. Also pay carriage to nearest port, pay freight, insurance, dock charges, merchant's commission, and brokerage. Now, Sir, so far we have got a drinkable Tea at a shilling; let me ask if your readers know what has to be added to that amount ere it reach the consumer's cup?

First of all, there is the duty of 6d per pound, which brings it at once to 1s 6d. Then there is the whole sale dealer's profit, carriage to the grocer, and last, but not always least, the grocer's profit; and I leave you to judge how much under two shillings a pound it is possible for the public to buy decent Tea at. How grocers can sell Tea at one shilling, which must have had sixpence per pound duty paid on it, besides all the numerous expenses I have before mentioned, is a riddle I cannot solve.

I am glad to say I have only once seen Tea which was sold at one shilling, and I never in my life smelt such stuff. It certainly had never been plucked off the bush we planters are accustomed to know by the name of Tea. There is no doubt that the greater part of the public, not knowing that sixpence per pound duty has to be paid on all Teas, good or bad, think that fair Tea can be bought at these prices; and all I want them to know is that there is this duty to pay, even on the worst of Tea, and I feel quite sure they will then understand the reason why genuine Teas cannot be sold at these low prices.—I am, Sir, your obedient servant,
FERGIE.

September 12th.

Sept. 11th.

Sir,—The public and the trade should thank you heartily for so generously opening your columns for

the ventilation of the above subject. Tea is now so generally used in this country, that its quality is of national importance. We have long and earnestly protested against the fatal rush after "Tea for price," and welcome the sound observations in your admirable leading article.

It is a well-known fact that (so called) cheap tea is very dear in the end, for more is needed to be used, and no pleasure is derived from the cup which ought to cheer. Your correspondent "Mincing Lane's" lady friend, who characterises the 4½d. sample as "very good," confirms Mr. Betts's statement, that by reason of the puffing of these very common teas, "the public taste in the matter of tea is becoming depraved." As wholesale dealers in tea, we are grieved to see so many really good, wholesome, and pleasant-drinking teas at moderate prices neglected largely for the nasty stuff which only irritates the drinker, maligns a noble industry, and lands the dealer in it in loss. Your correspondent "Expert" unintentionally lets a flood of light upon the quality of this rubbish, when he says, "The teas fetch (regardless of prime cost) what buyers consider them worth in open competition." If this estimate of value reaches 4½d., it speak volumes.

We are getting now some very excellent teas from Ceylon, and some of the milder-drinking sorts of Indian tea are pleasant enough; but for them no such quotations as those referred to are known. Fine to finest Darjeelings—teas to dream about—fetch from 2s 6d to 3s 6d in bond, and are cheap at that, as an article of diet.—I am, sir, your obedient servant, JOHN WADE.

St. Dunstan's House, E. C.

Sir,—Your Correspondent "Mincing Lane" finishes up his letter, in *The Standard* of today, by remarking that, "whether Ceylon will keep up its character, or whether the soil will give out, and thus repeat the sad experience many had with Coffee, remains to be seen." It appears to me a pity that, in a discussion on the quality of Tea supplied to the public, an attempt should be made to throw doubt on the permanence of an important industry.

Let me assure him that the soil of Ceylon is not at all likely to "give out." The Tea plant is a deep feeder, with a long tap root, which touches a soil that may be called virgin, and of which there is a great depth all through the Tea districts of the Island; and as to quality, that will improve as the bushes mature. The finest Tea comes from the oldest gardens.

There is, I believe, a marked similarity between Ceylon Tea and the fine qualities of China which used to reach this country; and it is owing to this that Ceylon is in such demand. But "Mincing-lane" is wrong in stating that there has been a decided reaction lately in favour of the two Teas—it may be so in the case of China—but Ceylon has been in favour all along.—I am, sir, your obedient servant, C. S.
September 11th.

Sir,—Although it is quite right that the attention of the public should be drawn to the fact that the common tea they buy at one shilling at the shops, is very dear at the price, it must at the same time be remembered that it is the severe competition that has brought the price down so low; the quality is just the same now as it was ten years ago, when the wholesale merchants had to pay one shilling per pound on the market for the same grade of tea.

But, sir, the shilling bait is only a sprat to catch a mackerel, as the public pay much more for their tea than that. For the last four years I have taken great interest in the tea imported from Ceylon, and have been the means of introducing largely favourite brands which have met with much appreciation. Ceylons are all good quality, similar to what we were used to years ago in the era of the old clipper time. The average price fetched in public sale for Ceylon Tea is one shilling and a penny to one shilling and fivepence. The public can rely with safety upon the purity of Ceylon Tea, as it is grown and prepared by Englishmen.—I am, sir, your obedient servant,

BUNGALOW.

Eastcheap, September 11th.

Sir,—As a tea planter, and, consequently, much interested in the subject, I write to protest against the vile rubbish now being sold in London, and all over the country, as tea. I got a sample from a country town, a short time ago, which the grocer was selling at 1s per lb., and for which he informed me he gave 4½d in bond. He then has to pay 6d per lb. duty, and carriage, possibly another farthing. This leaves him a profit of only a penny per lb. Now, this tea has been sold to him by a London merchant at certainly not less than a halfpenny per lb. profit, more probably three-farthings, or a penny; say a halfpenny. We thus have this tea sold in Mincing-lane at 4½ per lb.; some is sold at a lower figure even than that. Out of this, the grower has to pay an export duty, in China, of not less than 1½d per lb. leaving 2½d to grow the tea, get a profit, pay freight, insurance (if he insures), warehousing, and other expenses in England, and brokers' charges for sale by auction.

Let the public ask themselves whether this can be done, so that they can get a tea fit for a human being to drink. Can it even be done at 1s 3d or 1s 4d per lb. retail, for it must be remembered that the more a grocer gives for tea, the more profit he expects to get out of it? This varies much in different localities, ranging from 1d and 4d per lb. up to 9d and 1s. I tried the tea in question, and am astonished that people can be found to drink such stuff. Before infusion it smelt like shoe-leather; after infusion it had a strong flavour of tallow, and the infused leaves had a most unpleasant smell. The poorest class, probably, buy this tea. They are mistaken, if they think it an economy. Half the amount of good tea would make a stronger drink, and, certainly, a more palatable one. It is well known that spent leaves—that is, leaves once used—are dried and rolled, mixed with a little fresh leaf, and resold; and I understand, from men in the trade, that stuff is shipped which is not tea at all. This has been proved by analysis. I do not believe that two-thirds of the public are aware that 6d per lb. has to be paid on all tea in England, good or bad.

My object in writing this letter is to warn people against the vile stuff sold at low prices. You may say that a demand creates a supply; but I cannot think that the public are acquainted with the few figures I place before them. I think I may claim that the subject is one that requires ventilation. If you, sir, should think the same, pray publish this letter.—I am sir, your obedient servant,
B. M.

September 7th.

A correspondent, whose letter we print in another column, protests against certain rubbish which is being extensively sold in this country under the name of Tea. It is retailed at one shilling the pound; so that, after paying export duty in China, import duty in England, and allowing the most moderate profit to the wholesale merchant and the grocer, there remains no more than twopence three-farthings to meet the cost of growing the stuff, to reimburse the planter for his expenditure of capital and labour, and to pay freight, insurance, and other expenses, including the broker's commission for selling it at auction. We are, therefore, not surprised to learn that the leaves, before infusion, "smelt like shoe leather," and, after infusion, had a "strong flavour of tallow," plus "a most unpleasant smell," which, if worse than that of last year's tallow, must have been a very nasty odour indeed. Our Correspondent does well to be angry, though whether his financial analysis of this unwholesome product of the Flowery Land will have any practical result, is very doubtful. The Adulteration Act does not apply to it. In every respect it may be unfit for human food; and it is certain that no one would think of knowingly drinking such an unattractive beverage. But, botanically, the material consists of the leaves of *Thea sinensis*. Indeed, it is questionable whether any other herb at all like it is so much cheaper that it is worth seeking out for the purpose of adulteration, though endless drugs are employed to "face" these inferior Tea leaves, and impart to them a semblance of those native merits which either they never possessed,

or with which they have long since parted. Hence, the administrators of the law are disinclined to interfere with the traffic in this vile herb, which, if at all like that of 1678, justifies the lament of Mr. Secretary Coventry, that nations were growing so "wicked" as to have "the filthy custom of calling for Tea, instead of pipes and bottles after dinner." Tea which costs, at first hand, less than twopence a pound, needs no tavern bush to proclaim its quality. But, though it is, happily, an "exceptional brand," there is plenty, at a much higher price, which is not much better. The cup into which it enters may not inebriate, but a knowledge of its contents can scarcely cheer. Nevertheless, hundreds of the most lavish hosts, who pour out Lafite at one hundred and thirty shillings the dozen, and who would scorn to offer a bottle with even a suspicion of corkedness, will, half an hour later, themselves drink, and, without a thought that they are not keeping up the character they assumed earlier in the evening, ask their guests to drink "fine flavoured Bohea" at half a crown the pound. This, no doubt, may be very superior to the shilling tea over which our correspondent so justly waxed wrath, yet it is not fit for a house in which wine at fifteen shillings the bottle is consumed. No host in Russia—China or Japan may be taken for granted—would dream of drinking Tea of this kind, even though the claret might bear a humbler label than that of English dinner-giver; but even when ten shillings is paid for a pound of overland "Thé" from Kiakhta, the cost of an entertainment is not very appreciably increased by this extravagance.

The truth is that in drinking cheap tea we err more in ignorance than out of negligence. Accustomed to the low-priced article which the cutting competition in Mincing-lane has put before us, few men think or know that there exists, even in China, growths worth forty or fifty shillings the pound, and that in the famous district of Uji, in Japan, there are some valued at more than sixty shillings the pound. Of course, we may well believe that there is not a great deal of this "chop" in the Yokohama market. However ten, twelve, and even fifteen shillings, is by no means an uncommon retail price in Moscow and St. Petersburg; and in London, brands quite as high, and as well worth the money, may be obtained, though, perhaps, not in the shops which profess to sell "Flowerly pekoe" at one and fourpence the pound. But London dealers know that it is useless to import such high-priced teas in any quantity, for not one person out of ten thousand would dream of paying the value put upon them. They have been educated into knowing that '51 port is not to be had for thirty shillings the dozen; but they readily swallow the fiction which affirms that no better tea need be drunk than "our Young Hyson" at eighteen-pence, or "our superb Souchong" at twice the money. Even Russia is getting corrupted by the cheaper teas imported by sea; and there are rising up economists who, like M. Tegoborski, are not slow to affirm that the legend regarding the superior quality of Caravan tea is unsupported by actual facts. China has, however, another tale to tell. Year after year, her trade in tea has been so much cut into by India, Ceylon, and Java, that the Government has become thoroughly alarmed. Fortunes are no longer acquired in the business, and a bare livelihood is getting difficult. Between 1881 and 1887, the export had decreased by about twenty-six million pounds; while that of India and Ceylon had increased by thirty-seven million pounds; and this year is expected to show a still greater disparity. Instead of trying to meet the rivalry, by imitating the English growers in their departure from the old, conventional methods of preparing the leaves, the Chinese planters and cultivators have endeavoured to make both one meet by further and further sophisticating their wares, with the result that they are not cheap, and are decidedly nasty. The notable exceptions are that the better cultivated, better cultivated, better cured, better picked, more honestly sold, and yet lower priced teas of our eastern Empire are rapidly supplanting those of China in the market, now that the consumer has learned to distinguish good from evil, and to abandon the arbitrary

taste he had acquired for the Sinetic article. Already, Japan has stolen half of the Chinese trade in green tea. Before long, unless the growers who, until twenty or thirty years ago, had a practical monopoly of the business, turn over an entirely new leaf, Ceylon and India will have absorbed their once enormous, and still important, commerce in black tea.

The beverage with which hardened tea drinkers, like Dr. Johnson, "amused the evening, solaced the midnight, and welcomed the morning," was not quite the herb in which so many of his countryfolk find a moderate degree of comfort. At eight or nine shillings the pound it was reasonably pure, and, though lacking something in nicety of preparation, was better than the hastily-cured stuff which is despatched to meet the demand for a sound family tea" at one and threepence the pound. The adulteration came later. Then it was that paddy husks, and various other leaves, faced with clay, soapstone, catechu, and black lead, supplied the lack of the unadulterated herb. What was advertised as "Fine Morning Congou" was known in the trade as "Ma-loo Mixture," and in China by the frank title of "Lie Tea." It consisted of the sweepings of the "Godowns," of the re-dried leaves of exhausted tea, much of which had become putrid, and of other rubbish, which an eye-witness described as lying in heaps in Shanghai, with dogs and pigs trampling over it. Nor was "Lie Tea" making unknown on this side of the ocean. Several establishments were reported to the Board of Inland Revenue as engaged in the business of collecting from hotels, coffee-houses, and elsewhere, exhausted leaves, re-drying them, and facing them with rose-pink and black lead. Others contrived to make the leaves of the sloe, hawthorn, peach, willow, beech, plane, and other plants do duty, until it was next to impossible to obtain a perfectly pure specimen of a green or fancy tea. Of late years, we believe, there has been comparatively little adulteration, either here or on the other side. The analyst has been too much for the rogues. Moreover, the latter have learnt that there are more ways of cheating the public than by selling them sloe leaves for tea, and hay for tobacco. Instead of mixing up strange herbs with the real ones they prepare the latter in a cheap and careless fashion, and toss into the "chops" any and all growths. They no longer devote the care, money, and time which the English growers do to the selection of the shoots in strict accordance with their future gradation in teas. The result is a kind of unpoetical justice. After half poisoning the people for years, and corrupting the public taste until it is almost beyond redemption, their sin has found them out at last. Their malpractices have been brought to light, and they are now seeing their business pass into the hands of men who early learnt the lesson which teaches that honesty is the best policy.

Sir,—The following figures, compiled from Official Returns, show the home consumption of the different growths during the three years ending 31st May, 1886, 1887, and 1888:—

	INDIAN. Pounds.	CEYLON. Pounds.	CHINA. Pounds.
1886 ..	59½ millions	.. 3½ ..	99
1887 ..	74 7½ ..	96
1888 ..	81 12 ..	84

These statistics, coupled with the fact that the August home consumption of China Tea was 1½ million pounds less than 1887, upset the theory of a reaction in its favour. It is surprising that any one hailing from Mincing-lane should be so misinformed as to broach such a theory.

The verdict of the fact in favour of British grown Tea—when merely reckoned the optimum consumption—is the more emphatic, because the cheapness of China tea would enable the trader to make a larger profit on his sale, if he could sell it against competitors who are selling Indian or Ceylon.

In order to ascertain why China Teas are being pushed out of consumption, it is only necessary to obtain half an ounce of Indian or Ceylon, and of China of equal market value, infuse each in a pint of boiling water for five minutes, pour off the infusion, and re-

fill the pot. It will be found that the former will give a good second brew, while the China will not.

The fact is, most Indian and Ceylon Teas are so strong, that about half the quantity required when China is used will suffice.

The "tannin" bogey is an old one, and need scare no one. The infinitesimal dose contained in a properly made cup of tea—i.e., brewed for five minutes only—is rather wholesome astringent. Tea-tasters, at any rate, suffer less from sore throat than most people; and many of them are renowned for their vocal accomplishments. The analyst, moreover, omitted to mention the larger percentage of theine and nitrogen which Indian Tea contains.

On the general question of price, let me say how absurd it is to use a cheap and nasty common Tea, when, even at the rate of 3s. per lb., a cup costs barely one-third of a penny. The canny Scot and the shrewd Irish man know this; consequently, they take the bulk of the choice Tea produced, leaving the trash to be consumed by the unenlightened Englishman.

If those who think they are economising by using the Teas retailed under 2s. per lb. were to procure some really fine Tea from one of the respectable firms, such as Cooper, or Ridgway, and compare results, they would soon discover their mistake.—I am, Sir, your obedient servant,
HARD FACTS.
Sept. 14th.

Sir,—I am a Tea-planter and Tea-taster of seventeen years' experience, and I read with great interest your article in the *Standard* of the 10th inst. on the "Tea we drink." I agree entirely with "B. M.'s" remarks on the same subject. My object in writing to you, sir, is to protest against, not only the vile stuff sold as tea to the public, but against the exorbitant prices charged for cups of tea at hotels, restaurants, country inns, railway stations, and several other places.

Surely, sir, with tea selling at such low prices, it is monstrous to ask 4d and 6d for a cup. But this is far too common. The cup of tea at a railway station, for instance, is heavily handicapped against a glass of beer, for which only 2d is asked, and which can be had fairly good, and at once, whereas the former is, nine times out of ten, more than double the cost, wishy-washy, and often not ready.

Yesterday I was driven from the Lizard to Falmouth. The brake stopped half-way at a country hotel, and there I had to pay 9d for two cups of tea, which were undrinkable, and for which I had to wait ten minutes, whereas I could have had two glasses of beer for 2d (1d the glass), and without waiting a minute. This is merely an instance of what is the rule all over the country. There is no reason, Sir, why tea should not be sold at 2d. or even 1d. the cup, and decent tea too, leaving a decent profit.—I am, sir, your obedient servant,
G. W. D.

Garrans, near Grampound, Sept. 13th.

Sir,—A word in answer to one point in "Mercury's" letter in the *Standard* of today—viz., as to the deterioration of Ceylon tea when opened. Having had several boxes, 50 lb. and 25 lb., open for various periods, I can give this statement a most emphatic denial, the tea remaining as good as at first, and never losing its aroma; but then what I drink is real Ceylon, shipped straight from the factory, and in no way interfered with. Ceylon tea should not be used until it is quite three months old. It requires the mellowing influence of time.—I am, sir, your obedient servant,
EXPERIENCE.

Sir,—With reference to the discussion upon the Tea we drink, may I be allowed to say that, apart altogether from the question of good or bad Tea, there are one or two reasons why the beverage in question, as generally prepared in England, is not so satisfactory as it might be?

In the first place, the repeated addition of boiling water after the Tea has been allowed to stand some time extracts a not inconsiderable amount of tannin

This is, in my judgment, not only unpleasant, but objectionable, and I think that the practice of frequently filling up the teapot should be abandoned.

Secondly, the addition of a minute quantity of milk, as is usually done, is, in my opinion, a mistake. I believe that a few drops of lemon juice are infinitely preferable; but, if milk must be used—and it certainly mellows and softens the Tea to some extent, though, at the same time, it does away with most of the aroma, and renders the fluid greasy—the proportion should be much greater, say, from a quarter to a third of the total quantity.

It is, perhaps, hardly necessary to add that the water should be boiling, and that soft water is far superior to hard.

Finally, it may be mentioned, that the very frequent consumption of a semi-boiling and somewhat astringent fluid can hardly be regarded as calculated to assist digestion.
H. S. CARPENTER.

London, September 14.

Sir,—Will you allow me, through your columns, to point out to "Souchong" and others interested in the subject, that any person—be he importer, broker, or retail grocer—who sells, or offers for sale, or causes to be offered for sale, Tea under the titles of "First Crop Congou," "Finest Kaisow," or "Finest Moning," &c., which is not properly described under these titles, or who makes use of a trade description, directly or indirectly false in any respect, renders him or her self liable for a term of imprisonment with hard labour for two years, under the Merchandise Marks Act, 1857, which came into operation a few months ago.

The onus of proof is thrown upon the Defendant. This Act has already been put in force in other trades with most salutary effect, and there remains no reason why the dishonest Tea dealer should continue to defraud the public and get off scot free. J. E. E. J.

London, September 14.

Sir,—I cannot allow the letter of "Taster and Blender" to go unanswered as to the branding of Teas in packets being a guarantee of their quality. What does he say, for instance, about one of the first houses in London, now supplying grocers in the country with their packeted tea at 1s. 4d. per lb.? I believe that as great frauds are perpetrated by these means as by any other, and when "Taster and Blender" brings forward wine and cigars to support his argument, he brings forward the very worst champions he could have picked out. With regard to Ceylon Tea particularly, we find the country flooded with Teas in packets, bearing names of estates, in most cases fictitious. As a matter of fact, Ceylon planters do not put their Tea up in packets; and if people judge Ceylon Tea by these they are woefully mistaken. These are invariably made up in London.

I do not say they are all the same, but most contain a small amount of Ceylon Tea of a certain grade; the rest, some common rubbish. I was shown the other day by a grocer in the South of England, a quantity of showy labels, sent down to him by a London firm. These had the names of Ceylon estates, which I knew, on them, but with one letter in the name altered. The public may be certain that if they cannot trust a respectable man to sell them Ceylon Tea pure, loose, they do not insure getting such by buying it in packets with a fictitious estate name on it.

As a Ceylon planter, and, as such, of course, jealous of the reputation of the Tea which this sort of thing is doing much injury to, I ask you, sir, to publish this letter.
September 14.
B. M.

Sir,—Mr. Hughes' letter in your issue of the 12th instant is a fair and just tribute to an article that has become popular on its own merits. Since the public generally first had the opportunity of tasting pure Ceylon Tea at the Health Exhibition in 1884 the demand has kept pace with an enormously increasing supply, the imports in 1884 amounting to under 2,500,000 lb., whilst this year they are expected to reach 22,000,000 lb.

No effect is being spared in Ceylon to insure a continuance of popularity by keeping up the quality, and the public should, in its own interests, encourage, with its patronage, those firms whose Ceylon Tea is Ceylon Tea, and many of whom supply it much more nearly direct from the gardens than Mr. G. M. Roberts would lead you suppose. In conclusion, I would point out that Ceylon is British-grown Tea, and should, on that account (given equal value), be preferred to China.
September 11. Ceylon.

Sir,—Notwithstanding the opinion which is expressed by "J. E. E.-J.," in the letter contained in your issue of to-day, I am afraid that those who proceed under the Merchandise Marks Act, 1887, against the vendors of "cheap" Tea, will meet with disappointment. No doubt, in the case of fraudulent "garden marks" affixed to packages of Ceylon or Indian Tea, by the Act there is afforded, in addition to the procedure by which planters and importers can protect themselves, an excellent method of dealing with dishonest traders.

But, in the case of China Teas, an expert alone is able to distinguish a first from a second crop, or between many of the infinite number of varieties. And in every case the packages are marked under the direction of experts in China. So that, even were a Prosecutor able to prove that such "markings" as "finest," "choicest," "first crop," &c., were trade descriptions within the meaning of the Act, so long as the Defendant had confined himself to the generally sufficiently attractive description inscribed on the packages, he would have little difficulty in proving that he "had no reason to suspect the genuineness of the trade description," or had "otherwise acted innocently;" in either of which cases he could not be convicted.

Since, also, the Prosecutor must show the trade description to be "false in a material respect," he would be under considerable difficulty in obtaining a conviction in the case of Tea sold at a shilling, and described as "Kaisow" or "Moning." Whether a buyer of Tea at one shilling and fourpence per pound, duty paid—which, though so described, proves not to be the "finest first crop Moning"—is fairly entitled to consider himself swindled is, I venture to suggest, doubtful.
MALOO.

The Temple, September 17.

Sir,—The letter of your Correspondent "B. M." requires a reply from me, as he evidently did not read my letter as carefully as he should have done.

He says that he cannot allow my remarks to go unrebuked "as to the branding of Teas in packets being a guarantee of their quality." In advising the public to buy their Teas in packets, I gave these words, "Packed by respectable firms, bearing a trade mark, with a guarantee of quality." With regard to Ceylon Tea in packets, deception has undoubtedly been practised by some firms who cannot be called respectable, and the packets, even in such cases, contain no guarantee of quality, although they bear misleading statements, which tend to deceive the public. But because there are certain unprincipled men who do a hole-and-corner business in this way, your Correspondent must not cast a slur on Houses who are doing a large business in supplying grocers with packed Tea, which bear a guarantee of quality, and are labelled in conformity with the Merchandise Marks Act.

As to a certain House sending out packed Tea at one shilling and fourpence per pound, your Correspondent asks what I have to say to this? I recommended the public not to buy Tea in any shape or form at this price. The closing words of my letter were, "Let the public pay a fair price for their Tea, and select a brand which places their purchases in the Tea he refers to rather than those of these competitors."

Your Correspondent, "Anti-Monopolist," cannot be an expert, when he states that Tea only retains its aroma when kept in bulk. If he were a buyer and holder of Tea he would know how soon even the

best Teas, whether Indian, Ceylon, or China, lose their aroma, although kept in bulk; and that their value at "prompt day," if unsold, is very different to their cost three months previously.

On the other hand, I have tasted Tea which has been three and four months in 1 lb. packets, or in paper packets lined with damp-proof paper, which was as fresh at the end of this time as the day it was packed.
TASTER AND BLENDER.

London, September 17.

Sir,—I feel sure the Tea-drinking community will one and all thank you for allowing so much space in the *Standard* to be taken up, and such free opinions expressed, with reference to the Tea we drink. I feel compelled to remind your readers that any customer who purchases packet Tea may, if he believes he is defrauded in the article, take proceedings under the Merchandise Marks Act, which came into operation on the 1st January last.

Your Correspondent, in to-day's issue, makes a sweeping charge respecting Ceylon Tea in packets, which he says the country is flooded with, bearing names of estates in most cases fictitious. I can only say that he, being a planter, and jealous of the reputation of the trade, would be doing a public good, if he at once took proceedings under the before-mentioned Act, to bring the guilty parties to justice, and put a stop to the fierce competition now raging, which induces many to sell various descriptions of Teas under false names.

The article in *The Standard* has already been the means of clearing the windows of many large London shops of their immense posters, announcing "First Crop Congou," "Finest Kaisow," &c., at one shilling and fourpence.
EAST INDIAN.

Esher, Surrey, September 17.

Sir,—The summing up by Carlyle of the character of the British public as being "35,000,000, mostly fools," is again amply confirmed.

It costs close upon, if not quite, 2d. per lb. to pack Tea in these so-called "original lead packets." It stands to reason, this has to be paid for by the British public. This same British public may as well make up their minds to what (no matter what advertising packet Tea dealers may say) is an absolute fact. If they want to get the best value they can for their money, they must go to their grocer (who, I take it for granted, is a good one—at any rate most people have the choice between good and bad) and buy from him his ordinary Tea at 2s. or 2s. 6d. Below 2s. Tea cannot be good, and, certainly, there is not the least necessity to pay more than 2s. 5d.

Although interested in the packet trade, in honesty I must admit the British public have to pay through the nose for it.

It has let into the Tea trade, too, a lot of inexperienced noodles, who are incompetent to blend and pack their own Teas, and who before supplying their customers (who, by the bye, they make believe that the Tea is their own blending, &c.), pay yet another profit themselves to the firms they employ to blend and pack for them.
A. J. G. C.

September 18.

Sir,—I hope you will allow me to confute the statement of your Correspondent, "A. J. G. C.," that "Below 2s. Tea cannot be good."

I do not think he can have much knowledge of the Minging-lane market, or he would know that really good China Tea can be bought at the public auctions at 8s. 4. to 9s. 4. per lb. and very fine Ceylon and Darjeeling from 2s. to 1s., a duty of 6d. per lb. brings these prices to 1s. 2d. and 1s. 3d. in the case of China Teas, and 1s. 3d. to 1s. 6d. in that of Ceylons and Indians. Add 3d. per lb. profit to the retailer, which ought, in a large turnover, to be amply sufficient margin of profit for such a business, and you have the price of really good serviceable Tea from 1s. 6d. or, say 1s. 6s. to 1s. 6s. per lb.
ARTHUR HAWKINS.

London, September 19.

Sir,—My attention has been drawn to a statement made by one of your correspondents on "The Tea We Drink" as to the sale of tea, purporting to be from Ceylon, in packets bearing the names of estates which do not exist.

As agent in London for the Planters' Association of Ceylon, I recently received instructions from my principals to purchase such packets as seemed to bear a false description, and, if advisable, to institute proceedings against the under vendors the Merchandise Marks Act.

In the course of my inquiries, I have met with many packets of so-called Ceylon tea, on which the name of the estate or garden was given. In only one case was the name that of an existing Ceylon estate, and in that case, though the cover was labelled "Pure Ceylon Tea," it was admitted at once that only twenty-five per cent. of the tea was really from Ceylon. In one other case, however where the name of the estate was fictitious, the tea was all from Ceylon.

As a rule, no doubt, the teas exposed for sale in packets in this country as "Pure Ceylon" are mixed tea.

I am glad to have this opportunity of stating, through your columns, that the sole object of the Planters' Association of Ceylon in this matter is, if possible, to secure the observance of the law, and not in any way to interfere with any reasonable action on the part of dealers, grocers, and other distributors to meet the public taste. For it is fully recognised that it is on the regular trade channels that planters must, in the main, rely for the disposal of their produce.

Tea drinkers might do their share in helping us to attain the object in view, by taking some little trouble to ascertain that the tea they buy is really what it pretends to be.—I am, sir, your obedient servant,

WM. MARTIN LEAKE.

City Chambers, 65, Fenchurch-street, London,

IMPROVED AND PROFITABLE PADDY CULTIVATION.

Office of the Director of P. I.,
Colombo, 8th Oct. 1888.

SIR,—I have the honour to forward for your information an account of cultivation of paddy with the improved plough and by "planting out," received from the President of the Village Tribunal of the Gangaboda Pattu in the Matara district.

The particulars of cost and profit given are interesting, and it is to be observed that the President's experiment was one conducted independently of this department.—I remain, sir, your obedient servant,

H. W. GREEN,

Director.

Tihogoda, 28th August 1888.

H. W. Green, Esq., Director of Public Instruction.

Sir,—I beg to submit the following details in connection with the experimental cultivation I conducted during the last yala season.

The Uduwa tract is a very large expanse of paddy land usually cultivated during both the maha and the yala seasons of the year. An artificial channel affords all the necessary facilities for irrigating it. Some parts of the tract are very rich, but it is not so all throughout. The plot I selected for planting paddy is about one acre in extent, or, as the villagers would say, little more than one-third of an amunam or 18 kurnies in sowing extent. Its soil is admitted to be worse than the average in the tract.

This was ploughed with the new plough at the beginning of February and water was let in at once. It was ploughed again at the middle of March with the native plough. At the beginning of April a few buffaloes were drawn over it for a couple of hours. Five or six days after the dams were repaired, the ground was levelled, and a sprinkling of manure cow-dung was made. Paddy plants were then rooted out

from the nursery and left on the land for two days and the planting itself was done immediately after, a plant six inches apart.

I think I should state that the plants had two disadvantages at the outset, no water was let in the field when the planting was going on, and my coolies planted the shoots too deep; both were the results of want of experience in the new system. These and the filling up of the beds with water no sooner the first ploughing was done, had their effect on the plants.

The putting forth of the shoots was not quite regular which I attribute to the deep planting, but the growth which was luxuriant and the number of shoots put forth were ultimately such, that they exceeded the best anticipations of the most experienced cultivator. The average bush consisted of fifteen shoots, and the plants all round were vigorous. I exhibited two of the bushes at the Agricultural Show with the approval of the Assistant Government Agent.

Weeding and cropping of the tops of the leaves are two of the necessary operations which this system of growing paddy requires, but I was unfortunately not able to see them attended to.

Reaping and threshing out the grains were of course done in the ordinary way.

The following is an account of the expenses incurred and the yield obtained:—

PLOUGHING WITH THE NEW PLOUGH.		R	c.
Hire for one pair buffaloes for $\frac{1}{2}$ a day ...		00	40
do do extra do ...		00	40
Hire for one driver ...		00	37 $\frac{1}{2}$
do additional boy ...		00	12
PLOUGHING WITH THE NATIVE PLOUGH.			
Hire for 2 pair neat cattle ...		00	50
Hire for two driver ...		00	75
Hire for mudding by buffaloes ...		00	50
Repairing the dams ...		00	37 $\frac{1}{2}$
Levelling the beds 2 men ...		00	50
Manure cow-dung, a sprinkling ...		00	37 $\frac{1}{2}$
Cost of fence (portion allotted for the ext.)		00	30
Rooting out and transplanting 12 women			
and 2 men ...		£	00
Reaping and stacking 6 men ..		1	50
Threshing and winnowing 12 men ...		3	00
Nursery.			
Filling the nursery ..		00	12 $\frac{1}{2}$
Fencing two kurnies extent ..		00	82
Value of seed paddy, two kurnies		00	30
Second tilling, sowing, &c. ..		00	25

Yield.		R12	59
48 bushels and 3 seers.—Value at R1.25			
per bushel		60	15
Straw		00	37 $\frac{1}{2}$
Sale of fence sticks.. ..		00	12 $\frac{1}{2}$

R60 65
The adjoining portion of this land 26 kurnies in sowing extent cultivated in the ordinary way cost, when the labour is computed, R11.71 and yielded 27 bushels in corn and 70 cents worth of straw and fence sticks.

Considering the nature of the land selected the result obtained is very satisfactory; with the gaining of experience in the system, and the cultivation of larger extents the cost might be very much reduced. There are fields in this district which give this yield and in some more in the ordinary native way of cultivation, using of course a larger quantity of seed paddy, and if they can all be made to produce increased crops in proportion to their richness of soil by the new system, they yield and the saving in seed paddy will be enormous.

The superiority in weight and in fulness are two of the peculiarities which the paddy raised by the planting out system possesses over that obtained in the ordinary way. The former quality, I believe, is considered peculiar to grains containing more nutritious matter, and is a result of superior cultivation.

—I have the honor to be, sir, your obedient servant,

(Signed) J. P. GOONETILLEKE, President.

COFFEE IN INDIA: ASSESSMENT ON ESTATES.

To a request of the Wynaad Planters' Association that the Government would afford some relief in the matter of assessment on cinchona estates, in the circumstances of the great depression prevailing in the bark market, the Government are said to have replied, that the assessment on the land represents so insignificant a portion of the outlay on such property, that no appreciable relief would be afforded by any relinquishment of revenue. The rejoinder exhibits so grave a misapprehension of the nature of the Government assessment on land, that we deem it necessary to call attention to the subject, although it has frequently been most ably and exhaustively treated by our contemporaries, especially by the *Indian Agriculturist*. As however the great majority of our planting readers are coffee rather than cinchona planters, and as the same principles underlie the cultivation of both products, and, moreover, as a shrewd and successful native planter on the Nilgiris has furnished us with certain statistics and his experiences and views on the subject, we propose, on the present occasion, to discuss the Government assessment on land in its relation to coffee. The native gentleman to whom we are indebted for the materials for this article is of sufficiently advanced intelligence to understand the benefits derived from high cultivation and at the same time is quite conservative enough to follow the rigid economies of his own countrymen.

The cultivation of Coffee on the Nilgiris proper, at the present time he estimates roughly at 10,000 acres, mostly held under titles from natives—on which at the recent Settlement, a uniform rate of 2 rupees an acre was imposed, a rate not professing to be fixed on any recognised classification, nor on the half net produce principle adopted in revenue Settlements elsewhere. The extent under cultivation he apporitions thus, 500 acres in the Kundas, 1500 in Tooniad, 3000 in Mekanad and 5000 in Parugganad.

From extensive personal experience, and as the result of minute enquiries among coffee planters throughout the District, our informant reckons the average yield of coffee on the Nilgiris to have been, one year taken with another, 2 cwt. per acre, and the value 30 rupees per cwt. He believes that the accuracy of this estimate is borne out by the export returns of the presidency. The expenses of cultivation per acre are thus detailed:—

6 Weedings in the year at 3 Rupees	...	R.
Manning	...	18
Fencing	...	20
Handling	...	6
Distring and Reading	...	2
Picking	...	5
Preparing for Market	...	1
Supervision	...	1
Repairs to Lines, &c	...	1
Tools	...	1
Total	...	66

If the above figures are all reliable, we have absolutely an excess of expenditure over receipts, and no margin for interest on capital, profits and the Government assessment. The exchange, it is believed, covers the cost of shipping, curing, and similar charges and at the favourable rates now prevailing, maintains the industry from collapse. For a series of years, planters have had to contend with adverse influences including drought, leaf disease and bug, a falling market, over production in other parts of the world, where the land bears no burdens or insignificant ones. These influences have been and are still in active operation, and that they have been exact as may be inferred from the abandonment in whole or in part of estates scattered over the Nilgiris.

Moreover, it cannot fairly be urged that the planting returns are in the hands of speculators. It has long passed the mind of a European settler, and is now engaged in by men of tried and long practical experience who devote much time and labor to their

work, and spend their money economically and intelligently, with results however uniformly and continuously unsatisfactory.

No further economies can be effected in the expenses of upkeep, without prejudicing the safety of the capital outlay and resulting deterioration of the estates. Judged by the true principles which regulate the question of assessing land to revenue, the rate of two rupees per acre is far from insignificant, and if expenditure cannot be further reduced, it is obvious that interest on capital and Government assessment cannot be paid out of profit which is the legitimate source whence such charges should be obtained. Moreover, many coffee estates are heavily encumbered, and it may be added are absolutely unsaleable at the present time, as the result of a succession of bad seasons, low prices, insect and fungoid diseases. Interest is therefore an item which cannot be ignored. By the late Settlement, the planters suddenly found their burdens considerably increased. These burdens by falling upon the unproductive waste in every holding, enhance the price of manure, which in consequence is applied to the land in quantities far from adequate to maintain its productiveness.

We trust we have fairly represented the views of our native friend, and that these views will be acceptable to his European confrères, if not as absolutely correct, at least as approximately representing the truth, and establishing with some show of reason that the assessment is not such an insignificant factor in the question under discussion.

We are aware that several planters, who feel the hardship of the times, have been deterred from uniting in a memorial to Government knowing that the authorities have long entertained the views embodied in the reply to the Wynaad Planters' Association, but it is possible that a more intimate acquaintance with the planters, their industry and their grievances may lead Government to consider in what way, apart from the remission of assessment, really efficient relief can be afforded. The planters themselves, however, must formulate their own request and establish conclusively that the relief asked will be a substantial benefit. Government naturally believe that if coffee planting is *in extremis*, the relinquishment of a couple of rupees an acre is not likely to save it, and it must be confessed that this view has much in its favour.—*South of India Observer*.

COCONUT OIL PROSPECTS.

There has been a belief for years that the price of tallow governs the market for coconut oils, but importers and dealers have about come to the conclusion that the prices bear no relation to each other, and there appears to be abundant evidence to that effect. On occasions when the tallow market is low and depressed, buyers of soapstocks are disposed to refer to the fact as an argument against ruling quotations for other articles in their line, and are not willing to accept the other side of the situation when the market is against them. The actual barometer of values is the position of stocks, irrespective of all other raw soap materials, and it makes no difference whether tallow is elevated in price or otherwise, coconut oil will command a figure according to the demand and supply. London quotations rule the primary market, and the views entertained there regulate values in the United States, while the whole system is based on the visible supply and probable demand. The latter is well determined, as the consumption has steadily increased for several years, and operates as the most important standard to regulate prices, and to some extent to control the prospective price of the coconut oil market.

The prospect of a heavy crop of oil is predicted for a hundred tons, but it is claimed that part of this is held in warehouses, and that more than half of the amount will pass to the market. The consequence will be a heavy supply, and a consequent depression of prices, notwithstanding the increased quantity of the raw material. The small available stocks

owing to the non-arrival of the "Tweed," which has been condemned at Port Elizabeth in the Cape of Good Hope; its cargo of 500 tons will have to be transferred to another vessel, and some time may elapse before it can be received here, or it may be sent to London by the underwriters. The first lot of oil comes on the "Lucy A. Nickels," due on September 15th with 650 tons. One month later the "Sultan" is expected with 650 tons, followed by the "Edwin Reed" late in November with 720 tons, making the total visible supply for the balance of this year 2,820 tons, including the spot stock. The estimated consumption of Ceylon coconut oil in the United States is about 400 tons per month, and if all the stock afloat comes to hand, there will be sufficient to last seven months. It is claimed however that a large portion of the stock afloat has already been sold to consumers, and that the actual supply in first hands is smaller than the estimate given above. Spot prices can be well maintained until additional arrivals.

Cochin oil has lost money for several members of the trade who bought at seven cents or over per pound and are now selling at a small fraction above six cents. There has been a decline of three cents per pound since January last year owing to liberal stocks, and shipments can now be had under six cents. The loss of the vessel "Soteria" last May with 210 tons prevented a further decline, and no one has been heard to express regrets over the occurrence except consumers and insurance men. The condemned "Tweed" has also 100 tons, the arrival of which is very uncertain, while the "Suffolk" with 150 tons is now due, but the bulk of the latter has changed hands for consumption. These are the only arrivals until next March or possibly May, but the visible supply to that time including stock on the spot is placed at 550 tons, and as the annual consumption is estimated at about 800 tons, there will be barely sufficient to go around unless there are importations by steamer from London. The present dull situation is attributed to the large holdings of consumers, and not to the substitution of other soap stocks.

Domestic coconut oil is produced in such limited quantities, that its sale at a lower price than the imported has no effect upon the market. English oil and the San Francisco product are not heard from during the reign of high values, while the Cuban grade has passed almost entirely out of sight.—*Oil, Paint and Drug Reporter.*

THE JUNGLE OF BRITISH NORTH BORNEO.

(Viewed Medically.)

[The following article on jungle fevers in British Borneo, and various forms of disease known to the natives under the general term of "beri-beri," is interesting, and the views expressed are generally sound. We suspect, however, that sufficient importance is not attached to the atmosphere as well as to the drinking water. Fevers depend greatly on extremes of heat in the daytime and cold at night, the latter resulting in chill. It seems a sanguine view to expect a malarious locality to become healthy in six months. The Ceylon planting districts are generally healthy, but there are districts, such as Dumbara and Kurunegala, where "malaria" is chronically present.—*Ed.*]

The growing popularity of the jungle of British North Borneo, as a means whereby the important cultivation of Tobacco, Coffee, Pepper, etc., may be effected with profit, reminds us at this juncture that a few remarks on diseases incident in clearing may not be quite out of place.

Hitherto, the opening of the jungle has been attended with the appearance of certain specific diseases, which in order of frequency and occurrence are fevers, dysentery, and beri-beri. Of those

attacked, imported labourers are more liable than natives in the proportion of twenty to one; and of imported labourers Chinese are more liable than Javanese or Malays from the Straits in the proportion of two to one. Bangerese appear to have greater immunity than Javanese; while Boyanese, from their very frugal style of living, have less.

The term specific is used regarding these diseases in the sense that they are looked upon as produced by a special cause or causes, which have their origin in the soil, and from that source become infectious by inhalation or through the medium of drinking water. Their nature is bacterial, their distribution fairly general; but their effects are markedly influenced by locality. In cases for example near Suan Lamba, where the land selected has been marshy, subject to periodical inundation, and covered with virgin forest, the diseases have been more general, and the type more virulent than for example in Marudu Bay where the land has been capable of easy drainage, porous in its nature and covered with a younger jungle. However, whatever may have been the extent and type of the disease on the onset, a short time—from three to six months—suffices to work a change and to convert the previously unhealthy locality into one where life can be spent with comparative freedom from climatic disease.

Although the cause is thus specific, yet there are certain factors which combine to so lower the resisting power of the individual as to predispose him to an attack. Among these, exposure to cold and wet, mental depression, a prolonged low and inefficient dietary may be noted. The first shelter of the labourer is exceedingly primitive; consisting as it does of a temporary shed rapidly put together and affording little protection from wind and rain. Added to this, there are scanty clothing and a low temperature; the daily minimum temperature of virgin jungle varying from 65° to 70° approximately.

Secondly, imported labourers arrive on the estate heavily burdened with advances; and as the prospect of clearing these off does not, at first sight, appear hopeful, they naturally lose heart and abscond into the jungle in hope of escape; a course which in many parts of the territory has been fraught with disaster to the coolie. This condition of low spiritedness has frequently been observed and has been contrasted with cases, where coolies have arrived under similar conditions on estates in good working order where prospects were far more hopeful. Run-away coolies, who have spent a few nights in the jungle, and who have been caught or have returned of their own accord, are particularly liable to be attacked; and, as a rule, their case is unfavourable from the first. Lastly, the absence of an efficient dietary, as regards quantity, quality and variety of food stuffs appears in course of time to establish a form of cachexia differing little from pernicious anæmia. This result has been observed in two estates, remote from each other; but its onset is gradual and later in the history of the estate.

The duration of disease, with exception of the last form, is tolerably constant. By the sixth month it is, speaking generally, dying out. At the onset, the type is severer and the tendency to spread more marked than at any other time.

Taking the diseases seriatim, let us first consider the fevers. Of these the simple continued and malarious are met with. The latter are the more important, especially as they are at this period very apt to belong to the remittant class, and to be not uncommonly complicated with cerebral symptoms which render the particular case unfavourable. They appear during the first month; but should the soil be inundated, their appearance usually is delayed, till the drying of the soil commences. The poison in connection with these has been long known by the vague term 'malaria,' and the factors concerned in its production were also known to be a correlation of heat moisture and temperature. Only recently has it been discovered that the poison is bacterial in its nature, and finds in certain conditions of soil

a suitable nidus for propagation. Why the effects, should be more severe on clearing the jungle is explained by the direct action of the sun's heat in rapidly drying up the soil and thereby accelerating the growth of the germ.

Next in order comes dysentery, which appears slightly later than the former, and is usually associated with it, often coming on in its course. It is believed that whenever dysentery is prevalent in a malarious district, the contaminating medium is drinking water. The disease is amenable to treatment if taken early; whereas, if allowed to go unheeded, it is apt, if it does not prove fatal, to leave the patient a wreck as regards future usefulness to the estate.

Beri-beri in the paralytic form closely follows; and it is particularly apt to be a sequel of the two preceding, but it does occur independently. Cases, for the most part, are seen after the second month; but this is no rule, for the fully-developed disease is sometimes named dry beri-beri, which is not strictly correct; inasmuch as, although a few cases are found where dropsy is said to have never existed, the great majority have had dropsy more or less, preceding or co-existing with the other symptoms. The mortality is high, more especially among the early cases occurring in an epidemic, while the course is rapid; and death usually ensues from cardiac complications. Where the course is slower, and the patient is in a position of receiving good food and nursing, the fatality is very much less, but, as a rule, three or four or more months are required to effect a cure.

In British North Borneo this disease may be looked upon as essentially a jungle one; the infecting medium being the soil and water. The idea that a residence in a place of six to ten months is required in order to contract the disease, is erroneous; as in one locality five out of 30 coolies shewed symptoms after a residence of three months. It is far more prevalent in the East Coast than in the West, where, hitherto only a few isolated cases have been met with.

Another disease sometimes met with on our estates is what has been called anæmia or Wet Beri-beri.

The term beri-beri, by the way, is used by the laity to signify any case of dropsy. Nothing could be more misleading, for dropsy is a frequent symptom of tropical disease generally.

Anæmia is the prominent symptom and is very striking, as it gives rise to extreme pallor of the mucous membranes, for example the lips, tongue, etc. Its progress is steady; and its treatment very unsatisfactory. Intercurrent attacks of dropsy supervene, due to the hydræmic state of the blood. The labourer becomes a frequent inmate of the estate hospital for the treatment of this dropsy which soon disappears, he is discharged and goes back to work. In a short time it may be in less than a month—dropsy re-appears and he is re-admitted to hospital. This may go on for a considerable time, during which the strength gradually fails and death follows from exhaustion, very often preceded by convulsions and coma, or by an intractable diarrhoea or dysentery.

The disease occurs in those places where the dietary is found to be defective; more particularly in the insufficient daily quantity of protoids and a correspondingly large quantity of Carbo hydrates and fats. The staple diet from year to year having been rice and salt-fish with a little pork twice a month.

This form of anæmia has been looked upon as a form of pernicious anæmia; and it very much resembles in course, duration and symptoms what Dr. Kynsey P. C. S. O., Colombo, has called in the medical report of 1886, the anæmia and beri-beri of Ceylon, and what Dr. Lutz has described as achylostomiasis from its being associated as cause and effect with a nematode, achylostoma duodenale, found in small intestines. It appears therefore that this so-called beri-beri is essentially distinct from the other form and being so should not receive the name.

With reference to the management of these cases, the indications at the outset should be, as far as practicable, to avoid exposure to the virus (a) by the

choice of a suitable locality, (b) by strict attention to drink water; and to prevent action of predisposing causes (a) by a proper selection of labourers, (b) by providing efficient protection from exposure, etc. The locality should be slightly elevated; the soil should be porous, and capable of easy drainage; and, if an old clearing (Dusun) be near the same is preferable to living in a virgin jungle. Great care should be given to the water supply for drinking purposes. Superficial well-water is always suspicious in the jungle and should be avoided, or it should be boiled and filtered. River water may at times be good and usable, at other times, owing to its becoming contaminated with organic vegetable matter during heavy rains, it is impure and should also be boiled and filtered. The ordinary drip-stone is largely used here, and answers very well. In not a few instances has drinking water been traced to be cause of outbreaks of fever, dysentery and beri-beri. As the predisposing causes act by lowering the vital force of the individual, and thereby rendering him more liable to disease they should be removed. The coolies selected should be such as are less likely to fall sick. For instance, an attempt should be made to obtain the first labourers for felling and clearing from this country or from South Borneo, so that after the work has been so far advanced, the imported labourers may be brought on the estate, which by this time has lost a good deal of its former insalubrity. Again, substantial protection from exposure should be provided from the first. The floors should be raised from the ground some 5 to 7 feet and covered in all sides. The floors should be closed, especially where the coolies sleep. The night clothing should also be attended to, and any attempt on the part of the coolies at selling or disposing of their blankets and other articles of comfort should be put down.—*British North Borneo Herald.*

THE INDUSTRIES OF CEYLON.

(Summary of Paper read by GEORGE WALL, Esq., at the meeting of the Ceylon Branch of the Royal Asiatic Society, October 5, 1888.)

Mr. Wall dwelt first, in the spirit of modern political economy, on "the conditions necessary to industrial progress," and showed how first the despotic rule, of the native kings and then the conduct of the Portuguese and Dutch, had rendered the free interchange of products and the accumulation of wealth by the Sinhalese impossible. Hence there was no surplusage to export. As illustrations of the absorption or waste of wealth, he adduced the enormous cost of the great wall of China and of modern armaments. Knox was quoted to show that under the native rule it was dangerous for a man to have the reputation of being wealthy, as the King could claim everything. Mehemet Ali's policy in modern Egypt and the pyramids in ancient Egypt were referred to, as well as the ruins of Yucatan and the remains of Nineveh while the irrigation works of Ceylon were used as illustrations of the writer's proposition, that great natural resources might not mean surplusage of wealth well employed. The wealth of Egypt derived from the overflowing of the Nile was also effectively used, and the wonderful progress of Britain and North America under adverse conditions adverted to. The conditions were shown under which even religions and educational institutions might be perverted so as to hinder instead of helping progress. In Ceylon the very persons of the people and their labour were regarded as the property of the kings. Absence of capital and usurious interest exacted for seed advances were adduced as causes which hindered industrial progress. When the British took possession and up to the time when Sir Emerson Tennent wrote in 1846, there was no native capitalist in Ceylon. That want of capital as the cause of stagnation was shown by the wonderful

change which followed the introduction of capital in connection with the planting enterprise. In regions beyond the reach of capital and its influences stagnation still continues. Under the heading of "Inter-course and Market," Mr. Wall dwelt on the beneficial effect of free intercourse and interchange showing how steam navigation, railways, and telegraphs had brought the ends of the world together. Prohibitive and protective tariffs were denounced. The utter absence of roads at the beginning of this century and the difficulties of intercourse nearly half a century subsequently were dwelt on. The great benefits conferred by roads and railways were described, high railway rates deprecated, and the necessity of encouraging railway construction by private enterprise dwelt on. As connected with capital, free intercourse and markets, the importance of labour was urged and the necessity of sufficient rewards for labour being given,—adequate inducements for good work held out. In Ceylon, as elsewhere, the violation of this principle had led to disastrous results. The evil effects of caste were forcibly illustrated by the facts that supply and demand in different directions of employment were hindered by its operation, while certain pursuits, such as the preparation of coir, were tabooed. In its obligations and its restrictions caste was equally an evil, labouring for hire even, being considered a degradation. It was shown, however, that caste feeling was not entirely confined to the natives. Mr. Wall defended the natives from the charge of indolence, referring to Governor Sir Hercules Robinson as representing the class who prefer such a charge and Sir Henry Ward as conspicuous among those who more generously appreciate native character. The names of writers on both sides were adduced, and to our great surprise we found Mr. Wall dealing seriously with the insane rhapsodies of Charles Wynn Payne, who passed from prose to poetry in describing the natural resources of Ceylon, amongst which he enumerated gold and silver, copper and tin,

"Treasures not seen without but hid within."

Mr. Wynn Payne was never a permanent resident in Ceylon. He only, somehow, got amongst a body of natives who bestowed on him "a robe of honour," and from that hour he bored the Colonial Office and the public with wild writings. On the whole Mr. Wall's attitude towards the Sinhalese and that which he wishes others to adopt may be expressed in the ancient rhymed expression of charity:—

Be to their faults a little blind,
And to their virtues very kind.

The above gives but the barest idea of the wide scope of a long and very able paper, the intellectual eminence of which we appreciated without agreeing with all the propositions advanced.

DISCUSSION.

The CHAIRMAN:—I am sure we are all very much indebted to Mr. George Wall for the paper he has just read. I understand from the Secretary that the custom on these occasions is to invite discussion on the paper, and to address questions to the lecturer, which doubtless he will be happy to answer. A preceding chairman foreshadowed the time when a lady might occupy this chair. Perhaps I may therefore say now that even the ladies are not precluded from taking part in the discussion. (Applause.)

Mr. A. M. FERGUSON, c. m. c., said that as none of the ladies had responded to His Honour's invitation to take part in the discussion, he ventured to do so. He might be allowed to say that the meeting was an abnormally large one. He had no doubt that the anticipated pleasure of seeing His Honour for the first time in that chair had attracted a considerable portion of the audience,

especially the ladies—(applause)—but he was sure His Honour would agree with him that the anticipated interest of the paper from a gentleman of Mr. Wall's long experience and great ability must have drawn the larger number there. They had listened, he was sure, with very great pleasure to, and they had been very largely informed by a paper which had ranged over a very large portion of human knowledge, and over a very great number of the countries of the globe, from which illustrations had been drawn to enforce the leading doctrines of political economy which were now recognized by a considerable proportion of the Governments and nations of the earth. Mr. Wall had taken a very generous and a very magnanimous view of the character of the natives of this country. They all felt there was much to be said for a people who had been ground down by ages of despotism and oppression. On the other hand when they made the bare statement that a large proportion of the natives were indolent they were only stating the truth. Some man had laid down the axiom that every man living was as indolent as he possibly could be, and when they came to analyse the saying they found it was true. One man was indolent, because he did not like to work, and another man worked, because training and conscience compelled him to work, and they who had been born in a colder clime than that of Ceylon, had much to be thankful for, because the very inclemency of their climate had produced robustness, activity, and a desire for labour, and that labour had led to the accumulation of capital upon which Mr. Wall had so enlarged. As the hour was so late, he would only just touch upon one or two marked topics. Mr. Wall very properly alluded to bloated armaments as absorbing the capital of individuals and of nations. That was a true view, but they must not forget the other side of the question. If the Sinhalese were in a poor and distressed condition it was largely due to the fact that they failed in their duty to themselves in not organizing a permanent force sufficient to resist the invading Tamils who were the prime agents in bringing about the ruin on which Mr. Wall had dwelt, by destroying those magnificent irrigation works upon which the prosperity and the very life of the country depended, for as soon as the tanks and channels were destroyed, pestilence set in, famine succeeded pestilence, and a large population disappeared from off the face of the earth. So that a fair proportion of the revenue of any country spent in providing an army or a navy to defend the nation and its interests was simply a premium of insurance. Then, as regarded the operation of caste, Mr. Wall had shown how it had operated. With reference to the observation that caste exists in western communities, they must never forget the grand difference. Oriental caste means that a man cannot pass from a low position to a high one. In Britain matters were so different, that, as they all knew, the grandson of a weaver having married an Earl's daughter was virtually ruler of Britain for very many years—one of its most eminent men, Sir Robert Peel. If caste in Oriental countries would only admit of cases of that kind, they would have nothing to say against it. Mr. Wall had shown how it did operate. When there was a demand for labour in one direction they could not possibly get the supply to meet the demand, because only people of a certain caste would perform the labour. Mr. Wall had shown that a very large amount of work had been done by the Sinhalese people in furthering the industries of the land by taking contracts. They had felled jungle, they had taken contracts to build bungalows and stores, and a very considerable proportion of

them had been carters, and they had done good work in that way. But sitting there, and listening to that very able paper, he could not help saying mentally, "What has come over my old friend, George Wall? for, in treating of the industries of the island he said not one word about the class without whose labour British capital even would have been in vain, viz., the Tamil labourers." Admitting that the Sinhalese might have performed 10 per cent of the work which had been done in Ceylon in developing the resources of the country, he did not think he was beyond the mark when he said that they owed 90 per cent to the Tamil coolies. They had all been instructed, and he was sure His Honour would take a mental note of the statement, that if they did not progress with railways they would be left behind in the race by their competitors. He was sure His Honour would convey his feelings on that subject to His Excellency the Governor, and His Excellency would write to the Secretary of State, and so, as the Yankees say, they would "go ahead" with railway construction. As regarded railway rates he might say, even at the risk of being deemed a heretic, he was of opinion that if possible revenue should ultimately be obtained from railways. In this country they could not apply with over-strictness the doctrines of free trade. Direct taxation was very excellent in its way. It induced men to look at the mode in which their money was being spent, and where they had intelligent men it was all right; but in Oriental countries direct taxation meant that one rupee was collected for the Government and another rupee extorted for the benefit of the collector. So that he thought liberal rates obtained from railways were justifiable so long as the splendid system of roads which they had in Ceylon was kept up; it afforded a check, so that the railway department could not possibly exact higher rates than competition with carts would allow. If they charged rates that were too high, carts at once would come in and compel them to lower the rates. There were a great many other points worthy of notice in the very able and comprehensive paper they had listened to with so much pleasure, but the hour was late and there were other gentlemen—and ladies also, he hoped—who would respond to His Honour's invitation, and therefore with those remarks he could only say that he very highly appreciated the great ability of the paper which they had all listened to with pleasure. (Applause.)

Mr. C. KRISHA MENON (of the Agricultural Department, Madras) was the next speaker. He thought Mr. Wall had succeeded to a very great extent in proving that the imputation always cast upon the natives of Ceylon as indolent and apathetic had very little foundation when viewed in true economic lights. He went on to compare the natives of India generally with the people of colder climes, and said there were certain forces underlying the superstructure of every Society which explained the cause of the decline of industry. These forces he enlarged upon, and then went on to disagree with the lecturer in reference to his remarks about native rulers, entering into a defence of the last King of Kandy. Having referred to free trade and adduced instances in illustration of his contentions from the history of the Malabar Coast, Egypt, the United States and other quarters of the globe, he concluded with an apology for having left the country so late.

Mr. Ferguson said it was impossible to deny the fact that the natives of India had been hinted that, naturally, they would all like to do as little work as possible, and this was especially exemplified in the local proverb well-known to

them all:—"Better to walk than to run; to sit down than to walk, and best of all to go to sleep." (Laughter.) He had been that day reading a review of the wonderful work done by Sir Colin Moncrieff and his colleagues of late years for the Fellaheen of Egypt, and very much was true of the effect in Egypt which was true of the beneficial influence of the British Government in Ceylon. He would like just to refer to the response which the Sinhalese had made to the influence of good and enlightened Government, education, roads, the railways, &c. in directions outside those especially associated with their immemorial industries. For instance, a large number of them took a part in the coffee industry as owners of gardens and even large plantations; when coffee fell, they were eager many of them about cinchona, cacao and most of all tea. The teas sent to the market from Mr. De Soysa's plantations—all managed and the teas prepared by the Sinhalese—had got him quite a name. But it was in regard to the great coconut planting industry more especially that the natives had distinguished themselves by their marvellous extension of cultivation. Following European pioneers who forty years ago began in Negombo, Jaffna, and Batticaloa, the natives especially in the Western and North-Western provinces had changed the face of the land, until now their palm cultivation was nearly equal in importance to that of the whole of the other planting industries in the island. ("Hear, hear," and applause.)

Mr. A. M. FERGUSON, after a pause in the discussion, said he was very reluctant to appear again, but he had omitted to mention one of his most important mental notes, and he would like to take the liberty of just saying a few words on Mr. Wall's omission to notice that the British, with their western liberal ideas, went too far in 1830. They abolished compulsory labour,—the labour due to the state by the people, by the aid of which Sir Edward Barnes made that great road which laid the foundation of the prosperity of the country. But they abolished also the native customs in connection with the culture of rice, and in doing so, he believed, instead of forwarding the interests of the country they threw them back a quarter of a century. They had had to hark back in their legislation, and help the people to re-enact those rules by which compulsory service was exacted by the community from the community for its own good. The mistake of 1830 was one of their greatest, but it was one honourable to them, for it was made in the direction of liberality, but it showed how different were the conditions of a western community and those of people of different pursuits and different ideas, in oriental countries. (Applause.)

THE CHAIRMAN (Sir Noel Walker).—I do not propose to make any attempt to traverse the multitudinous subjects which have been touched upon by the lecturer, and by those who have spoken after him, nor do I wish to take you from the Emerald Isle to the United States and other quarters of the globe to which the native gentleman from Madras has introduced us. I have no doubt when we have an opportunity of studying his remarks, we shall see the practical application of them. There is a great advantage in seeing ourselves as others see us. There are two points in connection with tonight's paper and discussion which I should like to draw your attention, and to which I should like to refer. One is as to the industry of the people. I, for my own part, and I think many others have been very much irritated by those theory-mongers who go about the world and tell us that if we did but do that we might be a most industrious and prosperous people. The lecturer seemed to me— I did not exactly catch who he was—who pictured

the prospect of a surplus of 1½ million in Ceylon. What they were—rupees or pounds—I do not know. It has been my business for a long time to endeavour to make a surplus, and I should be very much pleased to catch hold of that gentleman and get him to put his theory into practice. I think his remark was in some way directed at the industry of the people. I object to making comparisons, but where they are in favour of the community amongst which we live I have less reluctance. I have spent 25 years in the West Indies. I inherited the traditions of a father who served the West Indian colonies for half-a-century. I have served from British Guiana in the South to the Bahamas in the North, and I say unhesitatingly that in the West Indies there is nowhere such an industrious people as that of Ceylon—whether it be Tamil, Moor, or Sinhalese. (Loud applause.) I should very much like my friends the tea planters of Ceylon to have a turn with the indentured emigrants of the West Indies, or the natives of the West Indies, or Africa. I speak as an official of 25 years' service in nearly all the colonies of the West Indies, with perhaps one exception, and I speak also from the other side. Fortunately or unfortunately I have been a sugar planter and proprietor, employing, jointly with others, some 400 or 500 Indians, the greater part of whom were indentured labourers. So that I speak feelingly and with some experience when I draw the comparison. Mr. Ferguson drew my attention very pointedly to railways. Perhaps about railways I may have a different notion personally to what I have officially. From some American associations which I have I personally, perhaps, would go a little ahead of my proper official position. I have great faith in the American doctrine which says:—"Put a railway down wherever you like: if there is population it is bound to pay." (Applause.) But that is the vexed question which is always brought forward—will it pay or not? A private individual often thinks differently to an official. For instance, if I had private funds to invest I might go into a country, travel through it, and learn a good deal about it, and I might be perfectly justified in investing my £20,000. But in that same country, looking at it from an official point of view, I should not be justified in throwing in the weight of my official position, unless I could by some calculation show that it would pay. That is the difficulty in which responsible officials are placed in considering projects of railway extension as compared with what I may call irresponsible or private persons. I hope, however, and I think that the public of Ceylon ought not to be altogether satisfied with the measure of railway extension which is before them at present. I think perhaps it may be sufficient for the day. When we are getting towards the end of that extension or getting partly through it, we may begin to talk about something more. There is one point at any rate in which I am sure the whole meeting will agree with me most thoroughly and unanimously, and that is in offering to Mr. Wall our cordial thanks for the trouble he has taken in preparing and in delivering this paper. (Applause.) I fear very much that he has read it at some personal inconvenience in regard to himself, though I know he had an offer of assistance, but he preferred to read it himself, and there is no doubt that a paper comes with more acceptance and more force from its author than second hand. (Applause.) I am sure I can in your names say to Mr. Wall we are very much obliged to him for his paper. (Applause.)

Mr. WALL:—Sir, and Ladies and Gentlemen,—I should indeed abuse the great kindness and patience which you have shown, if I were to unduly avail

myself of my privilege of reply: at the same time I think I should scarcely be justified in entirely abstaining. The paper was already too long, and I have therefore rather to thank the speakers generally for their additions to it rather than to answer them. However, I should feel myself very much at fault indeed, if I thought I had neglected to take due note of the vast influence that had been exerted over the industrial enterprise of this country by the British Government as a whole, and by the British planters in particular. But, considering the introductory nature of this paper, it did not appear to me—nor does it still appear—that there would be any appropriate allusion in particular to the Tamil labourer. The points I have had to establish were that the labourer must be remunerated, irrespective of his nationality, and, to endeavour to show what had been the causes of the low condition in which industry was when the British took possession, it was necessary, I thought, to make explanation which would sufficiently account for that low condition, and also justify, as far as it can be done, the attitude, the conduct, and the character of the people. But I think I have already alluded to the very great change that took place when British capital and British influence impressed themselves upon this country and its industries, and I dwelt on the very great benefit that had accrued, and expressed a hope that the range of that influence might be extended so as to embrace the parts of the country which had not hitherto enjoyed it. I was rather too brief, perhaps, in my anxiety to condense my paper, and I ought to have said in regard to modern armaments that they were necessary. I entirely concur with the view taken by the first speaker on that subject. Nevertheless, they certainly do involve a large unproductive expenditure. With regard to the particular armaments to which he referred, which impoverished the country, it was, like other things, the act of the governing power and not of the people. Therefore the people whose character and position I was anxious to exhibit were not concerned in that extravagant expenditure of money in meeting the incursions of their neighbors from the Malabar coast. With regard to the remarks about the railways, I must say that something far better than the rates of carriage upon roads ought to be offered to us by the railways if they are really to be of use to us, as they are in other countries. It would be vain for us to rely upon railways that do not economize the cost of carriage over roads. In other countries, the cost of carriage by railways is in some instances a third or even a fourth of the carriage by road, and I think therefore we have a right, especially as the industries of the country have paid for the railway, to expect that the railways shall be made subservient to the industry and progress of the country. If so, they must certainly do a great deal better for us than roads. That remark has reference to what the first speaker said—that we had always a check upon railways, that they could not exceed the cost of carriage upon the roads. But, in fact, the railway must keep under it to be of any service and go to a fraction of what the cost of ordinary rates would be. I am indebted to the last speaker—Mr. John Ferguson—for his mention of coconuts; but, in fact, that is one of those matters which comes more into the modern explanation of the industries, than to those principles of them to which my paper more particularly was directed. I think, sir, these are the only remarks which seem to me to be called for at the present, as the time is late; and I hope that, whatever omissions there have been in the paper, will be made good in the subsequent chapters, when I deal with the various industries specifically.

The CHAIRMAN said there was on the card a notice of another paper to be read—the antiquities of a place the name of which he would not endeavour to read, but he did not know whether at that late hour the meeting would like to hear the paper, have it taken as read, or postponed to another meeting.—After a pause he said he thought he might take it to be the wish of the meeting that its reading should be postponed till the next meeting. (Applause.)

He then proposed the adjournment of the meeting to the next customary day, of which notice would be given by the Secretary.

Mr. THOMAS BERWICK, before this resolution was put to the meeting, moved a vote of thanks to the Chairman and welcomed him on his first appearance at a meeting of the Royal Asiatic Society. He was sure they all hoped that they would often be favoured with the light of his countenance there. (Applause.)

The CHAIRMAN in reply said:—I thank you very much for the kind expressions which Mr. Berwick has used. It will always be a pleasure to me to be present, and I hope, in the language of Mr. Berwick, there will always be as much light reflected in the company as there is at present. Alluding to a remark that Mr. Ferguson made I cannot suppose that the presence of so many ladies has been attracted by myself so much as by the lecturer. (Applause.)

The meeting then terminated.

GEOLOGICAL KNOWLEDGE A DESIDERATUM FOR PLANTERS.

An article so headed in the *South of India Observer* generalizes correctly as follows:—

It is sometimes asked whether a theoretical knowledge of any science is of essential importance to those who have merely to attend to its practical applications? The sailor, it is said, may navigate his vessel without a scientific acquaintance with mathematics, or astronomy; the operative may manufacture chemical products without a knowledge of the laws of chemistry; and the miner may profitably extract from the earth's crust its minerals and metals, and yet be altogether ignorant of the deductions of geology. But while this is true—and it is true only in the sense of making these men the tools of the scientific skill of others—it will surely not be gainsaid that neither the sailor, the operative, nor the miner would discharge his duties less efficiently were he possessed of some knowledge of the principles upon which his own special art is founded. A man may proceed a certain length upon mere empirical skill, but empiricism is always restricted, has no progressive elasticity about it, and is utterly helpless when new conditions or unusual phenomena present themselves. It is science alone which can explain such appearances, and suggest the methods by which new difficulties may be surmounted. Scientific knowledge and the practical applications of that knowledge cannot be dissociated; the more exact and extensive the one the more certain and successful the other. What is often held up in foundation as "practical skill" is but the result of long observation and deduction, and the wiser that observation and the more exact that deduction, the surer and more successful that practical skill. The observation and deduction may not have shaped themselves into any system of science, but they are science nevertheless, and the offspring of much comparing, reasoning, and reflecting; and what it is more but the observation of phenomena, the marshalling of facts, and the drawing of legitimate conclusions? A man's practical skill is but the methodical arrangement of his experiences, and such an arrangement is science in the best and truest sense of the term. There can be no antago-

nism, therefore between science and art—between theoretical knowledge and its practical applications. Then follows the practical application:—

A knowledge of the composition and structure of the earth's crust becomes more and more indispensable; and hence an acquaintance with geology, if he would learn where this or that mineral is to be found, the abundance in which it occurs and the facilities with which it can be obtained for this purpose. The minerals and metals are not scattered broadcast throughout the earth. They have their places and these relations it is the function of geology to determine. Whoever, therefore, has to deal with the products of the earth in their economic or commercial aspects cannot fail to be benefited by some scintilla of geological knowledge. Let us endeavour to make this clearer by a few illustrative examples. And, first, the soils we cultivate depending for their fertility on their composition and texture may be naturally unfertile, and yet may be capable of improvement by simple admixture of other soils, by drainage, or by mineral manuring. The planter who knows the nature of his soils and sub-soils, their underlying rocks, is surely therefore, in a better position to correct their deficiencies by admixture, by draining, and by manuring than one who cannot discriminate the nature of these soils or detect their deficiencies. The elements of fertile admixture may lie within the same estate; the defects in composition may be corrected by the application of appropriate mineral manures; but how can the planter obtain this needed information save through a geological acquaintance with the nature of the materials he has to operate upon and apply? "Let him obtain it from the geologist," says some one, and apply it empirically. So far good; but infinitely better that the planter knew something of the matter himself, and could separate the wheat from the chaff of his scientific advisers. Secondly, as the worth of an estate depends not only on its agricultural but also on its mineral value especially in these days of gold mining, the planter who is unable to determine the character of its soils and subsoils, and is ignorant of its mineral structure, can never do justice to himself or his employer. A knowledge of the geological structure of an estate is not less necessary to fixing its real value, than a knowledge of its agricultural value; and it is from a lack of these that estates are either sold under their value or bought at unremunerative prices. No planter is worthy of the name who is incapable of appreciating this two-fold aspect of the value of landed property. Some of the older schools may affect indifference to science; but the younger members of the profession may lay it to heart that the knowledge which sufficed even twenty years ago will not sustain them in the race of life in these days of gigantic undertakings and more exact calculation.

The above are the main portion of a long article, the heading of which is scarcely comprehensive enough. The article really indicates what is true, that it would be a great advantage to every planter to possess a competent knowledge of agricultural chemistry, which includes at least the elements of geology and mineralogy, and also the properties and effect on soils of manures, artificial as well as natural. With the deeper mysteries of geology and mineralogy, an agriculturist need not be familiar, but with the constituents of the commoner rocks and soil and of all manurial substances he cannot be too familiar, so as to enable him to give practical effect to his theoretical knowledge.

TEA CULTIVATION IN INDIA. A PAPER BY DR. J. R. ROYLE.

Dr. J. R. Royle has contributed the following letter to *Nature*. The subject of tea cultivation in India is one to which numerous writers have devoted their attention, and not the least valuable portion of Dr. Royle's work, "The Trade of the British-India," is the bibliography of the subject with which, while recording his indebtedness

for much of his information to many of the English and German authors enumerated, he commences his remarks. In his preface he explains that in the course of an address on the products and exports of British India, recently delivered by him in Prague, he alluded to the fact that on the Continent of Europe tea was generally known only as either Russian or Chinese, and that it was barely known that India produced a large and annually increasing quantity of high-class teas, which are largely used in London for mixing with an improving China tea. The correspondence which ensued when these remarks were reported by the local press, induced him to publish the present work as the result of information he had the opportunity of collecting, while serving in India for eight years as paleontologist to the Geological Survey.

It is Dr. Feistmantel's aim to place before the German-speaking peoples of the Continent as complete an exposition of the conditions of the tea industry in India, as has already been laid before English-speaking people by other writers; and he therefore begins with an abstract of the early history of the tea-plant in India, the date of its first discovery as an indigenous shrub, and its first introduction into the different districts in which it is now cultivated. He mentions the first export from India to England in 1838 of twelve chests of tea, which sold for 19s. 6d per pound.

He points out the difference between the indigenous, the "China," and the hybrid varieties of the plant which are cultivated in India, and enumerates the various pseudo-tree which are known either in the frontier countries of India or in other countries; such as *Osyris nepalensis* or *arborea*, in Kumaon-Garhwal, and lately in Kashmir; *Elaeodendron pericum* in Burma, from which, when mixed with oil, salt, garlic, and assafetida is prepared the nauseous compound, to European taste, known as "pickled tea," *Ilex paraguayensis*, the Paraguay tea, or "Mate," of South America; *Ledum palustre*, or Labrador tea; the Tasmanian tea, made from various varieties of *Melaleuca* and *Leptospermum*; and the Faham tea, *Augreum fragrans* of Mauritius; and others.

The number of the plantations in the various provinces, area under cultivation, and annual yield of tea for all India, are given in detail; and the difference between the various kinds of China and Indian tea, as proved by analysis, are very fully treated of. The principal black teas made in India are flowery pekoe, orange pekoe, souchong, pekoe souchong, congou, and bohea; as also the several varieties of broken leaf, such as broken pekoe, pekoe dust, &c. All these are not, as is commonly supposed, the produce of different plants, but are prepared from one and the same plant, the classification being caused by the difference of age and development of the leaves used for the several varieties. The principal kinds of green tea are gunpowder, hyson, and young hyson, and these are manufactured almost exclusively in the North-West Provinces and Kangra.

It may be accepted as a fact that Indian tea is very rarely adulterated, being packed on the plantation, and shipped direct from the planter to the market; but "China tea" passes through many hands before it is packed for shipment, and is frequently mixed with willow or other leaves, or with artificial colouring-matter. But the adulterated tea is not now readily saleable in London, and is therefore re-exported to the Continent. A direct importation of tea from India to the Continent would insure the purity of the supply.

In a lecture given before the Society of Arts, in May last, by Mr. J. Berry White, and quoted by Dr. Feistmantel, a table is given showing the steady rise of the Indian tea crop from 232,000 pounds in 1852 to 76,586,000 pounds in 1886; and Mr. White estimated that the crop for 1887 would not fall far short of 90,000,000 pounds. The amount of tea exported from India between October 1, 1885 and September 30, 1886, is officially returned as 68,784,249 pounds, of which 66,644,749 pounds went to England. Nearly the whole of this tea is consumed in Great Britain, a small quantity being sent to the Continent mixed

with inferior China teas, and consequently sold as China tea. The percentage of Indian tea used in England has also been steadily rising, for whereas in 1865, China tea formed 97 per cent of the entire consumption, in the first quarter of 1887 the proportion was 51 per cent of Indian to 49 per cent of China tea.

Notwithstanding the steadily increasing production in India, China tea is still imported into the country; in 1885-86 about four million pounds were imported, but mainly into Bombay, where none is grown, and much of it for re-export to the Persian Gulf, Afghanistan, and some to Trieste, where it arrives as Indian tea.

Statistics concerning the consumption of tea show that the greatest tea-drinkers are the Australians, who in 1881 consumed 81 ounces per head of the population. England ranked next with 73 ounces, while the United States of America came next with 21 ounces. Russia, Belgium, Holland, and Denmark rank highest among Continental nations as tea-drinkers, but they only consume from 7 to 8 ounces per head of the population. Dr. Feistmantel fully indorses the prevalent English opinion as to the superiority of Indian to China tea, and attributes its being almost unknown on the Continent mainly to the fact that "China tea" is a much older, and therefore better known, product throughout Europe. Even in England, Indian tea took years to establish its reputation. It will in the end be as much appreciated on the Continent as it is in this country if a few merchants and tradesmen in different Continental cities, whose commercial standing will be a guarantee for the purity of the goods they supply, are induced to keep it. A special chapter is devoted to the cultivation of tea in Ceylon, and shows the marvellous progress made by this new industry in consequence of the coffee disease having caused the conversion of so many coffee plantations into tea plantations. In 1875 only 1080 acres were under tea, whereas in 1885 no less than 102,000 acres were occupied by it, and the exports rose from 82 pounds in 1875-76 to nearly four million pounds in 1884-85. The plantations are principally in the western and southern provinces of Ceylon.* Dr. Feistmantel's work concludes with an interesting chapter on caravan teas, compiled from an article by Herr Walter Japha, published in the *Revue Coloniale Internationale* for September-October 1887.

Some amongst us are apt to feel a certain amount of jealousy at the not infrequent employment of foreigners in Government appointments, and this feeling is perhaps intensified by the knowledge that in this matter, as in Free Trade, there is no apparent reciprocity—for we seldom hear of the employment of Englishmen by Continental Governments; but the present is an instance, and by no means a solitary one, of the great service done to us by foreigners who avail themselves of the information they have collected in the course of their employment by our Government to diffuse among their fellow countrymen such an intelligent knowledge of the productions of our distant possessions, as is calculated to largely benefit commerce or by leading to an extensive demand for the goods of which they write.

It would seem, however, scarcely just that the work of diffusing this knowledge should be left to other nations, seeing that the benefits are to be reaped by ourselves. It is hardly likely that in England it will be recognized, as it is in some other countries, to be part of the duties of any Government Department; but why should it not be part of the work of such a body as the London Chamber of Commerce, or the new Imperial Institute, to disseminate information regarding our Colonial and Indian products among Continental nations, and to translate and circulate any useful works on commercial and kindred subjects, published in foreign languages, among such classes of the community as they would be likely to interest?—*Indian Tea Gazette*.

* A curious mistake: the cultivation of tea in the Western and Southern Provinces is advancing, but the vast majority of the tea estates are in the Central Province, a large proportion in truth being converted coffee estates.—Ed.

COCONUT PLANTING IN THE WESTERN PROVINCE.

AN UNPRECEDENTED DROUGHT—RIGHT AND WRONG COCONUT CULTIVATION—CONDITION OF ROADS—THE PROPOSED AMENDMENT OF THE LABOR LAW—THE PRESENT NAWALAPITIYA REALLY KARAHANDUGALA—REMINISCENCES OF THE "DAYS OF OLD."

HAPPTIGAM KORALE, September 1888.

Three and-a-half months of dry weather in the south-west monsoon is unprecedented in the experience of the oldest inhabitant. We had a few light showers on the 26th and 27th, after which the sun shone and the wind blew in a way to lick up the scanty supply of moisture in a few hours. The wind is still steady in the south-west, and the battle of the monsoons has not yet opened. It is too soon to reckon up the bill of costs till we have had a good saturating downpour, but it is clear that it will be a heavy one.

The drought has been specially trying to last year's planting, a large percentage of which has already perished, and there are still many doubtful plants. The two and three year plants have a smaller number of green leaves than they had at the same date last year, and a crop of nuts for next year greatly under the average is already a settled affair.

Nothing is so detrimental to young coconut plants as rank grass, whatever the character of the soil or the changes of the weather may be. The practice of late years has been to plant in large holes, and if the field be gone over twice a year, filling in two or three inches of loose soil, and thoroughly weeding and keeping bare a circle six feet in diameter; the cost is very trifling, and the advantage to the plants most decided, as may be readily ascertained by comparing two fields of the same age where this work has been done on one and omitted on the other.

During the months of April and May last I turned over the soil one mamotte deep of a portion of a four year old field. The difference of the plants on the dug and undug parts of the same field is now unquestionable, and fully justifies the expenditure of Rs. 50 per acre that the work cost.

In planting up failures this year I put half a ballast basketful of cattle-shed manure into each hole. Where this was done there has been hardly any failure, and after all this drought the young plants are looking fresh and vigorous.

Our roads are, of course, in good order, and the D. K. C. are now replacing the wretched structures that have disgraced the Kotadeniya-Magunungumpala road since its opening, by first-class bridges.

I believe the planters will be generally content with the proposed amendment of the Labour Law communicated by Government to the P. A., and that the wisest thinkers represent any further tinkering, unless indeed the prepayment of wages for work to be done should be made legally binding on the coolie. That is to say, the coolie who made the first condition of his engagement a certain amount of prepayment, should be bound under a penal sanction to remain in the service till he earned his advance. The law gives the coolie a primary claim on the fee simple of his employer's property as security for his wages; to my simplicity, it seems only just, that the coolie should be legally bound to work his advances. The coolie's status by Supreme Court law is that of a day labourer, who can come and go at his pleasure, and for the debt he owes, his creditor is referred to his legal remedy, namely, a costly suit against a man whose only visible property is an earthen pot and a mat bag. The legal maxim that every wrong has a remedy hardly holds good in this case. The advance system has been forced on the planter against his will by pressure from the side of the coolie with only the coolie's good faith as security. The Tamil coolie has many good qualities, but pecuniary honesty is not in the list; he will agree to any terms, however hard, to get hold of money, and when he succeeds, all the resources of his mind are therewith employed in considering means of avoiding the fulfilment of his contract.

The proposal to make monthly settlements compulsory had better be omitted in the amendment of the law; the coolie's wages are already better secured than the planter's advances in having a solvent debtor in most cases; moreover, he has already the legal right to a monthly settlement, if it pleases him to enforce it; besides, no law can reach a debtor and creditor, who, for their mutual convenience, agree to defer a settlement. Such a clause would be a mere excrescence on the ordinance, remedying no old wrong and establishing no new right.

Your Nawalapitiya correspondent seems not to be aware that the present town is not the original Nawalapitiya, which is lower down the river. Karahandugala was the name of the land where the town stands, which continued to be the postmark for years after the office was established, but, the public persisting in addressing their letters to Nawalapitiya, the stamp was changed. Sandy Gray, a very remarkable specimen of the Aberdonian that some few of the old hands will still remember, was the first postmaster. My first visit to the spot took place on the 1st March 1841. The only inhabitant in those days was an old tavalankaran who had a hut on the ridge between the road and the river, situate at the junction of the paths leading into the valleys of three large branches of the Mahaweli. It very soon superseded Ambagamuwa as the capital of Uda Bulatgama, and it grew in importance up to the time when the Nannoya extension was opened; after which, some of the element of its prosperity must have failed. Among the hills and valleys of Uda Bulatgama and Kotmale, wellnigh one hundred Europeans lived and laboured forty years ago, and many a merry meeting they held in Junga Appu's hotel or Cathorn's store. Some half-dozen of them still survive in their native land, and only one of the early pioneers of the district awaits his call in Ceylon.

No. 2. (By another hand.)

FAILURE OF THE SOUTH-WEST MONSOON AND ITS RESULTS ON COCONUTS AND CINNAMON—NATURAL DECAY vs. BURNING—CHARACTERISTICS OF SOILS—VALUE OF COCONUT FIBRE AND SAWDUST.

SIVANES KORALE, Sept. 24th, 1888.

The time that elapses between the date of my communications and their publication very often renders ridiculous my remarks on the weather and its effect on agriculture. I shall therefore endeavour as far as possible to write on general rather than on local topics.

The south-west monsoon is on all sides admitted to have been a huge failure. The effect on agriculture generally of the paucity of rain is and will be disastrous. As far as the lowcountry is concerned, I think I may safely say that all planting operations have already proved to be a total failure. The loss consequent on the death of all the plants put out during a season is not to be gauged simply by the cost of the plants. There is the labour employed at the work, very often drawn away from a very important and urgent work which has to be postponed for another season, and what is of the highest importance the loss of an entire year before the planting work can be undertaken again, for mind you I am speaking of the lowcountry on the western coast where no prudent man will undertake planting during the N.-E. monsoon, with its 3 or 4 months of drought following the rains at the beginning of the year. Speaking for myself all the planting I did has proved a total failure.

Except on a few well-favored fields with abundance of water during all seasons of the year, the poor sowing will not yield a good crop, while as for the *maha* sowing, it is not a pitiful sight to see the young plants scorching in fields piping with fissures. The result of the drought on coconut crops all the country over both as regards number and weight will be marked. The cinnamon bush is perhaps the hardiest of all tropical products and will stand with equanimity, my own jovialness, neglect and ill-usage sufficient to kill outright any other product. When the effect of the drought we are passing through is seen on all sides in drooping

and scorched vegetation, to see the cinnamon bush decked in all the vari-coloured hues of a growing leaf bud—I beg pardon flush—is a very refreshing sight. But the drought has left its mark even on the hardy laurel, for the wood has refused to grow without moisture and we have a stunted growth of wood at present which will take a lot of growing before it is fit for the cattie during the next crop, which is due with the next monsoon rains. I very much fear, however, that the crop will be delayed this year as we have yet to get the July-August bud which did not make its appearance this year owing to want of rain.

Natural decay is but a slow form of combustion, and the ultimate results of both are the same. Some agriculturists argue from this that it will be better to burn vegetable matter and apply the ashes to the soil than to allow it to slowly decay and become gradually available as plant food. Before deciding the question one way or the other, it is essentially necessary to bear in mind that what is good for one class of soils will be unsuitable for another. There are soils with an excess of vegetable matter and there are others that have so little organic matter in them that they are extremely porous and allow to pass through them both moisture and manure. They have no retentiveness. To burn such soils or to burn vegetable substances before application to such soils, I think argues a want of knowledge of the leading principles of agricultural chemistry. Peaty soils, which are distinguished for an excess of vegetable matter, and are very often unproductive, are said to be greatly benefited and to be rendered fertile by being burnt. Another class of soils that is greatly improved both mechanically and chemically by burning is clay soils. The chief characteristic of these soils is their compactness. Their mechanical condition can be improved by draining as well as by burning. On some clay soils it is said that burning has the same effect as a heavy manuring. The opposite of a clay soil is a sandy soil which is extremely porous, is not retentive of moisture and from which heavy rain washes out its inherent elements of fertility as well as manure that has been applied to it. Adding clay to such soils to improve their texture is only practicable over very small areas. Another substance that might with advantage be used as a substitute for clay is vegetable matter. Decaying vegetable matter has one great advantage over clay. It has great absorptive properties in addition to retentiveness. The atmosphere contains ammonia, and ammonia is requisite for the growth of vegetation. Decaying vegetable matter or humus absorbs ammonia which the rain washes out of it to the soil to be taken up by the roots of trees. Besides these valuable properties of decaying vegetable matter, it in its decay gives out carbonic acid gas the source of carbon in vegetation, and carbon forms a large proportion of the woody substance of all vegetation. It will thus be seen that decaying vegetable matter plays a very important part in vegetable economy, besides being a necessary and very valuable addition to light hungry soils.

I have been induced to pen the above after having observed in my "walks abroad" the husks and branches of the coconut tree heaped and burned under the trees, on a well-known estate which has for its superintendent one of the best planters engaged in the cultivation of coconuts, and which cannot boast of a heavy soil. I am inclined to think that a little consideration will satisfy him, he is not doing the best thing for the valuable property under his charge. I know the slowness with which vegetable matter decays in sandy soils, but decomposition can be hastened by the addition of lime, and lime is easily available there. Anyone who has lighted fires on sandy soils will have observed how their character is still further altered for the worse after the process. They lose the little adhesiveness they originally possessed, and consequently all power of retaining water, and turn to a light, white sand on which even the lower forms of vegetation refuse to grow for a long while. To give body to a light soil, that is to make it retentive, it is necessary that all the available vegetable matter should be allowed to decay

on it. There is no form of vegetable matter so handy and that can be better and with less expenditure of labor incorporated thoroughly with a light soil than fibre dust and saw dust. The latter is available only to a limited extent. Not so the former. I have hopes that before long fibre dust will be reckoned at its true value.

DRUG TRADE REPORT.

London, September 13.

CINCHONA.—The quantity catalogued was nearly equal to that offered at the previous sale, the proportion actually disposed of at the auctions was very much larger. Even of the American barks only a quantity of cultivated Calisaya, in broken quills, and a parcel of 78 bales very old Petayo (1882 and 1883 import) remained unsold, an offer of 3d per lb. being solicited in vain for this bark. As regards quality, the assortment offered can only be pronounced moderate. The best lots shown were a few lots of Java root bark, and there were also some parcels of good strong yellow root bark from Ceylon, but no lot realised more than 1s 4d per lb. One catalogue contained 564 packages bark (mostly South America), offered "for account of whom it may concern," the concerned parties in this case being said to be the creditors of a firm of quinine dealers which recently came to grief. From the beginning an animated competition prevailed among buyers, and it was clear at the outset that the general expectation that the sale would "go off well" would not be disappointed. To all appearance, the best prices were realised at the beginning and towards the end of the auctions, though the bidding never flagged. It is generally admitted that a decided advance on the previous auctions rates was obtained, the estimates of the rise varying from 5 to 15 per cent., but we are inclined to place it at about 10 per cent., certainly not higher. The unit may thus be put at 2d to 2 3-16th d per lb. By far the largest quantity was bought by the representatives of the Brunswick Quinine Works, Jobst & Zimmer's agents, the representatives of the American manufacturers, and the Auerbach agents being also heavy buyers. The agents for the Mannheim factory appeared to have some difficulty in securing lots; they certainly bought very little. Messrs. Howards & Sons did not buy much, while Messrs. Whiffen did not compete at all. At the end of last week it was reported that the Mannheim quinine works had privately bought 600 bales Ceylon cinchona, averaging 1 1/2d per cent quinine sulphate, at the rate of 2 1/2d per unit per lb. The report was evidently spread for a purpose in connection with the impending auctions, as it is certainly not usual on the part of the quinine manufacturers to make such announcements out of a mere spirit of communicativeness. The "Britannia" has arrived from Valparaiso with 610 packages bark, but whether this is all Bolivian calisaya is not quite certain. Advices from Bolivia, however, would seem to indicate the probability of very heavy shipments from that quarter.

QUININE.—The market has been very strong and sensitive since our last report, and there is little doubt that considerable sales have been made at full prices, both by manufacturers, notably the Brunswick and Mannheim works, and by second-hand holders. Since our last report, the total of the transactions said to have been made amounts to considerably over 150,000 oz., but such figures should be received with caution, as they are entirely unsubstantiated, and one single transaction, especially in a sensitive market, is often multiplied several times. It cannot be denied that there is a good feeling for the article at present, and that it has repeatedly, after falling to between 1s 3d and 1s 4d per oz. rebounded, as it were, to the extent of several pence; but there certainly appears no warrant whatever beyond mere speculation for and considerable rise. We hear it said that up to the present the largest buyers are a firm of brokers intimately connected with the shellac trade, who evidently work on a preconceived plan of action. The sales reported since

last week are nearly all in "Brunswick" and "B. & S." bulk, partly spot, but mostly for October-December delivery, at 1s 5d, rising to 1s 5½d per oz., at which latter figure there are still plenty of sellers today, the German makers quoting 1s 6d per oz.—*Chemist and Druggist*, Sept. 15th.

CEYLON TEA IN AUSTRALIA.

The exports for the past four years have been as follows:—

	lb.	Percentage of crop.
1884-85	41,124	1.08
1885-86	151,757	2.12
1886-87	251,259	2.69
1887-88	479,626	2.31

showing that the Australian demand has increased elevenfold in four years, and the increase in the demand during that period has more than overtaken the increase in the supply. The particulars of the Colombo tea sales published in our issue of 27th ultimo shew that the market from which the Australian supplies are mainly drawn, is not being supported in proportion, a circumstance to be regretted. The ability of those members of the tea trade working in Colombo to supply markets other than that of London seems to us to be as important to the welfare of the planting interest, as is the support accorded to the "Ceylon Tea Fund." We are all hoping that the present Melbourne Exhibition will, among other things, lead to an increased demand for Ceylon teas; but how then if there be a complaint of an insufficiency of teas offered in the local market from which to choose for the Southern Colonies! Seeing that the chances are of quite as good a price being obtained from a local sale as from shipping to London—better indeed in the case of small breaks which are often disregarded in Mincing Lane—we trust planters will support the local market more freely during the present season.

THE TEA TRADE OF FOOCHOW.

REPORTS TO RESUSCITATE THE CHINA TEA TRADE.

We published last week, from the *Foochow Daily News*, a short article on the tea trade of that port at present, and since an agreement had been come to by the tea-men and the Kung-Yih Tong Guild. We were not in possession of the text of the latter document at the time, but having now received it we print it today. It is a very explicit document and it will certainly be carried out. In future years none of the black tea plantations are to manufacture or sell any tea after about the beginning of September. The usual three penalties, which the Guild knows well how to enforce, are fulminated against all who shall infringe its decrees, and we may reasonably expect that the new regulations will have the effect which the tea-men and the Guild and foreign merchants desire—a diminution of the quantity of low priced common teas. Thus we see that the Foochow dealers, probably the most sanguine body of men in the tea trade, the most speculative in business and eager to do a large trade—being sometimes not over careful as to the times on which they did trade, so long as it was made,—have at length seen the wisdom of listening to the advice of foreigners. This will cause bitter disappointment to the tea growers, but their interests and those of country middlemen and carriers and the *ch'ien* farmers alone will suffer. The Foochow native tea men have done a sensible thing but not better it has become inevitable, a fact which we hope will be brought to the notice of the Yamen as the trade at other ports is certain to be obliged to follow their example sooner or later. Our Foochow contemporary dealt, however, with the effect

which this measure of the men would have on the *lehin* and on the export duty, the deficiency on both promising to be very large and what is more to increase, unless a great deal be done to improve the make and quality of teas of all kinds. We have already written so fully on what should be done by the Chinese authorities that it would be useless to go over the same ground again. But we heartily commend the position of the tea trade at Foochow and the action of the tea men there to the consideration of those who have the means of bringing the state of the trade to the notice of the Tsung-li Yamen. We know that the report of Mr. Consul Aden, which we reproduced a few weeks ago, has been translated for the benefit of the Yamen and it would further enlighten that body if what has been done in Foochow were brought to its notice. There is good reason to believe that a few years of improved cultivation and manufacture would restore China black teas to the favour of the British public, and the green to the place they have so greatly lost in the American market. Simultaneously with this, new and more liberal fiscal arrangements in the country must be made. The neglect of these things will inevitably lead to the destruction of the trade, for India and Ceylon are increasing their production and are leaving no stone unturned to attract the buyers of the world to their wares. The increase in the export to Russia may possibly be regarded by the Tsung-li Yamen as showing that matters cannot be so bad as foreigners represent them. But the Yamen should also note that lately Indian teas have been well received in Russia, where in former years they could not find a market, and when Indian tea merchants get admission to a market, they not only hold their own but increase their trade in it, and this is nothing more than a fair reward for the care with which all who are engaged in Indian and Ceylon tea growing and preparation endeavour to supply teas of a quality which the markets, which they already ship to, require, and which are likely to attempt others they are invading. A similar policy must be adopted by the tea growers in China, and as time presses, it is to be hoped that the Tsung-li Yamen will be moved without delay to do something efficient.—*N. C. Herald*, Sept. 21st.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

On behalf of the planting community in Java steps have been taken to petition the Minister for the Colonies against any further extension of the Government cinchona cultivation in that island. The Minister will be urged to curtail official enterprise in that direction, until the plantations are brought to the footing of an experimental farm conducted on scientific principles. They were started at the outset with that object in view. Their extension as now pursued, leads to a harmful competition with private enterprise in that line of cultivation. The State moreover, by persisting in its present policy, runs the risk of losing heavily on a steady continuance of low prices in the cinchona market.

At Batavia, a factory has just been started to extract tannin out of the bark of trees, and forward it to Europe as export article. The bark used generally contains 10 per cent of the extract but sometimes higher percentages are met with. A sample once displayed at the Colonial Exhibition in Amsterdam held sixteen per cent. It consisted of dried and pulverised mangosteen husks. The success of the enterprise depends upon a cheap and easy way of extracting the tannin.

PLANTING IN DELL.

(Translated for the *Straits Times*.)

The new established tobacco growing companies now at work on recently opened districts on the East coast of Sumatra, do not seem to be run in a satisfactory fashion. The Deli Company points out that the three years in Europe manage these ventures ignorantly, to their own detriment in the near future. On the contrary of these new estates, managers have been appointed without security that economy and sound judgment will

be kept in view. Such lightheartedness cannot fail to work mischief ere long. Much of this kind of thing was pretty rife in Deli in the early years of planting, with the result that many pioneers burned their fingers badly before experience brought wisdom. The promoters of these new business concerns set little store by consulting experienced parties, and engaging old hands on the East coast of Sumatra. With the many Deli planter is suitable for manager without closer scrutiny into qualifications. On the other hand it must be noted that Deli old hands are not easy to engage, owing to the hard conditions they lay down before agreeing to join any of these new ventures.

FROM THE FAR SOUTH.

(By Old Colonist.)

SCARCITY OF FREIGHT—CEYLON TEA IN AUSTRALIA—MR. ELWOOD MAYS AND HIS NEW ENTERPRISE—AMERICA NOT A TEA-CONSUMING COUNTRY—AUSTRALIAN PREJUDICE AGAINST PACKET TEA.

TASMANIA, Sept. 18.

"No freight now for two months and no chance of any for some time to come, so if orders are not executed, know that we cannot get freight."

Such has been the burden of my agent's letters for the last two mails: what does it mean? Surely an appeal to the ever-courteous P. & O. agent would overcome this difficulty, or if not there's the German line, and now the Orient. It is particularly tantalizing at the present moment when duty has been lowered to 1d, to find no Ceylon tea in Melbourne; at a time too when the demand for "Ceylon" is really and rapidly increasing.

Although not laying myself out as a tea merchant, I have in a quiet way done my best to introduce and recommend Ceylon to the great tea-drinking bushmen, and watched for their verdict with keen interest—at first so invariably adverse, and yet after the second or third trial—how the lips smack with unmistakable approval! If the supply could only be kept up, there can be no question the Ceylon article would very soon supplant the China, but for weeks past I have daily been asked in vain, "Do you know where Ceylon tea can be had?" I have written to James Henty & Co. and two other houses, but the reply is "None in the market," and I am now come to accept and circulate Darjeeling in order to keep alive the taste for Indian teas. Absurd as it may seem, merchants talk of indenting on London, from whence there are no difficulties about freight. Relations with China are getting strained, and one would have hoped that Ceylon might have taken a legitimate advantage of this, but no, so engrossed are you in forcing your teas upon the unwilling Yankee, that your own sister colonies in the south are unheeded. (One would have thought that the experience of 100 years ago might have taught the Britisher that there was little profit by pushing tea in America!) It is all very well to talk profoundly of the importance of supplying 60,000,000 compared with only 4,000,000, but although I am not in all respects partial to the Australian bushman, in the matter of tea drinking I'll back him against any ten Yankees that ever spat in a circle. The requirements of Australasia are already, indeed, quite sufficient to wipe off the whole produce of Ceylon.

It may be said, however, that the prices hitherto realized in Melbourne have not been sufficiently encouraging, but it ought to be remembered that the market hitherto has been in the hands of the Elwood Mays of Melbourne, and these gentlemen with "stupendous" connections are not always the best fitted to push a special article, their long-established interests being apt to clash with the new enterprise. To one looking on quietly from a distance all the commotion over Elwood Mays seems truly ridiculous; no doubt he is "one of the most remarkable men in his country," so was

Mr. Scadder, but the idea of giving him 6,000 lb. of tea, while Melbourne cannot obtain for love nor money a single chest, is rather remarkable. Mr. Lavater and others have told me distinctly that though greatly preferring Ceylon tea they had the greatest difficulty in obtaining it. Of course, there is now Mr. Foulkes and his packets, but there is a well-grounded prejudice in the Australian mind against packet tea; nothing he likes better than a big chest in the corner of the room from which he can take a handful.

Had the impression made 8 years ago been followed up by regular supplies and a tithe of the trouble taken to cultivate the Australian trade which has been lavished on the non-tea-drinking Yankee, the market would have been in a very different state today.

THE JUTE TRADE OF INDIA.—Jute, as a fibre, is inferior to rhea or ramie, but then it is easily decorticated and cleaned. The result is that while in 1854-55 the exports from Bengal of this substance were valued at only 23 lakhs of rupees, those of 1887-8 reached the enormous value of 603 lakhs, the quantity being $9\frac{1}{2}$ millions of cwts. But this is not all: 3-7ths of the jute grown in Bengal is retained in Bengal for local consumption. The average yield is 11 cwt. per acre, clean fibre of course. These and other interesting details will be found in an article which we have marked from the "Pioneer" for extract into the *Tropical Agriculturist*. Next to cotton, we suppose, jute is the most important fibre produced in the world. Rhea fibre approaches silk in strength and beauty, while it can be mixed with wool. But in competing with jute there is the disadvantage of the difficulty and cost of getting rid of the ligneous matter.

TRADE AT HIOGO.—Consul Troup thus writes in his report to Mr. Trench on the trade of Hiogo and Osaka for the year 1887:—The export of tea last year amounted to 18,669,788 lb. as against 18,020,060 lb. in 1886; the declared value to \$2,882,568 (£456,406), as against \$2,649,072 (£411,512) in 1886. The average price per picul was \$19.90, a higher average than has been shown since 1884, the quantity of high-classed teas which was bought being somewhat larger than in 1886. Of the tea exported over 4,900,000 lb. were carried by steamers of the Canadian Pacific line to Vancouver, chiefly for transport to Eastern Canada and United States' cities. Over 6,700,000 lb. were carried by local steamers to Yokohama, and thence by Pacific steamers to San Francisco, chiefly for transport to United States' cities. About 1,200,000 lb. were carried via Yokohama, and thence by sailing vessels to different ports on the North American Pacific coast, and the nearest estimate at which I can arrive places the quantity carried by British steamers, via Suez Canal to New York for United States' Atlantic cities and Canada, at more than 5,700,000 lb.—*London and China Express*.

THE UNITED STATES AND CANADA.—The *Oil, Paint and Drug Reporter*, an American journal, shews, by means of figures, the enormous injury which would be inflicted on the United States as well as Canada by the 'retaliatory measures' proposed by President Cleveland for unworthy party purposes, just as the Senate disallowed the Fishery Treaty on equally unworthy and we may add wicked grounds. The article concludes thus:—"It will be seen from the above that a resort to such aggressive measures would not prove an injury to Canada alone, but would affect the United States in a manner that few would relish even for the sake of retaliation. Aggressive measures should only be resorted to after all other means of maintaining our rights have been resorted to and been found to be unavailing. Retaliation of the kind proposed, or indeed, of any description, is undignified and unworthy a great enlightened nation such as we claim the United States to be, but in any event it should be resorted to only after all other honorable means for settling the differences have been tried and failed."

We are not supreme in the art of ADULTERATION America is fairly good at the process, and there are other countries in Europe, notably Germany, who can give us points. A German chemical journal estimates that about 70,000,000 lb. of adulterated food is sold during the year, but how it arrives at these figures is not explained. Founding his facts on official reports, the writer goes on to say that the city analyst of Heilbronn examined 128 specimens of pepper, and found that 34 of them contained quantities of ground maize, flour, palm, kernel, and dried potato. A "surrogate" was in use for producing either white or black pepper. "Genuine Java coffee" was found to be 47 per cent burnt maize-corns. It was sold at the price of the best coffee. The maize and the coffee-bean are so unlike in their natural state that the former are "dressed, shaped, and glazed" by the trade to be mixed with the latter. The Poles are adepts at falsification. Out of 40 different specimens of tea examined by the police analysts in Warsaw 20 proved to be no tea at all. The analyst remarks that the use of the microscope is necessary in the examination of tea.—*H. & C. Mail.*

EDIBLE BIRDS' NESTS.—Mr. Steere, a traveller in the Philippine Archipelago, in the course of a paper, in the *American Naturalist*, descriptive of the central islands of the group, refers to certain caves in the island of Guimaras where edible birds' nests are found. The bird which builds these nests is a species of swallows or swift, and the caves are not found opening on the sea, but far inland where the cavities are covered by vegetation. Guided by an old Indian whose livelihood was obtained by gathering nests, and provided with a torch of native gum and another of the ribs of cocoa palm leaves, Mr. Steere started for the caves. After half an hour's rapid tramping through the steep, rocky valleys, he came to a low ledge of rock, 8 ft. or 10 ft. high, covered with vines and bushes, at the foot of which was a black hole, just large enough to crawl through, leading down into the earth. After lighting the torches the party crawled on hands and knees down a steep, rocky, narrow passage, the channel of a stream in the rainy season. It was simply a rift in the rocks, produced, perhaps, by an earthquake. Gradually all light except that from the torches disappeared, and when about 100 ft. below the ground and several hundred from the entrance, the weak, faint twittering of little birds as they flew about overhead was heard. When the Indian raised his torch, shallow hollows were seen in the roof of the cave, in which, partly supported by the sides, were the little cup-like nests. They were pure white in colour, made of little fibres interwoven with each other, and were still soft and damp. It was impossible for the birds ever to find out a place so dark from the light, with a dry face of rock and suitable depressions, or how they could build the nests in such utter darkness. A second cave, but not so far, was entered by a kind of well, and the curious, faint noise of the birds underground is described as "more like the sounds spirits might make than the notes of anything earthly." Near the mouths of the caves were rougher nests, built also of the same edible gum, and said to be those of birds who gave warning of danger to those within. The young frequently utter their cries to those of their parents, and the same nest is used year after year. In these caves the nests are collected and sold to the Chinese in Ho Ho. It should be noted that the caves here described by Mr. Steere are of quite a different character to the far-famed Guimaraon caves in British North Borneo, which are the principal source of the supply of edible birds' nests. These Guimaraon caves are quite open, and are as light as a cathedral aisle, so that the nest-gatherers have constructed ladders

and galleries of rattans to reach the nests in the roof. A curiosity of these caves also is that they are inhabited by myriads of swallows by night and of bats by day, the latter swarming out in clouds as the former swarm in, and *vice versa*.—*Weekly London Times.*

HARD AND SOFT PALM OIL

are thus noticed in an article in the *London Chamber of Commerce Journal*:—

The staples of trade in the Benue river are palm oil and palm kernels. From 1872 to 1881 trade was stopped in kernels. The stoppage was associated with the death of an old king of Benue, from which the people were led to believe that it they allowed the kernel trade, their "big men" would die. The main reason which influenced the situation was to keep down the rising generation, and to "ring" slavery and the trade advantages derived therefrom. The busy season is from April to July, the remaining months represent the slack season. A curious fact is, that on the Benue side of the river, that is, the right bank, soft oil is the staple; whilst on the left bank, and eastward, hard oil is obtained. Governor Moloney goes on to explain that the difference of manufacture is, that one—the hard oil—is the result of the cold process as regards manufacture, while soft oil is obtained by the boiling process. Palm oil is received in barter by the cask, each cask holding about two-thirds of a ton, or from 220 to 240 gallons, at the rate of 70 pieces "Madras" per ton, with 3 for "dash," styled "top cask," in all £7. 6s. a ton. Hard oil is not acceptable in the German markets; it has to be sold in England. The soft oil is said to be as good if not the same, as Lagos oil; yet it rarely commands the same price. Kernels are bought by cask measures of half a ton each, used for the purpose, for which 30 pieces of "Madras" are given, that is, 60 to a ton, or £6. Hamburg offers no present sale for Benue hard oil; nor will Benue soft oil, although said to be equal to that of Lagos, fetch as much on a Benue deal of Lagos. In consequence of buying kernels by measure, as is generally done in the Oil Rivers, there are no local grounds for complaint of soaking; and no cause for the cry after protective legislation, as is the case elsewhere. The Governor says he is supported at Benue also, in the opinion he has always held, that the remedy against soaking is in the hands of merchants and agents, who can apply, where such practice is resorted to, the system of buying by measure.

THE RICE TRADE OF SIAM.

Rice is now the great staple of Siam. It has been an article of export since 1838, when the treaty with Siam, then ratified, opened up the kingdom to the free trade. Prior to that, the kings of Siam never allowed a three years' supply of rice should remain in the country to foreign was allowed to be shipped abroad. When this law was abolished, a demand for rice sprung up, and the natives, learning that it was common to them, commenced planting for export, and young the acreage has steadily increased, thousands of Chinese engaging in the business. The demand for land has caused canals to be opened through sections which have lain fallow for centuries, and thousands of acres which were useless and infested with malaria now stretch out for miles with fields of grain, and a few of the old slaves are to be seen in the fields in a very undignified manner. The natives use the most primitive appliances in the cultivation of their fields, breaking up the ground with buffaloes and oxen attached to a wooden plough; but the soil is so fertile that the grain grows almost spontaneously. At times the water runs down the valleys for which a canal is drawn from the streams and rivers which cross the country in every direction. As the land is level, the water runs and falls with the tide; hence, the canals require no locks, and are

navigable for boats, which do all the carrying, since there are but few waggon roads, which are traversed with buffalo carts—huge, unwieldy two-wheeled vehicles.

The rice fields are laid off in lots of about one-third of an acre each—surrounded by an embankment of earth, from eighteen inches to two feet in height, for the purpose of holding water when the land is being prepared for planting or irrigation—for which the cultivator pays to the Government a tax of twenty-eight cents per field. To encourage the natives to open up new fields, no tax is levied on the land the first five years. When matured, the grain is cut with sickles and stacked similar to American wheat, and, when needed, is tramped out by buffaloes and oxen, six or eight animals being attached to a post, around which the straw is strewn, and over which the cattle tramp round and round until the grain is separated from the straw. Then the straw is piled up for the cattle and the grain is winnowed from the chaff and dirt in a machine a Chinese invention of a thousand years ago. The rice for export—Kow Moong and Kow Soon—is brought to the mills at Bangkok to be hulled, and then sacked for shipping. The natives hull their rice for home consumption in wooden mortars with wooden pestles; the latter they work with their feet, though many pound it out by hand. The first steam rice-mill at Bangkok was established by an American firm; but not finding it profitable, they disposed of their plant. Now the preparation of rice for market has grown into a prosperous business. The large crop this year and the increased demand has induced several firms to put electric lights into their mills, so that they can run night and day. There are now fifteen steam rice-mills in Bangkok, one in course of construction, and two at Patriew, a city thirty miles west of the capital. Most of the mills are in charge of foreign engineers. The only fuel used in these mills is the husk of the rice. Notwithstanding the country is full of rice—the last year's crop being an unusual one—the drought which has prevailed has dried up the water in the canals to such an extent that only a small portion has so far reached market, while thousands of piculs are spoiling in the boats which are stranded in the water-ways.—*British Trade Journal.*

THE VEGETABLE PRODUCTS COMMISSION.

The Royal Commission on Vegetable Products have issued the Fifth Progress Report, and continuation of the minutes of evidence, with appendices and a general index. The subjects dealt with and the information given are, perhaps, the most important to the farming community that have yet appeared. A deficiency of scientific and cultural knowledge, however, appears both in the examiner and some of the witnesses a good many irrelevant questions being asked, and answers are given which lose their value on account of a want of knowledge of the scientific names of plants, insects, diseases, &c., though, fortunately, most of those whose evidence is given in this report are experts in the subjects of which they treat.

The first portion of the evidence was taken at Wanganatta in September of last year, when information was obtained on tobacco, hops, roots, grapes, oranges and other fruits. In the next the very valuable evidence of Mr. J. L. Thompson of the Dookie Experimental Farm, was taken; Mr. Thompson handed in an essay on ensilage which must prove a boon to every farmer of sufficient enterprise to undertake the growth and manufacture of silage. The methods of cultivating and saving the silage, while perfectly effective, are plain and simple, and such as may be carried out at a small expenditure. Full details are given of the construction of the silo, the treatment of the fodder, the mode of packing, of testing the temperature and all other details, including the difference between sweet and sour ensilage.

Mr. Thompson remarks:—"It has been said that it makes no difference whether a silo costs £20 or £500; one will preserve ensilage as well as the other, the only requirement being continuous pressure. But you cannot make small silos as effective as large ones, nor

can you pack the fodder so well against rough surfaces as against walls that are smooth; consequently there is more waste of fodder with small pits and rough surfaces than with large pits and smooth walls. Cheap earthen silos (holes simply dug in the ground) are more likely to popularise the system of ensilage among the farming community than expensive masonry, and where the earth is sound this plan may be adopted with perfect success. I have seen as good ensilage made in this way as ever I saw from the most expensive silo, and small farmers need not hesitate to sink a hole in any good holding ground, put in their green fodder, and cover it up with two feet of earth—it will come out green and sweet six or nine months afterwards." This is valuable and timely advice and instruction for small farmers, and we hope to hear of many of them acting upon it, and commence preparations for growing some fodder crop, as we have so often recommended.

Regarding the two kinds of ensilage—sweet and sour—Mr. Thompson agrees with Mr. D. Wilson and other dairymen that sour ensilage is best for milch cows, and sweet ensilage for fattening stock. In speaking of stack ensilage Mr. Thompson says—"the only objection to stack ensilage is that our penetrating hot winds and sun have the effect of spoiling a considerable portion of the fodder around the edges of the stack, and the loss is so great that it will repay the farmer to construct a silo." He also gave evidence on dairying, farm crops for grain and fodder, olives, grapes, fruit drying, pigs, bees, &c.

Mr. John Zevenboom gave evidence on millet for broom making. There are two broom manufactories in the colony. He uses 15,000 lb. per month, and if the same quantity is used in the other manufactory the total amount will be upwards of 166 tons per year, which at 3d. per lb.—the present price—is worth £4,650. Mr. Zevenboom says—"Of course it can be grown in the colony," as our readers already know.

Mr. Francis Donovan and other tanners gave evidence on leather, wattle bark and other substances used for tanning. Wattle bark is really getting scarcer, and the price has gone up in 15 years from £3 15s. a ton to £9 or £10, so that there is inducement for landowners to undertake its cultivation. He says—"There has been no special foresight concerning the culture of wattle; persons have been allowed to go into the forest by paying a small licence fee, and the forests have been denuded without any regard to the wattle, and now it has got very scarce. There is no tannage that has been used so complete as that of the wattle bark, it is complete in itself. It is thought that among other substances used elsewhere, the sumach especially would thrive in the colony, and the demand for it is unlimited."

Dr. Carstairs and Mr. W. M. Ross gave their experience on the qualities and culture of sugar beet. Mr. James Matthews, Fyansford, spoke on street tree planting. He infers, from the townships and places he has visited, that municipal and shire authorities have little definite knowledge as to the best trees to grow for their streets. He considers the best deciduous trees for streets in the colony are elms, oaks, oriental planes and poplars, in which we entirely agree with him, as also in the impropriety of planting different kinds of trees, especially evergreen and deciduous, in the same street. Mr. Charles French, of the Botanic museum gave evidence on insects injurious to fruit trees and other farm and garden produce. Mr. G. W. Knight, senr. nurseryman, &c., Sandhurst, gave a large amount of very valuable evidence on grapes and other fruits, as well as on various other subjects. Also enlarged microscopic figures of the flower of the grape in different stages, and he handed in a descriptive list of grape vines planted in the experimental ground at the nurseries. So valuable was the evidence given by Mr. Knight considered, that the chairman of the commission and Mr. J. L. Dow, M. L. A., gave special thanks to him for giving the commission the valuable results of his patient research and many years' experience. Messrs. W. Waller and A. J. Cheke gave evidence regarding tea. Miss F. Campbell gave interesting evidence on fungi and fungoid diseases of

trees and other plants. Miss Campbell's view of the Government appointing an entomologist is that he should be a biologist, or rather vegetable pathologist. Mr. Robert Lucas went fully into the culture and management of hops.

Much valuable matter is contained in the appendices, including tables showing the quantities and values of articles imported into the colony during 1886 to 1887 which can be produced or manufactured in Victoria, affording a valuable study for all interested in agriculture or horticulture. Also the report of the Wattlebark Board of Inquiry, 1878. Papers by Mr. A. N. Pearson, chemist to the Agricultural department. In a paper by Mr. Cureton (Chaffey Bros.), on the Tillage and Products on Irrigated Land, may be found a quantity of information of great value to irrigators as well as other cultivators. Dairy Farming in Italy is from Mr. A. Dekin's Memorandum on Water Supply. Mr. George Neilson, curator of the garden of the Royal Horticultural Society, furnishes a short paper on the Registration of Seeding Fruits raised in Victoria. It is to be hoped that every farmer in Victoria will be put in possession of a copy of the report, to read and study during the long winter evenings.—*Leader*.

FOOCHOW TEA GUILD AGREEMENT.

The following is a translation of an agreement with regard to tea drawn up by the Kung Yih Tong Tea Guild, Foochow, and signed by all the hongmen of that place:—

In the case of any dreaded trouble or calamity, men are accustomed to take precautionary measures beforehand, and guard against the dreaded evil. This should be so in all circumstances. Especially necessary is it to take precautionary steps with reference to our tea trade. We must not adhere obstinately to old ways of doing business, but change our practices and adopt new modes of procedure.

Now in former years the amount of Autumn teas brought down here was much too large, and consequently the prices were exceedingly low, indeed so low, that words cannot be found to express it. This year however we hope by carefulness and forethought to mend matters and render them more profitable to ourselves. In order to do this let us, the heads of all the tea hongs, meet together in our public meeting-place and discuss together and agree as to what regulations should be adopted. In the first place, it is desirable that all teas of the 3rd picking whatever description should, from the 15th day of the 7th moon, be stopped (from coming to Foochow), but for 10 days however after this date, viz., to the 25th of the 7th moon, indulgence may be granted and tea may come down. In the 2nd place let all the tea hongs all over the country in every place, at once, and without delay, collect from the teamen (traders) the Lekin permits so that no tea shall pass the Lekin houses. But should the teamen refuse to surrender their Lekin permits and dare to bring down the tea (to Foochow) then the tea hongs (at Foochow) are not to receive the tea thus brought but to refuse it absolutely. Should any one be bold enough to break these regulations he shall be held as having transgressed the guild rules, and shall be punished accordingly. Fortunately the heads of all the tea hongs have agreed earnestly and zealously to see that these regulations are carried out, and so protect our interest and trade. 3rdly.—It is decided that after the 30th day of the 7th moon (each year) none of the black tea plantations shall manufacture or sell any tea, and any one doing so after the above date, shall be punished for having broken the regulations. 4thly.—With reference to the teas already in the tea-hongs, 10 days after the above date will be allowed for packing &c. &c. viz., to the 10th of the 8th moon, after which no packing &c. will be allowed. Should any one disregard these regulations, strict examination shall at once be made, and it shall be decided by the heads of the various tea-hongs what punishment shall be indicated on the transgressors. Should any of this tea require re-packing, the fact must first be clearly notified to the heads of the tea-hongs, before it is allowed. The two sorts of tea called *Hanchang* and *Pohlo*, do not come under any of these

restrictions or prohibitions. The teamen of the western and northern districts shall on the date above fixed, give up their Lekin permits to the heads of the various tea-hongs, but if these teamen themselves should secretly give money to the manager of the tea-hong for the purpose of paying the Lekin dues, and thus evading these regulations, enquiries shall be at once set on foot to discover which of the managers received such money and the head of the tea-hong to which he belong shall be muted in accordance with the regulation already fixed, or should the teamen secretly go to any other house of business and contrive to dispose of his tea to said house, and it comes to the knowledge of this guild, they will at once write a letter to the Foreign Chamber of Commerce and inform them of the circumstance and let them decide what is to be done in such a case. This guild because of the very weighty and important matter, of protecting our tea business, have taken these unavoidable measures, and now make it known to all concerned with the earnest hope that the head of each tea-hong, and the teamen will together and with one consent abide by this agreement and not break these regulations. This is of the utmost importance. Done at the Tea Guild Hall &c.

Referring to the above, the *Foochow Echo* says:— We publish today a literal translation of the Agreement drawn up by the Kung Yih Tong and signed by all the Hongmen in this place. It corresponds pretty closely with the ideas formed regarding it on hearsay, but there is one important particular in which it does not agree. We refer to the penalty clause. It was generally understood that a fine of a dollar a package would be imposed on any Hong or Tea-men violating its terms, and now we find that any discovered infringement is to be referred to the general Chamber of Commerce, for the purpose, we presume, of getting that body to award a punishment. Opinions will differ as to the rightness of this course. Some will no doubt think that such cases should be referred to a tribunal of their own countrymen. Next, we may notice the great indulgence that has been extended to the local packers, in giving them until the 10th of the 8th moon (15th Sept.) to complete their season, though the reasons for this are no doubt considered fair. And then we would draw attention to what was not, we think, previously understood, namely that these regulations do not apply to this year only, but to an indefinite number of future years.

We are impressed at first sight with the genuine tone of bona fides that runs through this document, and so long as the price of common tea in London remains at 3½ per lb., and nothing occurs to interrupt the steady increase of production in India and Ceylon, we believe that the agreement will be faithfully carried out. But such things do happen as unforeseen interruptions to steady production. Droughts sometimes occur in the East, and such things as strikes amongst labourers are not wholly unknown. We do not say that such catastrophes are likely: on the contrary they are improbable. Supposing, however, something were to occur to remove the gloom at present hanging over Foochow tea, how would the Chinese act in regard to this arrangement? We are not parties to it in any way. The terms of it have certainly been mentioned to buyers in a casual sort of way, but only for the purpose of endeavouring to give support to prices. As far as we can see, there is nothing to prevent their calling another meeting of the Kung Yih Tong and annulling the agreement off hand if they saw it to their advantage to do so. Such a course would not be altogether without precedent. They would be accountable to nobody. Far be it from us to throw doubt on their keeping good faith with themselves and with us in the present instance. We trust that the compact will be carried out in its integrity, and that it will benefit all interested in the trade.—*Canton China Mail*.

CINCHONA GROWING IN INDIA.—Home elements in their criticisms of Mr. B. S. P.'s paper are most unjust to the Indian Government. It went in for *Lad-riana*. But it won't grow everywhere, as I know to my cost.—*Cant.*

TEA PLANTERS AND TEA AGENTS.—The *Indian Planters' Gazette* says that a tea-planter has "played it down low on the wily and infallible Calcutta agents," and distinctly scored off them:—"I had" says the tea-planter, according to the paper mentioned, "samples sent me by my agent and was told to make similar teas as they were considered 'desirable teas.' On receipt of these samples I repacked them in lead, put my own garden mark on them, and sent them down as my own. The report I received was to the effect that 'these teas are most undesirable; your system of manufacture must be seriously wrong. We would advise higher withering and less fermentation.'"—*Pioneer*, Sept. 21st.

TOBACCO CURING EXPERIMENTS.—At the request of Mr. H. Caine, the tobacco expert, the Agricultural Department of the Board of Revenue has asked the Collector of Madura to instruct the Tahsildar of Dindigul to afford Mr. Caine every assistance in procuring on lease for a year about eight acres of land near Dindigul for the cultivation of tobacco to be experimented upon. A small shed is also to be erected near the land for curing the leaves. Of the indigenous tobacco submitted to Mr. Caine, the Havana and Vizagapatam samples grown at the Madura Farm were considered the best for the manufacture of cigars, and seeds of these two varieties are to be utilized in the experimental cultivations. The tobacco grown in the Kurnool district is cured for the native market, and Mr. Caine thinks it would not be advisable at present to interfere with the native taste, which requires heavy tobacco, coarse and strong; even should the cultivator be convinced that fine wrappers would pay him better, yet he would not find a market in his vicinity to dispose of the leaves.—*Madras Mail*, Sept. 26th.

JERUSALEM AS A TRADE CENTRE.—According to the report of the British Consul at Jerusalem on the trade of that town for the past year, it appears that exports, notably those to the United Kingdom, have increased, owing to a good harvest, while there is a small decrease in imports. Statistics are not obtainable, but it is estimated that two-thirds of the goods imported at Jaffa go to Jerusalem, which is the market for the villages of the interior and for the Bedouins. The chief industries are the manufacture of a coarse soap sent to Egypt, and of objects of devotion in mother-of-pearl and olive wood, in which considerable art is now displayed; £20,000 worth of these were exported in 1887 to Europe and America. The Jewish immigration has been checked by a regulation of the Porte prohibiting Jews from settling in Palestine, and restricting their residence in the country to a period of three months. The culture of the vine by German settlers is extending and the quality of the wine produced is improving. The price of land in the vicinity of the city has continued to rise in price, the best fetching, on an average, 6s the square yard, which not many years ago could have been obtained for a sixth of the price. This rise is due to the Jewish immigration before it was interfered with, to the multiplication of religious establishments and educational and charitable institutions, English, French, German, and Russian, and to the desire to live beyond the walls of an insalubrious and confined city. But the acquisition of land by foreigners is subject to two disadvantages, for all claims and questions concerning it are settled by the native courts, the Consul having no right to interfere, and the owner cannot build on it without the consent of the Government. German trade with Palestine is rapidly developing, on account of the large and prosperous German colonies which have established themselves in Palestine, and the members of which are invading all branches of commerce, industry, and handicraft. The colonists exercise a beneficial influence on the natives.—*Times Weekly Edition*.

ORANGE CULTURE IN AMERICA.—The question as to the cultivation of the Orange as a remunerative crop comes before us in a report on the fruit produce of Sicily, where it is stated that the cultivation of Oranges and Lemons in California, Louisiana and Florida has assumed such vast proportions that it is a matter of certainty that at no distant period the import of the former of these fruits into America, which is one of the chief customers for this article, and the carrying business, which gives so large employment to English merchant vessels, will wholly cease, and, although the exportation, owing to a failure in the crops in Florida through an unprecedented frost, was largely increased in 1887, yet it was carried on at such prices as not to be remunerative. In fact encouraged by the extraordinary prices which were obtained in the American markets for Sicilian produce some years ago, the Sicilian cultivators increased their Orange and Lemon plantations to such an extent that the over-production has increased to a ruinous degree. Indeed, the prices at which the fruit was sold in America in the past year did not, in some instances, even cover the freight. It must be added that their bad packing and the choice of inferior fruit which might have been used for the manufacture of essences and extracts at home, have not a little contributed to the depreciation of Sicilian fruit in foreign markets. The export of Lemons, however, may be continued on account of the special aptitude of the Sicilian climate for the growth of these fruits owing to the absence of frost.—*Gardeners' Chronicle*.

PROTECTION FOR FRUIT TREES.—Says Dr. Taylor in the *Australasian*:—

M. Magny, president of the Horticultural Society of Constance, writes to say that he has applied a solution of sulphate of copper to his fruit trees with great success, as regards protecting the young buds from birds which love to devour them. Not a bud nor a blossom was damaged by the application, and not only were the birds kept off them, but insects as well. The following is M. Magny's receipt in full:—4 lb. of lime slaked in six pints of water, 1 lb. of blue stone (sulphate of copper), dissolve in 67 pints of hot water, add then 1 lb. of soot, and clay enough to give the liquid a semi-fluid consistency.

There is a stupid omission to state what is to be done with the slaked lime! We suppose, but cannot be sure, that it is mixed with the liquid sulphate of copper.

BOUNTIES ASKED FOR COTTON-GROWING IN QUEENSLAND.—At Brisbane, on September 10, a deputation of East and West Moreton farmers asked the assistance of the Premier towards the growing and manufacturing of cotton in the colony. They pointed out that cotton had been successfully grown previously, and if farmers were encouraged to grow it by the establishment of local cotton mills, which would absorb the produce, their industry would bring into profitable use a large area of land now lying idle. They asked the Government to offer a bonus of £5,000 for the first 5,000 yards of cotton goods manufactured in the colony from cotton locally grown, and to grant 5,000 acres of land at the expiration of three years from the establishment of the first cotton factory. In reply Sir T. Mellraith expressed the opinion that the cotton manufacturing industry would be maintained in a flourishing state with the assistance of the ordinary protective duties. The Premier promised to carefully consider the question. "We need scarcely say that the encouragement of cotton-growing in suitable districts by the natives of Ceylon—now that a Ceylon manufactory is to be started—is an object deserving of the special encouragement of the local Government. The Assistant Agents ought to be empowered to offer money rewards—small bounties in fact—for an appreciable quantity of cotton grown from the best seed now available and which might well be distributed free of cost to the people.

RICE AS AN ARTICLE OF FOOD.

This country, says the *Times-Democrat*, is the largest producer and one of the smallest consumers of rice among civilized countries. A comparison with the consumption of this grain in Great Britain seems to show that its use is steadily extending in that country, and as steadily declining in the United States. Following are the figures of rice consumption per capita here and in Great Britain:

	1886.	1885.	1884.
Great Britain, pounds	10.76	7.43	9.76
United States, pounds	3.55	3.62	3.90

The relative estimation in which it is held in the two countries is aptly shown by the fact that in Great Britain it is used mainly as an article of food, while in the United States a large portion is used in making beer. That prices have but little effect upon the figures and, consumption is shown by the low price now ruling. The above paper also gives what it thinks to be the real reason of the light demand for rice in the United States. It is that in the greater portion of this country the art of cooking rice is absolutely unknown. This is more especially the case in the north and west. The consumption is greater in the south, where the mode of cooking it is understood. The commercial value of this cereal is well known. Louisiana is especially interested in rice culture, and an improved demand for rice as an article of food would help the rice-growing interest of that State. It is suggested that the public needs to be enlightened as to rice as an article of food in order that the demand for this home product may be increased.—*Planters' Monthly*.

EARTHEN FLOORS FOR STABLES.

I had always been accustomed to a solid earth floor for my horses until four years ago, when I removed to my present location. The situation of my stable is on a hillside, thus making the rear stalls 3 feet above the ground. The floor I found to be a good one, and the greater ease with which it could be kept clean reconciled me to the change, but it was not more than two months after occupying it that I noticed that the feet of my main work horses were getting dry and horny. They showed signs of cracking, and the blacksmith who shod them complained of the difference in the way they handled. I at once concluded to blame the stable floor with the trouble, and was considering the advisability of taking out and filling up with earth, when it occurred to me to try earth on top of the floor, and I did so. At the time we were making a new road, we struck a vein of very tough yellow clay. My stalls are 6 feet wide, and placing a 3-inch cross-piece 7 feet back from the manger I filled the intervening space with clay, ramming and hammering it very thoroughly, so that no lumps remained unbroken and no spaces were left to fill up and get foul with liquid matter. I rounded the clay up on top so that drainage from the middle of the stall would run to the rear. Now after three years of constant use, my work horses never run out, for I find it just as good as the solid earth floor. It is easily cleaned. The horses' feet regained their natural condition very soon. In dry time the horses do not wear their shoes off and disturb the neighbourhood stamping. When the surface gets to hard, a sprinkling of water makes it all right again. If it wears into holes or becomes foul, it is easy to scrape off and level the surface, and if necessary hammer in a little more clay. On the whole, it is by far the most satisfactory floor I have ever tried, and I shall not soon go back to the solid earth or the solid boards.—*Natural Stockman*.

FOREIGN COMPETITION ON COTTONSEED PRODUCTS.

There is a popular notion that cottonseed must be even more of a refuse in Egypt and the Indies than it ever was here, and it follows as a natural consequence, that the looked for extortions of the great monopoly will result in the development of

competition from the East and the eventual dwarfing of the domestic industry. To those who are influenced by facts rather than fancies, and who may be as uninformed as to the facts in this case as are those who conceive these new elements of danger, it may be well to give a few figures, showing the relative importance of the cotton production of America and the remainder of the world. The figures are for 1884, the latest date for which complete returns are available, and show where the world's supply of cotton was grown that year. They are as follows:

	Pounds.
British India	500,000,000
Egypt	230,000,000
Brazil	55,000,000
Asia Minor... ..	7,000,000
All other	15,000,000
Total outside the United States ...	807,000,000
The United States... ..	2,110,258,000
Grand total	2,917,258,000

Referring to these figures, the *American Exporter*, in an article directed mainly to the subject of competition between the American and foreign staple, says:—"This shows how completely the cotton manufacturing world must depend upon the United States for existence, and the futility of all attempts at developing a cotton field to compete with ours. We possess all the natural conditions necessary for the growth of the finest cotton, and as to appliances we are years ahead of the most advanced producers elsewhere."—*Oil, Paint and Drug Reporter*.

AN EXPERT DESCRIBES THE METHOD OF CHEAPENING SPICES.

"Rice flour and white meal can be mingled with white pepper in reasonable quantities and experts in spices cannot detect it," said a leading grocer to a reporter.

In fact there is no trade in which adulteration for pecuniary profit can be carried on more profitably and with less chance of detection than in spices. Terra alba, a fine marble dust, is exported from Italy to this country in considerable quantities to mingle with white pepper. Mustard mixes with sago flour, rice flour and a bit of aniline coloring without detriment to the appearance of the mustard. Treat the mixture with iodine and you expose the adulteration; but the average consumer of mustard is not apt to apply that test. The German and French mustards are an interesting mixture. They are a compound of cracker dust, mustard, cayenne pepper, white vinegar, oil and sugar flavoring. Old crackers were sometimes baked brown, then ground into dust and mixed with ground cinnamon and nutmeg, and the whole is sold for nutmeg at a price that drives pure nutmeg out of the market.

"Ground pepper is frequently sold for less money than the unground article, which makes the naturally suspicious suspect at once that the ground goods are loaded with pepper dust, which is made from coconut shells or buckwheat hulls, charcoal, white meal and mustard bran. Lack of taste is as desirable in an adulteration of spices as adaptability of color. For that reason the coconut shell ground up very fine is desirable. Venetian red, salt and white meal can be ground together and made into a valuable addition to cayenne pepper. A dull red pepper exported from Africa, is often heavily adulterated with that mixture. It is worth only about 10 cents a pound when pure, but when well adulterated it can be sold to a green dealer and a green trader for genuine Natal pepper, worth from 25 to 35 cents a pound. You can buy ground ginger at almost any store for 7 cents a pound, when the unground article commands 10 cents for the same quantity. That means that the goods offered for 7 cents a pound is a mixture of white meal, starch, cayenne pepper and manila rope, flavored with ginger."—*Oil, Paint and Drug Reporter*.

Is not all this horrible and suggestive of the application of the lash?—*Ed.*

TRIAL OF WATER-LIFTS AT SAIDAPET FARM.

On the 1st instant a trial of water-lifts, *viz.*, the Picottah, the Sing'e Mhote, the double Mhote, an Improved Double Mhote, and Subba Rao's Water-raising Inclined Plane, was held on the College Farm, Saidapet. The other gentlemen present first watched the working of Subba Rao's Water-raising Inclined Plane. This consists of a very abrupt slope fitted with wooden rails, on which a truck moves up and down, the ropes of the bucket being fastened to the truck. The top of the truck on the slope is always horizontal. The water-lift is worked by a man and bull, weighing 640 lb., getting into the truck, which then moved down to the foot of the slope, raising a bucket, with 30 gallons of water, 17½ feet high. The man and the bull then stepped over a platform and walked to the top of the slope by a path 42 feet long, which the bull took 30 seconds to ascend at the rate of about one mile per hour. As soon as the man and the bull got out, the truck was rapidly drawn to the top of the slope by the empty bucket which was let down loaded to half the weight of the truck. Mr. Lee Warner and other gentlemen watched the work of the water-lift for twenty minutes, 23 buckets being raised during that time. In the evening the water-lift was again worked for half an hour, during which time 36 buckets, each shown to discharge 30 gallons of water, were raised. About 70 buckets, or 2,100 gallons of water, were thus raised per hour. If, as suggested by many of the spectators, a bull and a man were made to descend the slope in the truck, while another bull and man went to the top of the slope, the efficiency of the water-lift would be more than doubted. The water-lift does not cost more than R20, and can be constructed by any village carpenter. Certain suggestions for providing control over the speed of the descending truck were made.

The Single Mhote which is the ordinary water-lift of the country worked by a pair of cattle, did very good work at starting. It could not be worked for a sufficient length of time for want of water in the well. On Monday it was worked for 1 hour and 55 minutes in the morning and for 1 hour and 49 minutes in the evening in the presence of Mr. Cengul Rao, B. A., Mr. Thirumal Rao, B. A., Mr. N. Bhujanga Rao, a retired Tehsildar, and Messrs. Thiruvengada Charriar, Balasubramania Aiyar and Rangiah Naidu, all landholders. The best pair of cattle on the Farm whose value was estimated by the judges at not less than R100, were employed. The total number of buckets (30 gallons each) raised in 3 hours and 44 minutes was 290, which is equivalent to about 77 buckets, or 2,310 gallons per hour, 19½ feet high. Both on the 1st and 2nd instant the public were shown how tiresome it is for the cattle to raise water by the Single Mhote, for nine robust coolies could hardly raise a single bucket of water, whereas two students of the Agricultural College, with no more difficulty raised a bucket containing twice as much water by means of the Improved Double Mhote. The Picottah and the Double Mhote were worked on Tuesday in the presence of the same judges except that Mr. Ragnarthia Charriar, B. A.; took the place of Mr. Balasubramania Aiyar who was absent. The Picottah, worked by three men, raised in 63 minutes, 228 buckets containing 7 gallons each, or about 1,519 gallons per hour. The Picottah was then stopped as the water level had sank too low.

The double Mhote (cost about R150) was worked by one of the two bulls employed at the Single Mhote. In 100 minutes it raised 132 buckets of 30 gallons each, equivalent to about 79 buckets or 2,370 gallons per hour. The Improved Double Mhote (cost about R60) raised per hour about 60 buckets of 46 gallons each, or 2,760 gallons per hour, and would have raised much more but for the excessive leakage of the mouth-piece; it was worked, too, by an indifferent pair of the cattle belonging to the College Farm. It had one very serious defect, *viz.*, that as soon as the drum was unbolted after the raising of a bucket, the bucket was precipitated into the well with a great shock. This defect has now been re-

medied by Mr. K. V. Krishnasawmy Iyer, bailiff of the College Farm, by an ingenious contrivance whereby the force of the shock is utilised for raising more water, and perfect control on the speed of the descending bucket is secured. The Improved Double Mhote and Subba Rao's Water-raising Inclined Plane will be given another public trial when the weather permits. The expense of the irrigation match was met from subscriptions.—*Madras Mail.*

TEA CULTURE IN CHINA AND INDIA CONTRASTED.

The following is the first paragraph of a long article in the *Japan Mail*:—

We have very small hope indeed that the efforts which various Chambers of Commerce in China are making to place before the Chinese Government and people, suggestions which will enable Chinese tea growers to compete successfully in the markets of the west with Indian tea, will be followed by the desired results. These suggestions are all sound and prudent in their way; Chinese tea is weighted by *lekin* and export duties where Indian tea is free; Chinese tea merchants collect their goods in small quantities, allowing the leaf to remain untouched until they have a large chop, while most Indian chops represent a single day's picking the leaf being treated while it is quite fresh,—these and much else which will be found in the special reports on the subject from the Shanghai, Foochow and Canton Chambers are perfectly true. But they seem to us scarcely to go to the root of the matter. In China tea is grown by a large number of persons, each for the most part working his own little garden or plantation, aided perhaps, by half-a-dozen labourers. Nearly 40 years ago "Fortune," in his record of visits to the tea countries of China noticed that the plantations were very small. He says in all his travels he never saw one which would produce 600 chests, and not many which would produce 300. In India on the other hand the gardens cover sometimes thousand of acres; in Assam the average size of the gardens in the whole province in 1887 was between 800 and 900 acres, and the tendency is in favour of increase in size and diminution in number. On gardens of this extent the latest and most improved machinery is in use, large capital is expended, and every operation is conducted on a large scale with a consequent decrease in the cost of production. Capital and science are at work to attain the best results at the lowest possible figure. It is *la grande culture* against *la petite culture*; cultivation on a large against cultivation on a very small scale, American wheat against British wheat, Australian meat and wool against the British articles. Hence it would seem that to compete successfully against Indian tea growers all along the line the Chinese will have to adopt Indian methods, and in the agrarian condition of China this scarcely seems likely.

We quote the conclusion of the article:—

Of course the total export of Chinese tea is still far beyond that of Indian tea. In 1885-6 the quantities were 66 million and 144½ million pounds from India and China respectively; but Indian tea has to make its way in the United States and the continent of Europe as it has done in Great Britain. And seeing that it has progressed in the latter country by leaps and bounds because of its good qualities, and in fair fight with Chinese tea, there seems at present no reason why it should not in time succeed equally well elsewhere.

The Indian tea trade now gives employment to 500,000 persons, engages nineteen million sterling of capital, and the harvest of the current year is estimated as worth £4,500,000. In recent years the price has steadily become less and less as in the case of Chinese tea, and the tea industry in consequence is not so remunerative as in former years. This state of things the Indian planters have met by cheaper production by means of the production of machinery and other appliances by more rapid

and cheaper communication with ports of shipment by more care in expenditure and by co-operation. The fall in price is shown by the following figures giving the price per pound of Indian tea laid down in the London market and including the costs of sale:—1878, 1s. 5d.; 1882, 1s.; 1884, 1 1/4d.; 1886, 9/3d. per pound; when sold the profits in the same year were 1878, 1 1/4; 1882, 5/4d; 1884, 2/4; 1886, 2s. These naturally are the wholesale prices and Dr. White of the Indian Medical Service, commenting on them before the Society of Arts in London, said that they showed why China was going down in the contest with India. The latter working on a system centuries-old and on an exhausted soil is not able to reduce the cost of production materially, and meets the new state of affairs by supplying a lower quality so that it is now completely discredited, while India meets the reduced price by reduced cost of production. Indian tea of every grade fetches more in the London market than Chinese tea; the lowest priced Indian tea is more than the lowest priced Chinese, and the finest Indian tea fetches 2d per pound more than the finest Chinese tea. In fact Indian teas are constantly used to mix with Chinese tea in order to give the latter "body," and were it not for this mixing considerable quantities of Chinese teas now coming on the market would be quite unsaleable.

Into the subjects of the various qualities of Indian teas or the reasons why they are not yet so common on the continent of Europe as in Great Britain, it is unnecessary to follow Herr Festenmehl. Enough has been said to show the conditions of the great tea question which is having such influence on the trade of China and which appears destined to exercise a still greater and we might say destructive influence in the near future.

THE JUTE CROP.

Bengal and Assam are, it is believed, the only two Provinces in India in which Jute is cultivated as a fibre. In other parts of the country the plant is found growing wild, but it is rarely cultivated, and then only as a pot-herb. In Bengal, where the principal seat of cultivation is in the northern and eastern districts, with small patches in the central parts of the Province, the seed is sown from the middle or end of March to the beginning of June, and the plant is cut down from the middle of August to the middle of October, or in some districts earlier. In Assam, where jute is grown to a more or less extent all over the Province, Coolpoor having by far the largest area, the sowing takes place in March and April, and the cutting in August and September. The following figures, showing the percentages of exports in each quarter to the total exports, indicate pretty fairly when the produce of each Province comes into the Calcutta market:—

	Quarter ending			
	31st March.	30th June.	30th Sept.	31st Dec.
Bengal	17	1	33	46
Assam	38	4	1	51

	Area. Acres.	Outturn. Cwt.
Bengal	1,275,000	13,757,000
Assam	16,000	170,000
Total	1,291,000	13,927,000

It appears to have been figured out on the prospect of this season's crop in Assam. As regards Bengal the Provincial Director of Land Records and Agriculture states in his report up to the middle of August last that the crop, at first expected to be an excellent one, has in many districts deteriorated from drought in June and from daisy rust in July. He adds, however, that "considering the large amount of cultivation and the favourable prospects of a good sleeping season on account of the late rain,

it may be expected that the outturn of the jute harvest of 1888 will not be much below the average of past seasons."

Upon the basis of the figures given in the table appended to the Director's Report, an attempt may be made to frame an estimate of the probable outturn of Bengal jute for this year. As, however, these figures themselves are candidly stated to have no pretensions to statistical accuracy, the result must be taken for what it is worth. The average outturn is reported to be a little more than 15 maunds (nearly 11 cwt.) per acre. The figures then will work out thus:—

	Normal.	1888.
Area. Acres.	1,275,000	1,435,000
Outturn. Cwt.	13,757,000	10,990,000

There is an increase of 12.5 per cent in the average as compared with the normal area, but a decrease of 20 per cent in the estimated yield of 1888. This decrease hardly supports the Director's anticipations that the total outturn of this year's crop will not be much below the average. The rise in area under jute cultivation is, no doubt, correctly explained by the fact that the good prices which the growers have received during the last few years have induced them to increase the cultivation. But it is not altogether satisfactory that more precise information should not be forthcoming on a subject which is so closely connected with one of the largest and most speculative industries in India.

Assam exports about half its produce, all to Bengal and apparently nearly all for shipment. Broadly speaking, Bengal consumes three-sevenths of its produce and exports the remainder. The exports of raw jute from Bengal during the five years ending with 1886-87 to places outside it were as follows:—

	1882-83.	1883-84.	1884-85.
By coast, cwt.	59,500	56,600	57,900
By sea, cwt.	10,341,000	7,017,700	8,368,600
By rail, cwt.	3,900
Total	10,400,500	7,074,300	8,430,400

	1885-86.	1886-87.
By coast, cwt.	23,200	20,200
By sea, cwt.	7,782,300	8,306,000
By rail, cwt.	26,800	20,000
Total	7,832,300	8,353,100

The jute exports by sea have naturally risen considerably during the last four years. In 1851-55 their value was 23 lakhs; in 1864-65, 321 lakhs; and in 1884-85, 466 lakhs. In 1887-88 the value increased to 603 lakhs, the quantity exceeding 21 million cwt. Practically speaking, Bengal carries on the trade; the shipments are from Calcutta and Chittagong in the proportion of 5 to 1 and chiefly to the United Kingdom and the United States, the share taken by each of these countries being 73 and 17 per cent, respectively, on the total exports. About a third of the exports into the United Kingdom, which is supplied almost exclusively by India, is re-exported to Continental Europe, which imports more largely every year with Dutch and other manufactures. A large proportion of the supplies which are sent to the United States is, it is stated, comprised of jute-cuttings and rejections, which are turned to account by the inventive Americans for the purposes of paper-making.

VEGETABLE PRODUCTS IN AUSTRALASIA.

The effect of low prices for universally. While we are trembling at the prospect of a "cutting" price and forgetting that the sack of flour was never so cheap as it is now, our fellow countrymen in the antipodes are showing anxiety, the amount of anxiety which is increasing, because the corn and other staples are paid at a low rate in the country, and if that is not enough, the market is open to a higher value it is even worse—in Greater Britain. Can Australia grow products worth anything but wheat and wool? These are the staple articles, those upon which much of the

wealth of the colonies depends, and it has become a matter of urgent public importance to the colonists that something definite should be done for the more profitable tillage of the fertile soil with which Nature has endowed them. There was, therefore appointed some time ago a Royal Commission on vegetable products to investigate the matter. This commission held fifty six meetings in Melbourne, besides visiting South Australia and had before them all sorts and conditions of men who were able to give advice regarding the cultivation of the soil and its products.

One of the main objects of the commission was to indicate to farmers how to use their lands to greater advantage in the cultivation of products now imported. Customs returns show that vegetable and animal products capable of being grown or manufactured in Australasia are imported into Victoria to the value of about six millions sterling per annum, and into the other Australian colonies to the value of about thirteen millions per annum. These imports include many drugs and allied products, which are shown by the official returns to amount to the following sums annually:—

Materials	Victoria	All the Colonies
	£	£
Oils, vegetable	96,164	287,814
Tea	668,472	1,668,517
Tobacco, including Cigars and manufactured and unmanufactured Tobacco	282,061	745,446
Mustard	19,073	65,570
Opium	41,651	142,570
Perfumes and Essential Oils	13,549	22,664
Starch	16,136	61,732
Resin	7,099	12,847
Lime Juice	2,585	10,460
Dyes	23,667	31,238
Arrowroot	998	7,885
Gum	4,992	16,732
Liquorice	3,455	3,824
Blue	2,579	23,668
Canary Seed... ..	1,392	3,780
Chicory	355	6,443
Gelatine	1,697	1,697
Glue	2,886	9,487
Honey and Beeswax	286	2,109

Of the chief items in this list there can be no doubt that oil, tea, tobacco, and opium-yielding plants can be grown in Australasia with but little trouble. In South Australia, for example, the olive has been successfully cultivated since 1851, and the samples of oil exhibited at the Colonial and Indian Exhibition were excellent of their kind. This is an industry which might with advantage be greatly extended, more especially as the manufacture of the oil is not so largely dependent upon manual labour as some other manufactures of vegetable products. Moreover, the market for pure olive oil is seldom overstocked, and if we were to judge alone from the prevalence and persistence of adulteration in this article, a pure Australian oil would be remunerative. The report by Dr. Trimen, which we recently published, contained a reference to the cultivation of tea in Australasia. There is little doubt that the climate is suitable for this plant, and the consumption of tea per head of the population is nowhere in the world so large as it is in Australasia; but there is one powerful deterrent to the extension of tea-planting in the colonies, and that is the cost of labour. Labour there costs as many shillings as pence are paid for it in China, India, and Ceylon; and these countries could, in spite of heavy duties, place tea on the Australian market at a lower price than it could be produced there. For the same reason the cultivation of the opium poppy has never become general. Mr. Joseph Bosisto has produced excellent opium on his estate, but he makes no secret of the fact that although there is an import duty of 1*l.* per pound on the drug, it is questionable if opium production could be made to pay in Australia. Cheaper labour the colonists can

get if they like, but they strongly object to the introduction of it in the shape of John Chinaman, and he is really the only coolie who could exist in the colonies. Tobacco is already grown in Australia, but if we may judge from the price which it fetches as compared with the imported article, viz., about one-half, it cannot be of high quality. Some attention to the cultivation of the herb and the harvesting of the leaf should, however, improve matters in this respect. Fairly good tobacco has recently been grown in England under proper scientific conditions; these conditions might be observed in the colonies, and, as they have the advantage of England in climate, the result there ought to be at least equal. In regard to these matters we find in the fifth report of the commission that a bonus for oil and opium production is suggested, and for tobacco-growing it is urged that capable experts should be obtained to instruct both growers and manufacturers. The licence-fee of 150*l.* for small factories is recommended to be reduced, and whole question of duty and excise should be carefully reconsidered.

The colonies, it is well known, yield some wattle barks rich in tannin, which are exported to Europe in large quantities. On the strength of evidence given before them, the commission recommend owners of poor lands to try wattle-growing as likely to be remunerative where other crops fail. The supply of wattle bark is failing, and the price has doubled within the last few years. The cultivation of the "Canaigre root," which has grown well at Dookie, and contains from 26 to 40 per cent. of tannin, is also strongly recommended; and the Council of Agricultural Education hope to be able shortly to distribute roots of the plant amongst the farmers.

Mr. Warrick has recently spoken of the cultivation of perfume plants in Australia, and he is of opinion that it would be likely to turn out successful. We learn from the report that the growth of perfume plants and the manufacture of essential oils and perfumes is successfully carried on at Mitcham, near Melbourne, and reference is made to the opinion of Mr. A. Piesse, whose experience in this line is sufficiently indicated by his name, and the fact that he is a son of the author of the "Art of Perfumery." Mr. Piesse gave evidence before the commission, and stated that "Victoria is particularly well suited for the production of perfumes." Apart from the native odorous plants, whose number is legion, the cultivation of the well-established favourites not indigenous to the country would be most remunerative.

Closely allied to this is the cultivation of fruit. Australia produces more of the succulent fruits than she knows well what to do with, so that it is not surprising to note that the commission have suggestions to make regarding the export of the ripe fruit and manufactures from it. We should think that much of this, which at present is allowed to go to waste or sold unprofitably, might advantageously be employed for the manufacture of fruit-juices—raspberry, strawberry, and the like. The demand for these is constant, and the supply of natural juice from European fruit is but a small part of the total consumed, most of the fruit essences being of artificial production. With proper means for concentration and preservation, the natural juices might be made in Australia on a paying basis. What the Australians have, in short, so successfully done in viticulture might also be done in arboriculture. In connection with this and other vegetable products, which the commission believe may be exported from the colonies, it is suggested "that action be taken with a view to the establishment of colonial markets in London, so that colonial goods would be shown to the best advantage, and the public would know where to go to secure *bona-fide* Australian goods of the best quality." This can only be done by private enterprise. "United Australian action," which is limited at most, probably means "official action," and this would result in a useless, unprofitable museum. For real results shops all over London are required, and if the capital and enterprise for these are forthcoming, Londoners will

buy readily enough if there is anything good to sell. But it is evident from the report that the metropolitan public are not the first to be educated regarding the value of Australian produce: The colonists themselves require instruction, and more especially the farmers, whose object hitherto has been to get a big farm and put into it the work and manures which are only suited for a little one. This has to be changed, and the farmers have also to be informed of what else than wheat may be grown in mother earth; therefore the commission strongly recommend the publication of a cheap edition of Baron von Mueller's work, "Select Extra-Tropical Plants for Industrial Culture and Naturalisation," which affords the fullest information as to the useful plants capable of being grown in Victoria, and specially indicating the more important and valuable of them. We trust that the commission's labours will bear good fruit, and that Australian commerce, and more especially agriculture, will be advanced by it, and will take a larger share in supplying the old country with many of the raw products for which we are at present dependent upon foreign countries.—*Chemist and Druggist.*

TEA AT NAGASAKI.—Consul Enslie in his report to Mr. Trench on the Trade and Shipping of Nagasaki for 1887 remarks:—Owing to the primitive and careless methods of cultivation and preparation in the surrounding districts, tea has virtually ceased to be an article of export, except to the north of China, which takes large quantities of very inferior kinds, ranging between \$4 and \$5 per picul. There were but small purchases at the opening of the year, and, though prices declined, the rise in sterling exchange prevented any advantage being taken of this fall, which was about \$2 in medium to fine, and \$1.50 for letter kinds.—*London and China Express.*

KESARI DAL.—The evil effects of the particular kind of vetch known to science as *lathyrus sativus*, and to the cultivator as *kesari dal*, have long been well, if not widely, known. The habitual use of the grain produces a peculiar sort of paralysis in both men and animals, affecting in the human subject chiefly the lower limbs. The evil results are, however, not universal, showing themselves in different degrees in different subjects, while some habitual consumers of the grain seem to escape altogether. To this fact, and to the ease with which it is cultivated, may be ascribed its continued use. *Kesari* will grow on heavy clay lands which will give no other crop, and when sown broadcast, after the retreat of flood-water, will give a good return, although the ground subsequently hardens to the consistency of a sun-dried brick, and splits into long deep fissures. It is commonly sown in rice land before the rice is cut, springing up among the stalks and yielding a crop in the spring, while the rice stubble is still standing. The ease and cheapness of its production lead to its extensive use for the payment of grain wages, with a corresponding perpetuation of its evil results. This being so, it is interesting to observe that a continental physician, whose attention was called to the effects of the same grain in the south of Italy, has been conducting a series of experiments with a view to the isolation and subsequent examination of the toxic principle. In the result an alkaline volatile liquid has been obtained from the seeds, which exhibits all the poisonous effects associated with the use of *kesari*. The importance of this discovery, if it is to be relied upon, lies in the fact that this liquid, being volatile, is not present in preparations of the grain, such as pressed cakes made at a high temperature, which were accordingly not found to be poisonous. If, however, such cakes were prepared at low temperatures they exhibited toxic properties, the heat used not being sufficient to drive off the poisonous principle. This seems as if it might afford an explanation of the enormousness of the effects of *kesari* on the people who habitually consume it. In any case the experiments referred to are well worth repetition in this country, where a large number of the poorest classes are compelled to eat *kesari*

during many months of the year. If a grain which is undoubtedly noxious, can be converted into a wholesome food-stuff simply by the application of sufficient heat in cooking, the fact ought to be definitely ascertained and made widely known.—*Pioneer.*

CANES AND STICKS.—In a lecture on cane umbrella handles, &c., Mr. Jackson of Kew stated:—From the East and West Indies, Singapore, Java, China and other eastern countries, are derived a great variety of sticks, principally, however, belonging to the bamboo and palm tribes. The sticks, as required for the workshops, are drafted from these immense stores; some are so crooked, that they require a great deal of straightening before anything else is done with them, and this straightening process is one of the most interesting and remarkable point. On the top of a very hot stove is a heap of sand, in which the sticks are plunged, and kept there till they have become quite pliable. The workman then takes the crooked stick while it is still hot and inserts it into a notch cut in a stout board, placed at an angle inclined from him, and bends and strains it, occasionally casting his eye along it to see that it is straight and when perfectly so it is thrown down to cool, and when cold it is quite rigid, without the slightest fear of it ever going back to its natural crookedness. In this way some of the most irregular and apparently worthless sticks are made to assume an appearance almost impossible, when we consider that the workman has nothing but practice and a well trained eye to guide him. Heat is a very important element in the manipulations of a stickmaker, and produces very different effects on the several kinds of woods, the degree of heat necessary to straighten one kind of stick being often sufficient to completely spoil another kind. The same power which makes a crooked stick straight is applied to make a straight one crooked, and so we find that the rigid stems of bamboos, partridge canes, as well as all the various kinds of English sticks which are required to be curled or twisted, are by the application of heat made to assume almost any shape or form. Thus we often see ladies' sunshade handles at the present time, especially those of bamboo or partridge cane, twisted and even tied into double knots.—*Journal of the Society of Arts.*

THE WORLD'S SILK PRODUCTION.—The following statement, which has been extracted from returns lately prepared by the Syndicate of Silk Manufacturers of Lyons, shows the world's silk production in each of the years 1884, 1885, 1886 and 1887, the figures being in kilogrammes (one kilogramme=2.204 lb. avoirdupois):—

—*Journal of the Society of Arts.*

Exports from—	Total for Europe			
	1884	1885	1886	1887
France and Spain	268,000	264,000	272,000	260,000
Italy and Austria	2,002,000	1,825,000	2,000,000	2,000,000
Total for Europe	2,270,000	2,089,000	2,272,000	2,260,000
Levant	700,000	625,000	677,000	700,000
Total for Eastern Asia	4,670,000	5,478,000	5,810,000	6,100,000
Total production	9,290,000	9,317,000	10,082,000	11,210,000

DRUG TRADE REPORT.

LONDON, September 20th.

ANNATTO.—There is no change in values, which remain very low. At today's auctions only a few lots Ceylon seed were offered, 2d per lb. being paid in some instances.

BAEL FRUIT.—Ten cases shrivelled dried apple, slightly wormy, were bought in at 4d per lb.

CARDAMOMS.—The auctions today included 94 packages of rather better quality than the usual average. There was a steady competition, and the bulk sold at full to 2d dearer prices for the better lots, but occasionally cheaper for more ordinary parcels. Mangalore, smooth bold pale, 2s 7d; fair heavy "COO" brand 2s 4d; medium ditto 1s 9d; small pale 1s 2d per lb. Ceylon Malabar, good bold heavy pale but warty 2s to 2s 2d; ditto, yellowish 1s 11d; medium, plump pale to yellow 1s 6d; fair grey 1s 5d; skinny and specky brown 1s 1d; small long yellow 1s; ordinary 10d to 1s per lb. Mysore, good medium to bold pale, long and plump mixed 1s 11d to 2s; fair medium rather warty 1s 7d to 1s 8d; fair bold smooth being 1s 6d to 1s 5d; small pale 1s 1d to 1s 2d. Dull Wild Ceylon 3d per lb. Seed 1s to 1s 4d per lb. The following are the figures relating to the exports from Ceylon during the period between October 1st and August 23rd 1887-8, 290,057 lb.; 1886-7, 302,066 lb.; 1885-6, 220,178 lb.

CINCHONA.—At today's auctions there was a pretty large show of South American Calisaya bark, partly of the thin cultivated "imitation flat" bark, which did not sell, and some wild flat Calisaya, which is arriving in large quantities. For the latter, rather small and soft and somewhat damaged, 1s 7s was paid: a badly damaged lot fetching 1s per lb. Several parcels of Crown bark also sold at 9d to 1s per lb. for fair rusty quill. Next Tuesday's auctions are likely to be rather heavier than the average of recent sales, 3,151 packages being already announced, including 1,366 Ceylon, 381 East Indian, and 1,404 South American bark.

The *Tropical Agriculturist* estimates the world's requirements in Quinine and the supply of Cinchona from the Eastern hemisphere during the next four years as follows:—

	1889		1890	
	Exports Bark lb.	Average Standard per cent.	Exports Bark lb.	Average Standard per cent.
Ceylon ...	9,000,000	2	7,000,000	2½
Java ...	5,000,000	3½	6,000,000	4
India ...	2,000,000	2	2,500,000	2
Total	16,000,000	—	15,400,000	—

	1891		1892	
	Exports Bark lb.	Average Standard per cent.	Exports Bark lb.	Average Standard per cent.
Ceylon ...	6,000,000	2¼	6,000,000	2¾
Java ...	7,000,000	4½	8,000,000	4½
India ...	3,000,000	2½	3,000,000	2½
Total	16,000,000	—	17,000,000	—

	1889	1890	1891	1892
Quinine.	oz.	oz.	oz.	oz.
Required	7,500,000	8,250,000	9,000,000	10,000,000
Contained in total bark exports	6,500,000	7,500,000	8,750,000	9,500,000
Deficiency	1,000,000	750,000	250,000	500,000

It would have been more interesting if the *Tropical Agriculturist* had published at the same time the data* upon which its estimates are based, and it should be said that it is careful to add: there must, of course, be great uncertainty as to future exports from Java, and, indeed, from Ceylon; for no one can say how far a slight rise in the price of bark would tempt Ceylon planters to harvest in any one year, though, of course, the exports in later years would suffer in a corresponding degree.—*Chemist and Druggist.*

* All given in our Handbook.—Ed.

BARK AND COFFEE.

(From James Cook & Co.'s Monthly Despatch.)

LONDON, Sept. 20th, 1888.

BARK.—A much firmer market since our last, and the moderate supplies of East India have realized higher prices, generally about 2½d per unit for good qualities. For Quinine there has also been more enquiry, and considerable sales of German make at advancing prices, 1s 5d to 1s 6d per oz in bulk.

The large sale in Holland on the 30th August, and which comprised 500 casks, 2,300 bales Java Bark, much of it very fine quality, ranging from 4 per cent up to as high as 11d per cent quinine, went off at full prices.

COFFEE.—The market on the spot 6s to 8s dearer. Good and fine qualities of colory sell from 82s to 95s, and fine to fine ordinary from 71s to 78s per cwt. There is a divided feeling as to the future, some valuable opinions incline to the idea that there must be a marked advance throughout the present year, and that sellers of Rio, even for next Spring delivery at 53s or thereabouts, calculating on ample supplies, will lose money. The disorganization of labour has much to do with the delay, but more recently it is the rainy weather that has retarded receipts and the continued reduction in the stocks has favored the speculative movement for the rise, thoroughly in opposition to legitimate trade operations. Numerous orders lodged in Rio on the point of execution have been frustrated by the advance of 6s to 8s per cwt. in the Rio market.

Some ten years since stocks of coffee were in a moderate compass: 1879 started with less than 100,000 tons, but since then they have, until the last three years been accumulating.

	Brazil Season, Price, Fair		
	General Stocks	Rio and Santos	Channel
	Tons.	Bags.	Rio.

		Estimate 1888-9 6,500,000?	8 months }

In Caracas the crops promise well, early, as excellent in quality. The first parcel was expected in the market during September. The exports during August were 569,690 kilos; from La Guayra in July, 10,089 bags, and Pureto Cabello 10,764 bags. Guatemala also sends very favourable information with regard to the yield, which will be marketed early, but not quite as soon as was expected a short time since, Costa Rica decidedly small.

The quality of the first arrivals of new Java proved very satisfactory, but the further receipts from East Coast are described as being inferior. Of the Menado crop the Government estimate on the 30th June, was 6,300 piculs. The shipments of Java coffee, in parchment, for the year ending 30th June, was 86,881 piculs. The London imports in parchment continue on the increase, very little short of 80,000 bags having this season passed through the London mills, chiefly Costa Rica and Guatemala, but including some washed Rio, sold early in the month at 73s to 76s for good colory, leaving a substantial again to importers.

The Dutch sale on the 11th instant, 31,057 bags 708 cases, went off well at 2 to 4 cents advance. Good ordinary 43½ = 72s 9d per cwt.

The *Journal do Commercio*, the principal Rio newspaper, most trustworthy and careful in its statements, reports that the Rio coffee trees are said to have flowered well, and that the harvesting of the present crop is progressing favourably. The export to 15th September, is 387,000 bags, against 141,000 and of Santos 289,000 against 88,000.

The Continental Exchanges have been advanced swiftly, the receivers of coffee, September delivery, have the matter apparently in their own hands, and have put up prices considerably; but the fluctuations have been very severe, especially in Hamburg, from 79 pf. on the 1st instant, to 95½ pf. then to 185 pf., and to 250 pf.; subsequently sellers were found at 135 pf., more recently 110 was paid, and today's quotation is 72 pf. September, 67½ pf. October, 62½ pf. December, and 60½ pf. March.

It is impossible to fathom the mischief occasioned by the manipulation of the cornering in Hamburg; some restrictions are now being enforced, the Caisse, before recognising sales, requiring that Bills of Lading should be shown or shipments guaranteed, but this caution comes late, and may probably give more assistance to present holders of coffee for their operation than to those who have to deliver, the advance of the deposits in Havre to 100 fcs. per bag for September-October delivery, and 12 fcs. per bag for subsequent delivery, may also assist such a course. The movements are startling and losses serious; fortunately, a large proportion, it is expected, will fall upon outside speculators, but dealers are necessarily mixed up in the misfortune, and weakness is declared in Continental markets, as well as in London.

It seems a question whether steps might not be taken to lessen in some degree proceedings so detrimental to the regular trade. The Canadian Government, according to a paragraph some time since in the *Tan's* newspaper, recognising the evil, passed an Act making gambling in stocks and merchandize a misdemeanor, punishable by five years imprisonment and a fine, no doubt a very extreme course, and one would think, scarcely practicable.

Exchanges, though encouraging undue speculation, give a certain degree of safety by enforcing payment of deposits, and for importers purposes they have many advantages. Many who have been recent operators in Hamburg are more likely for the future to divert their attention to the London Clearing House, and if this could in some respects be remodelled, it would have more success than hitherto. It is a mistake that Brokers, or in fact any one, personally interested in the Coffee Trade, should be selected as directors. It seems to us also a mistake that the Clearing House should limit dealings simply to those who pay a subscriber's fee or pass contracts only through special brokers. As long as Brokerage is paid and deposits held the Clearing House retaining the option as at present of refusing the registry of contracts, is not their position secure? Another main point, which we think would add to transactions would be to admit contracts for smaller quantities than 500 bags, and allow, as in New York, the sale of Brazil Coffee, either Rio or Santos, unless specially stipulated by the contracting parties at the time, based upon three samples of Rio and three of Santos, disregarding altogether the term "good average," which is variable, and permitting delivery of either class of coffee, within a given limit, at a market difference.

NOTES ON PRODUCE AND FINANCE.

Mr. Consul Alabaster, of Canton, reporting on the subject of the export of tea from that port, says:—"The competition of Indian, and more especially of Ceylon tea is felt to some extent; indeed, in congeneric it is felt most seriously, but the art of preparing the finer-scented teas, for which Canton is noted, has not been acquired by the Indian planters, and so long as the quantity thrown on the London and American markets is not excessive, there is always a good demand there for it. It is worthy of note, also, that it seemed the general opinion of experts, at a meeting held to discuss the question, that the quality and flavour of Canton teas has not deteriorated during the past ten years at least, as is said to be the case at other ports; and although there has been some slight increase on the *Tea*, the power exercised by the Tea Guild has been able to prevent its being crushed like other articles of commerce by too overwhelming taxes. The merchants say that the extinction of the trade is merely a matter of time, and that unless the export duties and *likin* are very materially reduced, or abolished altogether, it cannot continue to compete with Indian and Ceylon teas; but in this I cannot agree with them. So long as the quality is maintained, the taste for good teas will continue, and although the commoner sorts used only for mixing will be supplied from this, there should be a good demand for the higher grades for many years to come."

The condition of the tea trade of Japan is not altogether satisfactory. The export figures for the port of Yokohama for tea showed a slight falling-off last season as compared with 1886, both in quantity and value, being 26,557,616 lb., valued at 7,732,315, against 27,836,925 lb., valued at 8,292,538, in 1886, or a decrease of 1,279,309 lb., and 497,120. The trade is described as having been an unsatisfactory one to exporters, as they had not only a somewhat inferior crop to handle, owing to the weather during the growth of the leaf not being so favourable as in the preceding year, but a considerable portion of the previous season's supply remained over on the American and Canadian markets, and as a consequence, the new leaf did not meet with the demand anticipated by some buyers. The result was, upon the Japan market, caused distress and lower prices for what remained of the crop, but the Japanese dealers kept prices up, and shipped a considerable quantity of tea in the present season, among several consignments for the purpose. These shipments having no legitimate outlet, and being thrown upon the markets from unaccustomed channels, were recklessly sold in the contract markets of New York and Chicago, and, as they served to increase the previous excessive supply,

they produced a depression and low range of prices such as had never before been experienced in the United States and Canada.

The correspondence on tea in the *Standard* has gone on now for a fortnight, and were all the letters received, published, it might go on for a year. Let us hope the readers of that paper have profited by the various opinions put forth. There have been one or two stupid attacks on Indian tea, and Ceylon tea has come in for some adverse criticism also, but, as a rule, cheap China and packet teas have had the lion's share of abuse. Those interested in the Ceylon tea trade have, as usual, been very wide awake, and have not lost an opportunity of scoring on behalf of themselves. In fact, at present, the whole controversy seems to have been carried on in their interest. We have noticed before that the good people who push Ceylon teas do not lose an opportunity of making a point.—*J. & C. Mail*, Sept. 21st.

HINTS TO CINCHONA-PLANTERS.

In October last we referred to a paper read at a meeting of the Agricultural Society of Bandoeng in Java, in which the question was discussed at what lowest sale price it would be possible to grow cinchona at a profit to the planter. At that period the price of bark had fallen to the lowest level yet recorded, and the question, "Does cinchona-growing still pay?" gave rise to the enunciation, in trade journals and circulars, of the views of experts, their consensus of opinion being that, at the unit then prevailing, the closest possible margin of profit had been about reached.

Mr. Berkhout, who read the paper in question, has published it in *extenso* in a Dutch-Indian planters' journal, and his advice to the Java cinchona-growers to conduct their operations upon a more systematic basis and sounder scientific principles than have hitherto been followed deserves the attention of others than his own countrymen.

Mr. Berkhout's principal aim is to impress upon cinchona-growers the necessity of learning to form as accurate an estimate as possible of the exact period at which it will pay them best to harvest their bark. That time, of course, depends upon several factors, partly of a speculative nature—such, for instance, as the unit value in Europe—but the tendency among planters generally has undoubtedly been to harvest too soon, and thus to overfeed the markets with young and imperfectly-developed cinchona, which, if left upon the trees for a few more seasons, would not only have increased in size, but also in alkaloidal richness. Unfortunately no statistics are yet available showing the exact progress, season by season, of all the Java cinchona plantations over a number of years; but Mr. Berkhout, in support of his thesis, quoted figures, partly based upon the working of a large plantation of *Ledgeriana* trees in the Preanger districts (South-Western Java), as typical of the average results which might be expected from a well-managed concern.

The figures are given in Dutch florins (12 florins=17.1) per bahoe, a Javanese superficial measure, and appear to be all based upon practical experience, with the exception of the unit value, which, of course, has been higher in reality than Mr. Berkhout puts it, a fact which only makes his results more favourable to the planter. The expenses of planting, including roads, buildings, cost of management, &c., would be 300fl. per bahoe during the first year, to which, at the end of the year, 30fl. would have to be added for interest at 10 per cent. on the capital invested. During the second and third years 50fl. would be annually expended per bahoe for repairing of roads, building, and all working expenses, the same then during the fourth year amounting to 20fl. per bahoe. At the end of the fifth year, therefore, a sum of 600fl. per bahoe (including computed interest at 10 per cent. per annum) would have been expended on the plantation, but during that time 10,000 lbs. of bark, amounting to 1,200 cwt. (1 cwt. being kilos. -1 cwt.), would be obtained. This bark may

be put as averaging 3 per cent. sulphate of quinine, and yielding a net amount (deducting 15c. per ½ kilo. for freight and sale expenses) of 252fl., at the rate of 12c. per unit. From the fifth until the end of the tenth year the plantation would require an annual expenditure of 36 fl. per bahoe for working expenses, &c., to which compound interest at the rate of 10 per cent. per annum must be added, but concurrently with this expenditure the annual yield and average alkaloidal richness of the bark increases considerably, although at the same time the unit value in Europe is supposed to fall from 12c. to 7c. per unit. The yield and alkaloidal richness of the bark obtained average as follows:—

Yield per Bahoe from Stripping.			
Fourth year	1,200½ kilos., assaying 3 per cent.,	unit 12c.	
Fifth	1,700 " " "	3½ " "	10c.
Sixth	2,300 " " "	4 " "	9c.
Seventh	3,100 " " "	4½ " "	8c.
Eighth	4,200 " " "	5 " "	8c.
Ninth	5,700 " " "	5½ " "	7c.
Tenth	7,500 " " "	6 " "	7c.
Yield per Bahoe from Thinning and Pruning.			
Fifth year	500½ kilos., assaying 2½ per cent.,	unit 12c.	
Sixth	620 " " "	3 " "	12c.
Seventh	740 " " "	3½ " "	9c.
Eighth	900 " " "	4 " "	8c.
Ninth	1,100 " " "	4½ " "	8c.
Tenth	1,350 " " "	5 " "	7c.

This typical plantation, therefore, during the first three years yields absolutely nothing; from the third to the end of the seventh year it is carried on at a dead loss, though the actual deficiency diminishes each year; but the profits during the eighth, ninth, and tenth years more than recoup the planter for his previous disbursements. At the end of the fourth year there would be a loss of 348fl. per bahoe, but from that time the planter commences to sent bark for sale to Europe, and at the close of the fifth year he only finds himself 303fl. out of pocket, which amount further diminishes to 183fl. after the sixth, and to 16fl. after the seventh season. The balance then turns to the right side, for at the close of the eighth year the profits are 436fl. per bahoe, 813fl. after the ninth, and 1,683fl. after the tenth season. Of course, the actual figures will vary on almost every plantation, and Mr. Berkhout's statistics are intended merely to illustrate the importance of not stripping the bark from the trees too quickly, even though the unit value should be on the decline, and to demonstrate that, even if the unit should fall below 7c. per half-kilo. (or 1 3-15ths. per lb.), a well-managed plantation of full-grown trees may still be carried on at a profit.

In the second part of his paper Mr. Berkhout urges cinchona-planters to carefully tabulate the cost and the yield of their trees year by year, and to divide their plantations in sections, each of which should be tabulated under a separate heading. It is not necessary to mark the limits of the various sections by paths, but bright-leaved shrubs (of which, perhaps, a profit may be made at the same time), should be grown between the plots as a line of demarcation. During the first three or four years the average height of the trees should be ascertained annually, and after that time the quantity of bark contained on the trees in each section would have to be calculated and checked at each succeeding seasons. This calculation is one of the most difficult problems in connection with cinchona cultivation, it being impossible to accurately estimate the quantity of bark on the trees by merely inspecting the section. The author, therefore, recommends that the ascertained results of different cinchona plantations in the island should be collated and published, and that these gardens, according to the size of the trees, their soil, elevation, &c., should be classified into several grades, so that a planter wishing to estimate the quantity of the bark on the trees of his own plantation may be guided by the ascertained results of other plantations situated similarly to his own. The calculations at present resorted to are not founded upon any sound basis, being generally arrived at in the following

manner:—In a plantation a large number of six-year-old trees, say 1,000, are stripped, and found to give 2,000 kilos. bark. The probable yield of another six-year-old plantation, containing 800 trees per bahoe, is then calculated by taking 800 times the average of the yield of the 1,000 trees already stripped. Such an estimate does not take into account that on soil where trees are planted too close to one another the proportionate yield of branch and root bark is less than where there is a considerable distance left between the trees, and also that trees at the border of plantations are always stouter than those in the centre.

Mr. Berkhout thinks that one of the best methods to estimate the proportionate yield of bark of two plantations will be found to be the following:—Given two plantations having trees of similar average height and shape, but the one containing 800 trees, averaging 9 centimetres in diameter at 5 feet from the ground, and 4-5ths centimetre average thickness of bark, while the other has 1,000 trees of 7 centimetres diameter and 3-5ths centimetre bark thickness, it is required to ascertain which plantation will yield most bark. To calculate this, imagine rings of barks stripped from all the trees at a height of 5 feet, and placed side by side in strips. Those of the first plantation would cover a superficial area of

$$\frac{9^2x}{4} - \frac{(9-2 \times 4-5ths.)^2x}{4} \times 800 = 1,65 \text{ square metres.}$$

and those of the second garden

$$\frac{7^2x}{4} - \frac{(7-2 \times 3-5ths.)^2x}{4} \times 1,000 = 1,21 \text{ square metres.}$$

It is only, Mr. Berkhout thinks, by managing their plantations upon scientific and carefully considered principles that the Java planters will be able, after a certain time, to gain that control over the cinchona market to which the extent and the richness of their plantations entitle them.—*Chemist and Druggist.*

SILK CULTURE.—Last mail brought us copies of Mr. Thomas Wardle's work on "Silk: its Entomology, History and Manufacture as Exemplified at the Manchester Jubilee Exhibition," which includes a large number of illustrative engravings; also a pamphlet with "Paper and Discussion on the Silk Trade of England and the Continent" read before the British Association by Mr. Wardle. Should any of our Matale friends wish to have a perusal of these works they are very welcome.

A NEW KIND OF FUEL.—If it be correct that Dr. Kauffmann has discovered a method of converting petroleum into solid fuel which burns slowly without smoke, and with only 2 per cent of cinder, petroleum stands revealed more clearly than ever as the fuel of the future. Dr. Kauffmann's method is very simple. He heats the petroleum, and mixes with it from 1 to 3 per cent of soap. When the mixture cools it solidifies in a mass, which looks like cement and feels like tallow. It is not stated whether the solid petroleum burns without smell. For domestic use that is indispensable.—*European Mail*, Sept. 21st.

PROSPECTS OF THE COFFEE CROP IN COORG.—The outturn of the Coffee Crop in Coorg for the season 1888-89 is estimated at 5,180 tons; the average annual exports for the last ten years having been 4,500 tons. The Commissioner of Coorg writes:—"The total area of Coffee plantations, European and Native, is 80,389 acres, of which 59,124 acres are actually planted: Of this area, 33,141 acres are held by Europeans, and forecast returns have been furnished for the bulk of these estates. The Native holdings comprise 25,983, for the greater portion of which no returns are obtainable. The present forecast has been based, as far as practicable, on the returns furnished, and for the rest a rough estimate has been framed, giving a total of 5,180 tons."—Government of India. Revenue and Agricultural Department, Simla, the 28th Sept. 1888.

PLANTING: FROM MATALE EAST THROUGH UPPER AND LOWER DUMBARA.

KELEBOKKA FROM THE TOP OF HOOLANKANDE—MR. GORDON REEVES' FINE TEAS—POENGALLA AND ITS FINE JATS OF TEA: MR. REID TO "MEND HIS WAYS"—DAMBOOLAGALLA AND ITS WELL-EQUIPPED TEA FACTORY—RELUGAS AND CABRAGALLA—ODELAMANA AND NICHOLA-OYA—WEWELMADDE—THE LARTIGUE RAILWAY AND ROAD FOR LAGGALA—HOW TO DEVELOPE MORE TRAFFIC FOR THE MATALE RAILWAY.

One of the most impressive if not most beautiful pictures of upland cultivation in the island during the "days of old" when coffee was in its prime, was that obtained from the top of Hoolankande estate overlooking the length and breadth of the Kelebobokka valley. As described in the "Handbook for 1859," "it is a perfect picture of green and undulating beauty, the framework being the lofty peaks and ridges of the everlasting hills: the blue sky and the rolling haze affording alternations of light and shade, which nature alone can bestow: which the most gifted painters alone can imitate." Emerging from the jungle, we fain would stay on the spot some time, albeit the shadows of evening are closing in, for the old familiar scene is well worth looking over. But, alas! how changed since 1859, or even 1864 when I first saw it. The framework of everlasting hills is still there; but the picture is one of patchwork rather than of a uniform undulating green. Tea has by no means filled up the blank created by the dying out of coffee, though when the young clearings mature, the old picture will be more nearly restored. Kelebobokka was always regarded as an exceptionally good coffee district, especially in its middle and lower divisions. The higher fields never did so well. Now, in tea, we should expect the reverse to be the case, and certainly for fine flavour and good prices Hoolankande tea will compare favourably with any other in the island. There can be no question that Mr. Gordon Reeves understands his business as a teamaker, for, though his exceptionally high average may be partly explained by the scanty gathering, so far, of less than 100 lb. made tea per acre, yet this cannot explain why others in the district not making more than 120 to 150 lb. per acre do not get as good prices. At the same time, even for the "finest plucking," anything under 200 lb. would seem too little, though, no doubt, it may "pay" with very fine prices and low expenditure. On the other side of the hill, Brae has shown—in its fields yielding up to 700 lb. an acre, and this season averaging all over an average of 500 lb.,—what can be done in the neighbourhood, and we have no doubt that year by year, the average yield for Kelebobokka will increase for a long time to come. The tea plant in these old districts takes time to get down to the "virgin subsoil" as the favourite saying goes.

Facing Relugas and Damboolagalla and passing over the shoulder of the hill into Cabragalla and Poengalla, we are on classic planting ground if any such can be spoken of in Ceylon. At every step we are reminded of old friends: Tytler and poor Sangster Martin, Catto and A. H. Baillie gone to their rest; while R. J. Mackay, Chippindall and Stewart Jolly are still to the fore, we are glad to think, to read how their old "totums" are being revived into prosperity with tea. For one of the best and most uniform jats of tea in the country—a perfect picture of vigorous young plants of a high-caste type,—commend me to Poengalla, the property of

Capt. Boyle, R. N., whose son is a young officer in the Battalion of Gordon Highlanders shortly expected in Ceylon. Good careful planting might be expected with Mr. George Reid as Manager, and he had the advantage of "Logie" placing at his disposal a full supply of the best Seaforth and Horagalla seed. The result of putting out only strong vigorous plants is seen in a better, because more uniform, display of jat than I have hitherto observed on any clearings of the same age in the country. Now that the indispensable, all-important work of planting is finished, I have no doubt, Mr. Reid will find a little time "to mend his ways," at least in the direction we entered from Kelebobokka, a descent on which road enabled us to do penance for past misdoings as much as any poor sinner travelling to the shrine of his patron saint, and who may have forgotten to boil the peas in his boots. No need for peas inside, coming down that corner of Matale East! But what are such trifles when compared with the brave sight of promising tea fields on every side offering a cure for sore eyes, and despondency about the fate of old districts, and the hospitable welcome awaiting the visitor in the bungalow. This division of Matale East can not only boast of some of the best tea we have seen, but if half we heard be true, it has on Damboolagalla (Mr. Joseph Fraser's plantation) a model factory with tandem waterwheel and all requisite rolling, drying, &c. machinery admirably arranged. On the opposite side of the valley we glance over the young promising tea fields of Odelamana and Nichola-o-ya, and farther down we pass through a splendid sheet of tea on Wewelmadde which in this new product will no doubt repay Messrs. Moir and Hadden for the high price they gave for the property a few years ago, on the faith of being handsomely remunerated by large coffee-crops. Now not a coffee bush remains, and very soon, a cup of coffee in an estate bungalow on the Matale ranges will be a thing unheard of, unless the housekeepers take to importing the fragrant berry from London, as is already done by more than one up-country Ceylon resident!

The success of "tea" in the fertile valley of Matale and alongside the course of the railway nearly all the way to Wattegama is almost entirely a question of rainfall, the soil being very suitable. I confess to having learned with regret of the extent to which in some parts of the Northern districts, both cardamoms and cacao had been, and were being cut out, to make room for the more popular tea.

The several routes proposed for the Lartigue Railway across the valley from the town to the Eastern ranges were pointed out to me, but as already stated, I consider that the necessity for beginning at the end of either the Rattota or Kandanuvara cart road seemed much greater. Two points which ought to rule the projectors of any form of transport relief in the Matale district are very clear, namely, that any rail line or new road should serve to concentrate, and if possible bring new traffic to the Matale railway line; and secondly, that the endeavour should be to give early relief to the estates at present not served by a cart road. If the first instalment of a Laggala road is to pass on above Hoolankande and down by Brae, it ought surely to join with the end of the Kandanuvara road and so serve to place all that neighbourhood in communication with the Matale railway station, in place of some of the Matale East estates as at present sending their produce by the Madulkele road all the way to Wattegama. Catching such traffic for Matale should recoup Government for any outlay on the road. It is quite evident to old residents in the

district that if the Matale Railway were in the hands of a Private Company, a good many sources of traffic at present untouched, would speedily be tapped by the offer of special rates of freight. "Fruit" in great variety—we have never tasted such delicious loquats as on Poengalla, and the Matale Valley generally is famous for its fruit—could so be secured for trains that are now not laden nearly enough and other minor products would also help a good deal.

DAYS OF OLD WHEN KELEBOKKA, KNUCKLES AND RANGALA WERE "HAPPY HUNTING GROUNDS"—SPLendid TEA ON THE KING OF KANDY'S HIGHLAND GARDEN—TIMBER AND FUEL ABUNDANT GENERALLY IN THE NORTHERN DISTRICTS—LANDSLIPS IN 1888, AND IN 1885 AS DESCRIBED BY MAJOR FORBES—MR. ANDREW NICOL SENDING RANGALA COOLIES FOR RICE TO KANDY FORTY YEARS AGO—A VISIT TO THE DUMBARA VALLEY: MR. VOLLAR'S TOBACCO FIELDS AND CURING SHEDS—EXPORTS OF TOBACCO AND THE TOBACCO SYNDICATE—TOBACCO IN DELI—DUMBARA VEGETABLE MARKET.

In "days of old" before the British conquest the forests and highlands of the country now known as the Kelebobokka, Knuckles and Rangala planting districts must have been the happy hunting ground of the Kandyan Chiefs and their retainers who occupied the wide extending, cultivated Lower Dumbara valleys. In the same way on the other side of the country, the Kandyans of Kotmale were in the habit of migrating for two months at a time to live on the Lindula and Agra patanas and hunt the wild deer in the "Wilderness of the Peak." These undoubtedly may have been happy and profitable days for the native huntsmen in the "merrie greenwood;" but there can be no question of the greater good bestowed through the employment and food provided by the cultivation of these waste forest jungles, on thousands of Sinhalese as well as Tamils. On the borders of Kelebobokka, about the dividing line between it and the Knuckles, and overlooking those falls on the Hoolooganga recently immortalized in one of Boyd's stories in the *Literary Register*, there is a comparatively level expanse of uplands, known in Sinhalese legend as the King of Kandy's Garden or Highland Camping Ground. During all the coffee era, this comparatively level expanse remained crown property and grew up into low chena; but a few years ago the block was purchased by the proprietors of the adjoining estate (Allacolla) and as a young tea plantation on virgin soil, it is in a fair way to equal any clearing of the age in the country. Finer tea than the two year old on the flat could not be wished for anywhere of the age. As a general rule, tea on the old estates in the Kelebobokka, Knuckles and Rangala districts gets on more slowly than on the other side of Kandy and Nawalapitiya. But every year will see an improvement, until "bumper crops" come when the "virgin subsoil" is fully entered, and meantime nearly all the planters in these Northern districts have a great advantage over many of their brethren in Pussellawa, Dimbula, &c., in having an ample fuel supply available.

At the burst of last south-west monsoon, a Knuckles planter who had got his clearings in good order, only to find himself the victim of some very extensive and expensive landslips, penned to us a terrible and unmitigated indictment of Providence. He evidently felt like Dr. Jessopp's

Sussex yeoman that "Providence had a great deal to answer for," and that "the sooner One above Providence interfered and put a stop to his working, the better." Our correspondent, the Knuckles planter, probably thought that such an experience as his in 1888, was unprecedented; but we have come across an incident related by Major Forbes, which shows that even in his day, before planters had cut a tree in the Kandyan forests, similar catastrophe involving serious loss of life were not unheard of. We quote as follows:—

"In the last days of the month of November 1835, the rains exceeded in violence and duration anything of the kind I had hitherto witnessed, and did great damage in the south-western portion of the island. Soon after the commencement of this deluge, the thickness of the clouds, and the closeness of the rain, had contracted the visible horizon to a few yards around the house where I resided; and the darkness rendered it difficult to read at mid-day. Before the second evening every ravine was filled, and each streamlet had become a river in size, and a torrent in rapidity: down two of these, that passed my quarters, the dead carcasses of buffaloes and bullocks were rolling and tumbling; occasionally some one, still alive, and lately swept off, might be seen hurried along while still plunging and struggling in hopeless strife with the raging waters. The soil of the mountain near us, softened and saturated by the continued floods, had no longer tenacity to retain the great stones or loose masses of rock that rested on its steep sides and arched summit: they shifted, then rushed with resistless force, crashing through the forest, or thundering over the bare rocks until they reached the level grounds. So appalling was the continued darkness and the sound of falling rocks, that the villages along the base of the mountain were abandoned until the rain ceased, and the sun appeared, on the fifth day.

"On the fourth of these melancholy days, a man, lame and severely bruised, presented himself before me, and, pointing to the Hunasgiri range of mountains, groaned out that the side of a hill had shifted into the valley and entombed his wife and three children: his small property, his house, his garden, and his rice-field were also overwhelmed by the same catastrophe. His account of it was, that, while resting in the verandah of his house, he was awaked by an unusual noise, and could just distinguish, through the gloom, stones rolling past, and felt his cottage shaking from the battering of those that struck against it. He opened the door, alarmed his family, then fled; and had only advanced a few yards, when he perceived an immense mass of earth and trees and rocks pass over the house, which thus became the tomb of his family. The unfortunate man had received severe contusions from the stones that bounded down the hill, preceding the great body of earth borne forward on water that had accumulated in some crevice of the mountain, and produced the calamity. Great damage was done by this flood to roads, bridges, and rice-fields; the destruction of cattle was immense, and the loss of human life considerable, from accidents similar to that which I have just related.

"Amongst other changes caused in the face of the country by the rains, I saw a garden (in which stood several full-sized coconut trees) that had bidden farewell for ever to its owner's bounds, and now seemed perfectly at rest on his neighbour's property; a glorious opportunity for litigation, of which it is not likely two Kandyans would fail to take advantage."

Considering the settled well-roaded condition of the Northern districts now-a-days, it is difficult to credit the story of some of the drawbacks to

cultivation in the time of the early planters. Mr. Andrew Nicol—"the poor but industrious planter" and pioneer of Rangala—has just been telling us of the time when he had to send coolies into Kandy regularly for their rice supplies. He lost thereby three days of each man, taken up on the journey to town and carrying back for the long distance his burden of rice. The wonder is, under such circumstances, how coolies remained in the country at all. Nor was this all: they were liable to be pillaged by regular gangs of village robbers on some of the routes. In one case, a squatting village of Moormen had to be smoked out (without troubling the Government or the law courts!) before the Rangala and Knuckles coolies could pass unmolested: the said villagers for a long time levying a regular toll on every bag of rice passing by!

In Lower Dumbara—or Dumbara proper,—we had the pleasure during a brief visit to Pallakelly of being taken over Mr. Vollar's tobacco clearings, and no less than five large new fermenting, drying and curing sheds. The latter are very extensive, and plainly show that the preparation of the tobacco leaf in a state likely to attract purchasers at good or fancy prices, is no child's play. The fields with the fresh-looking tobacco plants with their large cabbage like leaves looked very promising, and it was satisfactory to learn from Mr. Vollar that so far from his old tobacco fields being abandoned, or becoming waste land, the flourishing young cacao shaded by luxuriant Ceará rubber trees we admired so much, were growing on the ex-tobacco fields of two or three years ago. To Mr. Vollar belongs the credit of bringing out Messrs. Schappe and Meyer to invest in tobacco in Ceylon, for it was his consignment of leaf from Dumbara that first attracted their attention hither. Mr. Vollar's first consignment sold at from 5d to 3s 10d a lb., the gross return being equal to some R400 per acre. The Syndicate began by purchasing Mr. Vollar's crop in store at a very fair price. Since then, they have planted on their own account and secured Mr. Ingleton's services; but unfortunately through the prolonged drought, their Kurunega venture this season, is not likely to be a success. In Dumbara there can never be any great extension of tobacco cultivation as there is no reserve of land available save what has been already cultivated as chena with "kurakkan" (dry grain) &c. The Syndicate would gladly take up 10,000 acres of land for their purpose if only it were available. As it is their biggest purchase is likely to be 700 acres in the Matale valley north of Rattota.

It will be interesting to see how our exports of tobacco increase during the next few years through European operations. We can generally distinguish such exports, because the large quantity of native grown unmanufactured tobacco sent out of the island, always goes to India. In 1885, two packages went to France; and in 1886, 40 cwt. to Australia; while in 1887, there is a return as follows:—"Unmanufactured Tobacco to the United Kingdom, produce of Ceylon, 273 cwt., 3 quarters 13 lb." valued locally at R7,600.

Of Mr. Vollar's consignments we learned in the early part of this year:—

Over 13,000 lb have gone home in 1887:

50 bales 15th March 1 cwt. each

77 " 4th July do. do.

The case is different with "cigars," of which the United Kingdom got a small package in 1885 and 228 lb. in 1886, while Australia got 110 lb. in 1885. In 1887, there were no Ceylon cigars sent to the United Kingdom, only 1 package to Belgium, 1 to British India of 50 lb., and 87 lb. to Australia.

For the expired portion of the present year, we are indebted to the Customs for the following return of our tobacco exports:—

Articles.	Countries to which exported.	Produce and manufactures of the colony.			Total.
		Pkgs. lb.	British, foreign, and other colonial produce and manufactures.	Pkgs. lb.

cigars ..	United Kingdom ..	— 177	— 330	— 507	
	Australia ..	— —	1 —	1 —	
— Unmanufactured	United Kingdom ..	— 8	— —	— 8	

It is interesting to know that the present is the Jubilee year of tobacco cultivation in Deli. We read in a Straits paper:—

"In May last it was exactly 25 years since Mr. J. Neinhuis, then manager of a tobacco estate in Java, started to Deli at the prompting of a syndicate at Rotterdam. There he laid the foundation of a colony which showed unmistakably what Dutch enterprise can do. The early years of tobacco growing in Deli certainly had the advantage of being exempted from the adversity and mischance, which, in spite of every precaution and care, too often prove fatal to planting operations in the neighbouring colonies. It must be admitted that fortune at the outset had singularly favoured Deli. Indeed planters there have had ever since an almost unbroken run of good luck. Much of the success and prosperity is undeniably due to the enterprising spirit of the early pioneers, who managed to overcome difficulties by determination and accommodation to circumstances."

No doubt, the great secret of success in Deli has been the production of tobacco leaf of an exquisitely fine quality. Of all crops, tobacco is the most exhaustive, and as the Deli planters do not manure—as the natives in Ceylon constantly do in their tobacco gardens—Sumatra may soon, like Java, be dotted with localities growing nothing but *alang-alang*, the *iluk* grass of Ceylon.

As a sign of the times, it was interesting to note in passing between Kandy and the Dumbara Valley, the establishment of a fruit and vegetable market at a point on the roadside some distance outside of Kandy, where the villagers sold their produce wholesale to dealers who came out from the town to meet them there.

TEA AND NEW PRODUCTS.—The substitution of tea gardens for coffee plantations has continued at an increased rate throughout the year. Bazaars again line the roads in every direction, and employment is being given to large numbers of contractors and artisans from the low-country. The yield of tea has been most encouraging. Cacao in Matale and Dumbara, cardamoms in Raugala and Madamahannura, and even old coffee in Bogawantalawa and Upper Dikoya, at the high prices which ruled during the year, restored somewhat of the old brightness of planting life in the Province. An interesting attempt was started in the close of the year by a German planter from Sumatra—Mr. Meyer—to introduce tobacco cultivation on a large scale. At my suggestion, he visited in succession Dumbara, where he succeeded, I believe, in inducing a planter of great local experience (Mr. Ingleton) to join him in his speculation, and then Matale, where he hopes to find a suitable block of land, and then the Seven Korales. Tobacco has been for years grown successfully on Rajawela in Dumbara, and I doubt not Mr. Ingleton was able to show him fine specimens of Ceylon-grown tobacco. He has not yet found any large block in Matale sufficient for his purposes, though Mr. Burrows is doing all he can to further his wishes.—*M. Slesinger's Administration Report.*

NEW AREAS OF CULTIVATION.

The Matala District was among the very first to feel the ruinous effects of leaf-disease and the other natural causes that wrought the destruction of coffee, until its very name became a synonym for decay and desertion; but it has also been among the first to take advantage of the introduction of new products; and its prospects from a planting point of view are now as bright as three years ago they were hopelessly gloomy. Abandoned coffee land is being put into tea on every side; and the prices fetched by Matala teas in the London market are a sufficient proof of the success of the experiment, as also is the large increase of goods traffic on the Matala line. It is almost impossible at present to form any accurate estimate of the acreage thus treated: it will be easier to obtain reliable figures at the end of 1888. Matala possesses advantages which very few other Districts can rival in the shape of splendid soil, a good supply of water-power for machinery purposes, and easy access to firewood, which give every reason to hope that this revival of prosperity is not merely temporary, but will be steadily progressive. Perhaps, however, the best reason of all lies in the proved energy and determined enterprise of the Matala planters. A great deal of new land has been, and is being, opened up for tea planting in the neighbourhood of Matala, notably at Ukuwala, Bandarapola, Balakaduwa, and Elkaduwa. There is not the slightest doubt that this area of new cultivation would be greatly and rapidly increased, but for the extreme difficulty (alluded to under III. 2) of ascertaining what land is available and what is not. There is hardly a planter in the District from whom complaints have not been received on the subject. It is not that there is the slightest desire to interfere with native rights: it is the utterly unsettled condition of these rights and claims at this critical time which affects detrimentally the interest of claimants and would-be purchasers. Surveys have been received in this kachcheri during 1887 of land applied for in 1879. The mere mention of this fact will show that there is some ground for the complaints of intending investors. The consequence is that there is a strong temptation to buy on doubtful titles without reference to the Kachcheri at all, which often has disastrous results for all parties concerned.

The area under cacao is steadily increasing, but more slowly than that under tea, as it is much harder to find suitable land. Every effort is being made to induce the native owners of small gardens in Matala south to plant cacao under the shade of their coconut trees and plantain trees, where it would flourish excellently; and some satisfactory progress has been made in this direction. But it will be two or three years yet before the natives generally see the advantage of taking to this product in place of their hopeless coffee. A great many of these gardens and a great deal of the chena land in Matala would also grow cotton and tobacco plentifully; and it is therefore to be hoped, in the interest of the District, that the Ceylon Spinning and Weaving Company, and the enterprise of Messrs. Meyer and Schappi—Sumatra tobacco planters, who are anxious to acquire a large grant of land here—will meet with the success they deserve. There is a great deal of land, too, in Lagala Pallesiyapattu (Matala east) which is admirably adapted to the cultivation of cotton and tobacco, and probably of cacao and coconuts.—*Mr. Burrows' Administration Report.*

TEA CULTIVATION A GREAT SUCCESS IN TRAVANCORE.

15th Oct. 1888.

Tea plucking—the average per cooly—has a wonderful influence on the imaginative man when away from his books. It is hard to know what is "the record;" but when one with a poetic turn is talking on the loose, he astonishes his hearers if he does not astonish himself, at the extraordinary deliveries his people do bring in. I heard of a man in the rising neighbourhood of Ukuwala who has had forty pounds a head!

That's not bad; and if he goes on at that rate he will upset your tea estimates. An unquestionable return comes from Maskeliya. Last week three hundred coolies brought in an average of twenty-seven pounds each.

It is said that Travancore is going to be the tea country of the world, and although Ceylon will be hard to beat, those who know the capabilities of Travancore are inclined to back it. What do you think of 400 lb. of made tea per acre from one and a-half to two and a-half year plants? "He must mean green leaf," is what the knowing ones here say, but there they are wrong: made tea is what is meant. Let him who is able to receive it receive it; to me it seems incredible. One thing is certain: that the tea growers of Travancore are going to go in for the best methods and the latest tips, and to get these they have in some cases sent over their native assistants to pick up tea work in the Ceylon factories. PEPPERCORN.

THEFTS OF COLONIAL PRODUCE AT THE LONDON WHARVES.

A most extraordinary revelation has just been made through the medium of the Thames Police Court which cannot fail to confirm many Ceylon planters in the bad opinion they have entertained of the management and disposal of their produce after being landed in London. It must serve, too, to awaken the suspicions of the entire planting community; and as the matter is one that eminently calls for the attention of our local Chamber of Commerce and Planters' Association, we give all the particulars available by the present mail. Perhaps the case will be one for the London Ceylon Association to inquire into; for it is clear that a great deal of rascality may have prevailed for a long time back, of which only a sample has now been presented to us. We have a private letter on the subject from a leading Colonial Merchant in the City who is as indignant as any planter can be, and who speaks his mind and indicates his suspicions rather plainly. We call attention also to the very commendable attitude of the representative of Messrs. Lewis & Peat in the Mincing Lane Auction Room (as reported along with the Police Case in another column); but we submit that it augurs a rather low tone among his surroundings when the offender was able to brazen the matter out, and more especially when Mr. Figgis's outspoken condemnation was not seconded by a general response in the room indicating that the offender should walk or be turned out? Be that as it may, it is quite evident that the present affair cannot be hushed up; for apart from the London Trade journals noticing it, we learn that *The Times*, *Daily News*, *Telegraph*, *Chronicle* and *Financial Times* have had references to the matter, and we are prepared in the *Observer* and *Tropical Agriculturist* to keep open the discussion as long as there is the slightest suspicion of a sufficient check not being applied.

It will be seen that the charge made against the Manager of the New Crane Wharf was one of stealing "gum" belonging to Messrs. Redfern, Alexander & Co., "guttapercha" of Messrs. Hettenbach Bros., and "coffee," "tapioca," &c., &c., of other importers, and of selling such produce on account of the Wharf Co. concerned. The most serious matter in our eyes is that one official after another connected with the Wharf treated the transaction as an ordinary one! Is it therefore too much to suppose that very many tons of colonial produce had been disposed of in the same way before it struck the Police to stop the two vanloads that form the subject of this charge?

When these two loads containing produce worth £200 are sold for £16, it is almost impossible to believe that either sellers or buyers considered it to be an innocent transaction; and it is most disturbing to find who was deemed hitherto "a respectable Mincing Lane Broker" concerned in so dubious a piece of business.

But irrespective of the question of the guilt or innocence of those mixed up in this charge, the whole affair must have a most important bearing on the late fierce competition between Docks and Wharves. One large London Dock Company had its receipts, we hear, reduced to a figure below its working expenses. Another large Dock Company has been reduced to a divided of $\frac{1}{4}$ per cent. The most wealthy Wharves have no doubt been in much the same plight: the poorer ones, of which there are so many up and down the Thames, must have had great difficulty in paying their way. How some of them have managed to pay their way at all has been a mystery to many outsiders. There are those who think now that much of the mystery is explained, when one man after another connected with a Wharf can take of the imported goods, vanloads and sell them or be parties to the selling of them not on account of the importer but on account of the Wharf! We hold clearly that the Wharves have no more right to the samples and sweepings than the Docks have. "Why, the London and St. Katherine Docks might make largely out of their big wool sweepings after one of their sales, but instead these are sold, and, of course, credited *pro rata* to the importers. But to have a Wharf with unlimited powers of sampling produce, the "perquisites in shape of produce of sales is too much to trust to any private concern." Such are the views of our London mercantile friend, and we fully concur in them. But we consider that the whole question and the general practice should now be most strictly inquired into.

A COLONIAL BROKER PUBLICLY
REBUKED IN MINCING LANE.

A very significant incident occurred at the drossaltery auctions on Tuesday (Sept. 18th.) Mr. Samuel Figgis, before communicating to offer the goods catalogued in the name of Messrs. Lewis & Pent, referred to "certain circumstances which had lately transpired in connection with one or two gentlemen, which, he considered, rendered it incumbent upon him to offer some plain observations. When persons assuming the title of 'colonial brokers,' and professing themselves capable to accurately value articles belonging to their trade, purchased such goods at figures very much below the actual value, and under circumstances of which they had all heard, the trade owed it to themselves as a duty to take serious notice of such proceedings. He offered to a case which had recently become public, and in connection with which the name was mentioned of one or two persons whom he now saw present in the room." Here Mr. Figgis, after blandly surveying the audience generally, looked at first more or less indistinctly, but gradually with much greater precision, to the right-hand side of the table below him, at which a number of gentlemen had taken their seats. Pointedly addressing some one in the extreme right-hand corner, Mr. Figgis stated that in his opinion a certain gentleman at that time present would do well to leave the room, and not be present in future at the auctions again, and that moreover, as Mr. Figgis's men had given the information in question, that they would never time has but again, in the course of applying procedure of the class of Mr. Figgis's observations, the auctioneer proceeding with his sale as if nothing had happened, and the person upon whom every eye had been fixed as the subject of the communication, continuing to preserve the air of absent-minded indifference

which he had maintained throughout the proceedings and entirely neglecting Mr. Figgis's advice to leave the room. The case which is supposed to have given rise to Mr. Figgis's remarks is reported below.

SERIOUS CHARGE AGAINST A WHARF MANAGER.

At the Thames Police Court, on Saturday last (Sept. 15th), Henry Kerr, of 31, Roland Gardens, Kensington, described as manager of the New Crane Wharf, surrendered to his bail on the charge of stealing goods belonging to Messrs. Hattenbach Brothers, of Fenchurch Street Avenue, and other merchants. Mr. Geoghagan attended; Mr. Thomas Beard, solicitor, watched the case for the owners of the wharf. A large number of merchants and brokers were present during the hearing of the case. The case had been before Mr. Lushington on the Saturday before, (8th Sept.) and on that occasion it transpired that at about 8-45 on the previous morning Sergeant Francis, of the Thames police, in company with Detective Bond, saw two loaded vans leaving the New Crane Wharf, Shadwell. The officers followed them to Assembly Passage, Mile End, the premises of Mr. George Dix, and there stopped the goods as they were being unloaded. At 3-30 on Friday afternoon one of the officers saw the prisoner at the wharf and told him that Inspector Read wished to see him. He said, "Is it about those sweepings?" and received the answer, "It is about the goods you sold to Mr. Dix." Kerr said, "Yes; I sold them on behalf of the firm. I am allowed to sign their name. I have not paid the money into the other office. Whether the money should be paid into there or whether it should remain here is a question." Mr. Kerr further stated in answer to the officer that he had no permit from Her Majesty's Customs to sell coffee or coffee-sweepings. Later on the officer, together with the prisoner, Mr. Priestly, a representative of the firm, and Inspector Read, went to Wapping and looked at the goods, which were then at the police station. Mr. Priestly was asked if he considered the gutta-percha and indiarubber and other articles were sweepings, and said that he would inquire into the matter. The prisoner said that some tapioca, sago, pepper, and ivory-nuts were the remains of samples, and the sum he considered sweepings. With respect to the coffee, he said that had dropped down through the floor and had been swept up. He did not know that any of it had gone out of the warehouse. He was then told the charge by Inspector Read, and was taken into custody. Mr. Ludwig Hattenbach, merchant, of 4, Fenchurch Avenue, said he had goods stored at the New Crane Wharf. On Saturday he was shown some indiarubber and gutta-percha goods at Wapping Police Station, which he identified. He did not consider them sweepings. Inspector Read said he saw the prisoner at the City office and told him he had detained two van-loads of colonial produce, which had been carted from the wharf and sold to Mr. Dix by him (prisoner) in the name of Cousins. Prisoner said, "I sold them by the firm's authority." Mr. Priestly said, "Yes quite right. I have given him authority to sell the sweepings." They afterwards went to Wapping and saw the goods. Witness said, "Do you call these sweepings?" Mr. Priestly looked at the prisoner and said, "How did this happen?" The accused made no reply. Witness said, "Have you advised the merchants to whom those goods belong that you were about to sell them?" Mr. Priestly replied, "No; we always sell the sweepings." Witness said he did not consider they were sweepings, and stated charge the prisoner with being concerned in stealing them. When the charge was read over to him he replied, "Am I charged individually? I sold them on behalf of the firm." The value of the two loads was over 200, and they were sold to Mr. Dix for 16. He had not had time to communicate with the other merchants interested in the goods. On the case being further inquired into last Saturday Mr. L. Hattenbach, merchant, said since the last hearing he had been to the Wapping Police Station and examined the gutta-percha

and indiarubber. The total value would be about 9%. He had other goods warehoused at the wharf besides these. He was shown some pepper and some sago, and he believed he had goods warehoused there similar in appearance and quality. He should not consider the gutta-percha, indiarubber, sago, or pepper as sweepings. By Mr. Geoghegan: He did not authorise the police to take the prisoner into custody. He had stored things at the wharf for many years. Samples were allowed to be sold, and often accumulated for months before they were sold. He could not say if the indiarubber and gutta-percha were his property. He did not prosecute in this case. Mr. Andrew Devitt, a colonial broker, of 6, Mincing Lane, stated he knew nothing about the affair. In answer to Mr. Sayer, chief clerk, the witness said he had seen some gum in the hands of the police. There was about 6 cwt. or 7 cwt. of it, and the value would be 10% or 15%. That quantity might have been made up of samples. He was a broker, and his merchants had gum stored at the wharf. The wharfingers might have the right to sell the gum. The gum changed hands every day. He acted as broker to Messrs. Redfern & Alexander, and they had gum at the wharf. By Mr. Geoghegan: Samples of gum would amount to tons in a short time. What he saw was certainly not sweepings. Samples were sold without the proceeds being accounted for to the merchants. George Morris, a sampler, of 42, Arabin Road, Brockley, stated he was employed at the Crane Wharf. He drew the samples from the packages including tapioca and gum. A clerk then came from the office and took them away. His name was Partridge, and he was clerk of the wharf. The samples were drawn by the prisoner's orders. He also drew samples of pepper, gutta-percha, and indiarubber. He should say the samples he drew were the property of the wharf. The goods that were seized by the police were entirely made up of samples and sweepings. Mr. Lushington said he could not help saying there was a good deal of unwillingness shown in the case by those from the wharf. Thomas Handley, foreman at the New Crane Wharf, said he delivered the parcels seized by the police from the wharf to the vans by direction of the prisoner. The parcels consisted of samples, and the whole of them came from the sampling floor. The coffee in the bag produced was mixed with dirt. He agreed with the last witness as to the accumulations of samplings. George Dix, a colonial broker and dealer in driersalt produce, of 9, Mincing Lane and 13, Assembly Place, Mile End Road, said he purchased a quantity of goods from Messrs. Cousins & Co. on September 4th. He made the purchase personally, and gave certain prices for particular goods. Prisoner told him the goods were sweepings. He received the invoice produced by post. On September 4th he paid the accused 46l 0s 10d by cheque, and made it payable to the New Crane Wharf. He should think the cheque was an open one. He believed he was dealing with the wharf, and he paid fair prices for sweepings. With the exception of that cheque, the prisoner did not receive any money from him. Mr. Lushington remanded the prisoner again in order that the police might communicate with the Public Prosecutor. He would accept the same bail as before, viz. two sureties in 100l each and himself in 200l for his re-appearance.—*Chemist and Druggist*, Sept. 22nd.

DRUG TRADE REPORT.

LONDON, Sept. 27th.

CINCHONA.—The supply of cinchona bark offered at Tuesday's auctions was considerably larger than that offered at any recent public sale. It consisted of

	Packages	Packages
Ceylon bark ...	2,288	of which 1,785 were sold
East Indian bark	663	do 535 do
Java bark ..	10	do 10 do
South American bark	2,649	do 726 do
Total ...	5,610	3,056

the quantity actually disposed of, thus actually exceeding that sold at any previous auctions this year. At the commencement, prices appeared to be slightly

easier, but gradually the competition became more lively, until it slackened again towards the close of the auctions. On the whole, the last sale prices were almost maintained, at least no appreciable change can be reported, and the unit is generally placed at 2d to 2½d. The following are the approximate quantities purchased by the principal buyers:—

Agents for Messrs. Böhringer & Sons	lb.	212,721
„ Auerbach Quinine Works		141,307
„ American and French manufacturers		117,970
Messrs. Howards & Sons	...	70,448
Agents for the Brunswick Works	...	45,735
„ Jobst & Zimmer's Works...		29,401
Mr. Thos. Whiffen	...	19,274
Sundry buyers	...	4,680
Bark unsold	..	394,655
Total quantity in sale ...		1,036,191

SOUTH AMERICAN BARK.—The heavy quantity offered was almost wholly made up of cultivated Bolivian Calisaya quills and Cuprea bark, no fewer than 1,714 packages of the latter, mostly of old import, but some of which has only recently been landed, being placed in sale. A fair proportion of this Cuprea bark was sold. 1883 import—Sound 4½d; damaged, 3½d to 4d. 1882 import—Sound 3d; damaged 1½d to 2½d. For a parcel of new Cuprea 4d was refused, 4½d per lb. being named as the price, while other parcels are held at 2½d to 3½d per lb. Two cases very long heavy quill, catalogued as Cuprea bark (imported via Hamburg), remained unsold, not even 1d per lb. being obtainable. For Bolivian Calisaya in quills good prices were paid. A new arrival of 45 serons, all damaged, part badly, sold in one lot at 1s 3d per lb., the highest price paid for any lot at the auctions; for another fine lot of sound quills 1s 4d per lb. was refused. Other parcels sold as follows:—Very bold split quill 1s; sound silvery, rather weak 9d to 11d; thin broken 5d to 7d; damaged 4d to 10d per lb. For a parcel of Pitayo bark (1880 import) of rather dubious appearance 3½d was refused. An offer of 3d was also declined for a parcel of Soft Columbian bark (1883-84 import) 3½d being required for this.

EAST INDIAN BARK.—The assortment was a rather large one and of good average quality, the bulk selling as follows:—Original chips, mixed with quill, partly damaged 2½d to 4d; fine ditto 7d; renewed sound 7½d to 8d; damaged 6d to 8d; shavings, good bright 4d to 4½d; branch 4d; and a considerable parcel of the well-known NCO brand shipped from Madras at 11d to 1s for fine renewed bright; and 7d to 10½d for smaller. Succirubra realised: Original chips 3d; renewed chips, quilly mixed, sound 4½d; damaged 3½d; root 3d to 3½d; renewed shavings 3d; natural ditto, dull 2½d; small bright quilly 3½d to 4d; quill, weak to good broken renewed 3½d to 7½d per lb.

OF JAVA BARK only ten packages were offered and sold at 6½d per lb. for Ledgeriana root and chips; and 4½d for long weak damaged quill. The next Amsterdam cinchona sales will be held on October 4th, and include about 330,000 lb. Java bark, of which about 275,000 lb. are quinine manufacturers' bark, containing about 185,000 oz. sulphate of quinine, or an average of 4½ per cent.

CINNAMON.—The upward movement in spices has affected this article, of which the stock is rapidly diminishing, and it is said that nearly 500 bales Ceylon have recently changed hands at an advance over the recent public auction rates.—*Chemist and Druggist*.

TEA IN AUSTRIA.

We have been favoured by Mr. Marinitzsch with the following Report on China teas supplied to the Trieste market and which cost there 1s 11d (for No. 3, valued at 1s 1d to 1s 5d) and 1s 6d (for No. 4, valued at 10d to 11d) respectively, wholesale. Trieste is a free port, but all teas sent inland pay duty on leaving the town. This anomaly is shortly to be done away with, and customs duty is to be levied on produce landing at Trieste, which will

no longer have the "free town" privilege. Mr. Gordon Frazer's Report on the China tea samples got out by Mr. Marinitsch, is as follows:—

J. D. Robinson, Esq.—Dear Sir,—Herewith I beg to hand you report on two masters, lapsong souchong, as compared with Ceylon tea:

No. 3 is a fine tea with true souchong flavor. Tea of similar quality could be bought here occasionally at from the equivalent of 1s 1d to that of 1s 5d according to the leaf, whether pekoe or pekoe souchong, but the identical flavor could not be actually matched in Ceylon tea.

No. 1 is very common, and the lowest price whole leaf tea offering on this market would almost at any time be of much greater intrinsic value. Just now this class of tea is very dear in this market, and it would not be safe to mention under 50 to 55 cents, or the equivalent in London of 10d to 11d per lb. This tea has no flavor, and is bought on the Continent on account of its bold style of leaf.—I am, dear sir, yours faithfully,

GORDON FRAZER.

Of course the retail prices of the above China teas in Vienna and elsewhere may be as high as stated by our travelling correspondent a little while ago.

CATERPILLARS ON TEA.

Mr. Sholto Skrine of Dikoya lately sent us some caterpillars caught on his tea, to get information as to their identity and habits. Mr. A. P. Green, to whom they were referred, writes very much to the point, as follows:—

"Larva of *Sophisa cingala*, Moore, fam. *Chalcosiide*. A blackish green moth with a yellow band of large spots across both wings. The larva feeds on *Lagerstrœmia* and other plants. The pupa enclosed itself in a pale ochreous cocoon.—Where numerous, and causing much injury to the trees, the caterpillars may be collected by hand and destroyed. For caterpillar attacks on fruit trees in England, Miss Ormerod ('Manual of Injurious Insects and Methods of Prevention') advises good drenches of soft soap and fish-oil, or soft soap and sulphur thrown powerfully at the foliage. Although remedies of the above nature might be found to have an unpleasant effect on the tea leaves, caterpillars are very susceptible to injury from wet and cold in their young state and when changing their skins; and strong syringing with cold water where at hand might be tried with good effect if done in the early morning. Caterpillars being generally night-feeders, soft soap could be used in the evening, to be washed off by a good drenching with pure water the following morning. Except where the boughs touch, the caterpillars can only travel to another tree by crawling up the trunk, and where the attack is severe, the surrounding trees might be protected by placing rings of some deterrent at the lowest part of the trunk, or on the ground round about it. A thick band of hay or straw, soaked in a mixture of tar and oil, that would keep wet and sticky for some time, would effectually prevent the caterpillars crossing it. If the attack is confined to a limited area, surrounding the whole with sand or ashes well sprinkled with paraffin and water would check their further progress. (See Ormerod, 'Injurious Insects,' &c.")

PEPPER, COFFEE AND TEA.

In my last article I dealt upon the cultivation of pepper. I shall, in this, attempt to show the great advantage resulting from the cultivation of this important commodity of commerce to the agricultural community in general, and to the rice cultivator in particular, who, from the precarious nature of the cultivation owing to the interference of the middleman, may be said to be in a state of pauperism. I might here state that pepper is no new commodity to the Siamese cultivator. Ceylon, in former times,

was one of the greatest emporiums of pepper trade. Owing to the strict monopoly established by the Dutch, and the consequent poor return to the cultivator, other countries that had better advantages took the lead, and Ceylon, at present, instead of exporting, imports a large quantity for home consumption. On referring to the Ceylon Directory, I find that during the Dutch period, the "pepper grown in Ceylon was sold at higher price than that produced elsewhere. In 1739 the Dutch exported 465,000 lb of pepper, the greater portion from the Kandyan provinces, where the harvest began in December and ended in April.....In 1813, the export of pepper was 195 and odd candelies valued at about 12,000 francs." Since then according to the Directory, there was very little export of pepper, although, here and there, pepper is still grown for home-consumption to a very limited extent. Even in the hey-days of pepper trade in Ceylon, we see Bertolacci blaming the indolence of the natives for not greatly extending the cultivation of the vine, which, according to him, will grow on almost any soil, and has everywhere forest trees to spread over it, forgetting that his own people contributed a great deal to the indolent habits of the cultivator. The decline of the tobacco industry of Jaffna, now reviving at a rapid pace, forcibly illustrates how monopolies and prohibited tariffs act prejudicial to the foster of the national industries. But, it may be asked, why the pepper cultivation was not extended after the British occupied the country. The reason is not far to seek. The extension of British Government into Ceylon was, in fact, co-eval with the progress of coffee enterprise. The vast amount of capital and labor spent in the country by the indefatigable planter, naturally led the native cultivator into the belief that he had in coffee what he lost in pepper. And he was not far wrong. The few plants that he reared up in the background of his homestead flourished under his paternal care, and brought him a handsome amount at the end of the year. He has felt, perhaps for the first time, the peculiar sensation incidental to the jingling of money, which was denied him before. He found in Coffee the *talisman* of his life. The cultivation of Coffee was, consequently, pushed on sometimes even beyond his means, to the prejudice of his paddy lands. But, what cared he, so long as the "almighty dollar" was in his hand. If his paddy failed, he could have hypotheated his coffee crop to the ever-ready "Chetty" who probably kept a rice boutique close to a Coffee plantation; and the "Chetty" found a good business in bartering rice for coffee. Things went on in this somewhat humdrum manner, undisturbed by any foreign agent, or, unruffled by any domestic enemy, until, alas! the domestic enemy in the shape of "*hemileia vastatrix*" began to wage war with the cultivation. The history of this terrible leaf-disease has become a thing of the past; suffice it to say that both the European planter and native cultivator became heavily indebted, according to their respective positions in society. The planter is again up on his legs, as he has tea to support him; but the poor cultivator is crippled. Attempts are being made by natives to introduce tea plants into their lands; but it can never take the place of Coffee. Unless the native has sufficient capital to open curing-houses, the cultivation of tea will be a precarious one. At present, if tea is cultivated near large plantations with curing-houses, there is profit; for the planter, is ready to purchase green leaves. But, if the European market is flooded with tea, and there is every probability of its being flooded, and prices consequently fall, the native cultivator will be entirely at the mercy of the European planter, who may, and will reject the green leaves to keep up the price. And the green leaves being a perishable commodity, the cultivator is sure to land in bankruptcy. But the case of coffee was very different there was very little curing, and the produce might have been stored up in the cultivator's barn, until a favorable opportunity arrived for sale. Pepper is a still less perishable article, and has always a ready market. And the pepper cultivator will be quite

independent of the planter, though I am not sure of the "Chetty." I would therefore appeal to the philanthropists of Ceylon, to encourage the poor cultivators to plant pepper vines in places where they can be profitably grown.—MALABARICUS.—Local "Independent."

PHOSPHATIC MANURING.

WITH SPECIAL REFERENCE TO BASIC CINDER
AS A MANURE.

In the year 1879 an improvement in the well-known 'Bessemers' process was patented by Messrs. Gilchrist & Thomas. It must be explained that in the manufacture of steel from pig-iron certain impurities in the raw material have to be got rid of in order to produce a good steel. Among these impurities one of the most important is phosphorus. This is owing to the fact that even a very small percentage of phosphoric acid in steel has the effect of rendering it brittle. The extraction of the phosphorus from the raw material was formerly, however attended with very serious difficulties, and had the effect naturally of rendering steel a costly article, inasmuch as only the purer kinds of pig-iron could be used for the purpose. By the introduction, however in 1879 of the 'Thomas-Gilchrist' or 'Basic' process, these difficulties were very largely overcome, and the employment of even such impure irons as the Cleveland (containing comparatively a large percentage of phosphorus) was rendered possible, and the price of steel consequently generally very much reduced. The process 'consists of submitting the molten pig-iron to a very great heat in a pear-shaped vessel (known technically as the 'converter'). This is open at the top, and is supported on hinges, which permit of its being moved so as to pour off the scum which rises to the surface at the end of the operation and which we may explain, consists of 'Basic cinder.' In the original process the sides of the 'converter' were lined with fire bricks consisting largely of silica. This process was known as the 'Acid' process. In the 'Thomas-Gilchrist' process, however, the sides of the 'converter' are lined with lime (dolomitic limit-stone being largely used) lime being also added to the pig-iron. An air blast is injected through the molten mass, and the impurities are burnt or oxidised as it is chemically termed. The phosphorus in the iron is thus converted into phosphoric acid, and uniting with the lime forms phosphate of lime, which rises as I have already said to the surface in the form of a scum, and is separated from the steel by being poured off.

This, then, is how the *Thomas slag* is obtained. It did not seem, however, for some years after the introduction of this ingenious process to have struck any one that this rich phosphatic bye product might prove a valuable addition to our artificial fertilisers. The result was that the *Thomas slag* was treated as another of the only too numerous valueless bye-products, which seem to be necessarily incidental to most of our chemical and other manufactures, and was allowed to accumulate in large quantities without being used for any purpose. In 1883 some short articles published in Germany on the subject were the means of first drawing the attention of the public to its importance as a manure. During the years 1884-85 numerous experiments were carried out on the subject in the same country and from then up till the present hour it has become more and more extensively used in Germany till last year, as I already stated its consumption amounted to nearly 800,000 tons.—*N. B. Agriculturist.*

ENSILAGE.

There is no doubt whatever that the system of ensiling green grass has received a wonderful impetus during the last few weeks..... We now find that no silo, no chaff cutter is wanted at all, and we shall, we hope, soon learn that no extraneous or mechanical

system of pressure is wanted. Pressure we must have, but, as far as possible, let that pressure come from the silage itself. As in the case of Stilton and of cream cheese, and as in the case of Tokay wine, let there be no extra pressure, but the weight of the material. Hundreds of farmers are wanting to make silage, but are afraid to begin, as they have heard so much of the various systems used, the importance of continuous pressure, and the regulation of temperature. Let them take our advice, backed up as it is by experience. First, then, take the grass fresh and wet, and proceed to make a round rick of it, very carefully shaking up the grass and thoroughly well trampling it down. Let two or three days elapse, and proceed as before, using the second addition of grass as a weight upon what was put in the first day. After another interval of two or three days proceed again, and as the stack sinks add yet more grass to it. When the process has been carried on for a fortnight, the stack may be 10ft. or 12ft. high, and it may then be best weighted by placing the elevator near it, and building a hayrick on the top. If well topped up during the intervals, so as to throw off the rain, so much the better.—*Agricultural Gazette.*

THE STANLEY-WRIGHTSON PATENT INDESTRUCTIBLE TEA CHEST.—We have to acknowledge the receipt of three or four circulars from Messrs. Charles Strachan & Co., Colombo, referring to these tea chests. We have no doubt the patentees will advertise what seems such a good thing.

PROGRESS IN NORTH BORNEO.—Referring to the last number of the *Herald*, from which we have already quoted freely, a correspondent writes:—

The *North Borneo Herald* of 1st August is very interesting, 1st.—The new contract with Holt's Line for a 600-ton steamer plying between Hongkong, Singapore and Sandakan, with another steamer of 130 tons running in connection between Labuan and Semporna; the most southerly port on the east coast. The large steamer has first and second passenger accommodation and also third, and runs every six weeks. Mrs. Dominic Daly gives a very interesting account of Sandakan market, especially noting the different varieties of fish, fruit, and the various nationalities selling and purchasing. A yearly taking of \$3,000 or R7,000 for stalls and licenses speaks volumes for progress in Sandakan. A suburban lot of 1 acre sold on the 18th July for \$255 or R560, upset price \$60. Padre Elton formerly in Dikoya is the newly appointed Episcopalian clergyman in Sandakan, the first representative of other than the Roman Catholic Church. The challenge billiards cup presented by ex Governor Treacher has been won this year by our Ceylon friend, Mr. Henry Walker. I notice another Ceylon man, Von Donop, among the players. On page 465 is recorded the good fortune of a Mr. Von Gogh who has made a profit of \$40,000 or R85,000 on a concession of 10,000 acres he has sold to a tobacco company. It is also recorded that a Mr. Vander Hoeven has already formed a company to take up his concessions of land on the Labuk River, receiving a sum of R56,000 for each and R112,000 in shares. As the editor of the *Gazette* remarks: "This is good business." The Remar estate has secured a crop of 442 piculs or 26 tons of tobacco from 42 fields of 1½ acre each,—53 acres. This tobacco will be sold in Holland in October, and the prices to be obtained are looked forward to with great interest. Immigration statistics in Sandakan are favorable for the month of June: 264 arrivals as against 95 departures. When the Holt Line steamer contract is fairly at work in September and immigrants are carried to Borneo from Hongkong and Singapore for \$5 or R10, there will be a great rise in immigration figures which will benefit the tobacco planters. An interesting meteorological memo is given by Mr. Walker, giving the monthly rainfall in the principal stations, which will be very useful for the tobacco planters. Curiously enough the east coast of Borneo seems still preferred by the tobacco planters of the new Ceylon, while in the old Ceylon the west coast is considered most suitable so far.

COLOMBO MUSEUM.

INTERESTING SELECTIONS FROM REPORT OF THE
DIRECTOR OF THE COLOMBO MUSEUM FOR 1887.

CONDITION OF THE COLLECTION.

I mentioned in my last report the great difficulties I was then experiencing in preserving the Entomological collection from the attacks of fungus. I find that sponges soaked in citronella oil and placed in the cases answer better than anything yet tried. As an example of the difficulty in destroying both mites and fungus, I may mention that in one instance in which a solution of creosote and benzine was poured upon the sponges, it was quite impossible to stand over the case, when opened, for some months afterwards, the wood work being apparently saturated with the fumes of creosote; yet not the slightest perceptible effect appeared to be produced either on the mites or fungus. The treatment at present adopted is as follows:—

I.—Every insect is bathed in benzine on being removed from the setting board.

II.—If attacked by mites at any time the bath is repeated.

III.—If fungus appears, it is touched with a solution of carbonic acid in benzine.

IV.—Sponges soaked in the best citronella oil procurable are kept in the cases.

If these precautions are adopted, insects gradually become proof against attack. There are some specimens in the collection between fifteen and twenty years, and many ten years old, which have been treated this way, and now give no trouble.

I attribute the virulent attack of fungus last year to the use of naphthaline, which, although largely employed in European Museums, certainly tends to keep the insects damp in this climate. In the other zoological cases and in the cases in the Ceylon Products Room it is, however, used with good effect.

ON COLLECTING NATURAL HISTORY SPECIMENS.

A great improvement has been made this year in transporting the insects collected. Ordinary tobacco or butter tins have a layer of naphthaline placed at the bottom, and over that a layer of cotton wool; the tin is then filled with alternate layers of insects and wool. Packed in this way they keep perfectly relaxed for a fortnight or three weeks, and can be posted to Colombo from any part of the Island. They can then be looked through, sorted, and set at leisure. This plan effects a great saving in transport, as it is no longer necessary to carry insect boxes, and setting boards; and it also enables any one who is willing to collect for the Museum to do so with very little trouble and no expense. I shall also be able to establish stations about the Island, from which insects can be received from month to month, and thus some light be thrown on their distribution and natural history. Unfortunately, the reduction of the transport vote has prevented this idea being carried out during the past year.

With regard to the marine fauna, my experiences during the last few years have lead me entirely to abandon any more attempt at using the dredge as employed by Naturalists in Europe, the Ceylon boat being quite unsuited to the work. I experimented at Panadure with a Naturalist's dredge, reduced to one-half the size with lighter arms and the scrapers made perfectly flat—a form lately adopted by Professor Agassiz in dredging in the Gulf of Mexico. This answered much better. But in consequence of the reduction of the transport vote, my opportunities for trying it were very limited. I also experimented with the Negombo trawl, which attracted my attention when stationed at Negombo some years ago. Unfortunately, I find that to make it work properly it requires a large Negombo boat and crew. Next year I propose trying the Euplestella dredge used in Fiji, and also a compound dredge and trawl of my own design.

NEW METHOD OF MOUNTING NATURAL HISTORY OBJECTS.
I have introduced a few alterations in mounting specimens. Small insects are mounted on glass circles by a process invented by Mr. Staniforth Green, and when necessary a drawing of the specimen, sufficiently

enlarge to show its character, is placed beside it. A number of small insects prepared in this way are now ready for exhibition; and a small collection of beetles accompanied by drawings has been purchased. There has been great difficulty in supporting the small glass circles on which the insects are mounted, all the cements used to fix them to the pieces of cardboard through which the pins are inserted having failed; Mr. E. E. Green has, however, invented a very simple spring clip, which has overcome the difficulty.

A supply of new bottles from Germany having been received, I have commenced remounting the collection of reptiles. A flat sheet of glass is placed across the bottle backed with cotton wool, which presses the objects against the glass, so that although the bottles are round, the specimens have all the appearance of being in flat bottles against a white ground, and they occupy a very much smaller space.

A collection of spiders, centipèdes, and scorpions is now being prepared. They are mounted in wooden cells lined with cotton wool. In this way the almost insuperable difficulties of cementing the glass covers is overcome, the objects are kept firmly in position; and although air bubbles cannot be entirely avoided, they are of little importance; the animals also are always available for inspection and are well shown against the background of cotton wool. The same method can of course be applied to all marine forms, and I hope next year to have all our star fish, echinoderms, and custacea exhibited in this way. A background of glass wool has a much better effect than cotton wool, but its price is prohibitory.

ON THE NEW METHOD OF PRESERVING SPECIMENS IN GUM AND GLYCERINE.

I detailed at full length in my last report the new method of preserving fish and many kinds of invertebrates by gum and glycerine, but I also stated that its use was limited on account of its excessive dehydrating effect, and also from the cost of the glycerine for mounting. I had tried from the first to overcome these difficulties by weakening the mixture, but with the result that if spirit or salt solutions were employed, the gum was precipitated, and if water was used a thick crop of fungus sprung up in a few hours. I found that even a mixture of glycerine and syrup of the same specific gravity grew fungus quite as rapidly as glycerine and water alone. The great rise in the price of glycerine during the past year rendered it impossible to exhibit any more specimens in this medium, to my great disappointment, as I found that on comparing fish that had been mounted for the last three years with fresh specimens of the same species, that no loss of colour could be detected. The preservation of the colour is owing entirely to the gum, for if a prepared specimen is taken and placed in any solution which precipitates the gum, the colour is quickly lost.

Darwin relates that he was fond of trying imbecile experiments, and, notwithstanding the teaching of chemistry and his own experience that solutions of gum will not mix with alcohol, I determined to try once more whether weak spirits could not be introduced in sufficient quantity to prevent the growth of fungus. The result of the experiment was, that I found that solutions of gum and glycerine are miscible with spirit in all proportions necessary for my purpose. It had never occurred to me to stir the precipitated gum which re-dissolves readily, and hence my previous failures. I can now obtain mixtures of any specific gravity necessary, and I am preparing snakes and frogs as quickly as I can procure them to take the places of the old spirit specimens.

The solution used for mounting specimens prepared in this way is syrup reduced to the necessary specific gravity by proof spirit. I cannot say whether the colours will last as long as they do in glycerine, as I have only had six months' experience; but so far the effect is the same. Budge's solution, which is said to be quite a perfect preservative, and the celebrated solution of Wickersheimer, for which the Prussian Government gave a large sum of money, have both been tried without success. Sea water saturated with bichromate of potash has been found excellent for hardening jelly-fish. * * *

TEA PLANTING IN ASSAM AND CEYLON :
A COSMOPOLITAN'S VIEWS OF MEN AND METHODS.

Mr. John Greig, junior, of the firm of Messrs. John Greig & Co., patentees and tea machinery manufacturers, Regent Works, Edinburgh, is at present staying in Colombo, and as a man who has travelled over and had practical experience in nearly every one of the tea districts of the world, we thought it worth while interviewing him. He first came out to the East in 1865, having previously been a mechanical engineer, draftsman, &c. Then he passed his examination as a civil engineer and came out to Bombay and Goa as an irrigation engineer in the service of the Hon. Rustomjee Jamsetjee Jeejeebhoy. He occupied this position for about two years, and afterwards was appointed general superintendent for another period of ten years. During this time he had a good deal of experience in the planting of various products in different parts of India. Then a Government notification appeared asking inventors to try their genius on a machine for cleaning China grass fibre, and a prize of £5,000 was offered. Mr. Greig entered into the competition, and went home to see his machine perfected, winning a prize of R15,000. He then went into the North of Assam as a tea planter for Major Eckford, R.E., and continued there for five years as general manager.

In answer to our interviewer Mr. Greig said, that generally speaking, the methods of cultivating tea in Assam are similar to those in Ceylon, with only minor differences. The growth is slower in this colony than in Assam for the greater part of the year. In the latter place they get a very heavy rainfall in March, April, May, June and July, and then it continues to gradually diminish till September. Then the cold season sets in, and the tea bushes begin to harden, and the quantity plucked becomes less and less every day, until the bushes are, to use a colloquial term, "shut up" about the end of October, the leaf being no longer soft and succulent. Consequently it is not worth plucking. November, December, January and February are nice months as far as the climate for man is concerned, but they are bad for tea flushing. When the tea becomes "shut up," then comes the time of preparation for next year. First there is the hoeing to be done, and it is deep hoeing, said Mr. Greig, compared to the practice in Ceylon. The hoes are about 9 inches long, and they are supposed to be dug to the hilt in the soil. Next the pruning. The top pruning is done by women with long curved knives. These knives are slashed across the bush, and owing to the shape of the knife and the slide of the cut it is cut quite clean. The stick pruning is done by men. Some of the stems are four or five inches thick on the indigenous gardens, and are often cut with an axe. The tea bushes throughout Assam grow much higher than in Ceylon and are trained broader. Then, of course, advantage is taken of the cold weather, when the tea is not flushing, to repair all the houses and roads. The bamboo trays for withering have to be renewed, and the matting for the floors and general purposes has to be seen to. No tea is plucked again till March or even April, but as soon as the rain comes then comes the flush. But the plucking varies in different parts of India. In the Terai and Darjeeling district they can go on plucking till New Year's day, and they do not begin again till May or June. They pluck coarser in Assam than in Ceylon, because they want to get off as much soft leaf from the bush as they can. This practice, unless the leaf is separated in the factory when it is in either a flat or a half-rolled

state, certainly reduces the quality, but it increases the quantity. Assam teas, as a rule, are stronger than Ceylon teas, the leaf being softer and more velvety. They also require less rolling. Both teas fetch much about the same prices now in individual instances, but it greatly depends upon whether a person goes in for quantity; or quality; of course quantity with quality is what they all want. But in Assam there is less attention paid to quality, provided they get the quantity whereas in Ceylon quality is more sought after. "Then when all our young teas are a little older we shall have the advantage over Assam," said the interviewer.

"Oh, no," continued Mr. Greig, "the quality is sure to go down when the quantity increases. Already it is seen that as soon as the quantities begin to increase the qualities go down."

In answer to further questions Mr. Greig said: "The machinery used is much about the same, but they get through a greater amount of work with fewer rollers in Assam. This is because each batch of leaf that is put to the machine is only rolled 20 or 25 minutes, whereas here they roll it an hour or one hour and a-half. In India they only roll till the leaf is twisted up. They have what is called a high-class hybrid in Assam, and that is a very soft leaf, and produces strong liquor without much rolling. The Ceylon people were not generally able to buy the pure indigenous seed because of their losses consequent upon the failure of coffee. In fact, a great deal of it is the common China plant. But they were fortunate in their poverty in getting that low class, because about that time flavour was more specially required. For the last 8 years flavour has been in greater demand. A low class hybrid gives the flavour, and they get the strength by longer rolling, which breaks all the cells, and gives out a stronger tea than it otherwise would do. In most of the estates in Assam there are some China tea bushes, except on the hills, and on the hills they are purely indigenous."

Continuing, in reply to other interrogations, Mr. Greig said it struck him that Ceylon planters let their bushes stand so long without topping that they got "shut up with crows' feet." The long hooked Assam knife was just the thing for taking off these crows' feet. They cut the bush as flat as a table. Mr. Greig does not consider that Ceylon estates are old enough for much stick pruning. The cells of the upright stems are still quite open, and he thinks that topping and quilling the bushes are all that is required for years to come. He thinks that many estates would be better if the ground were forked all over, thus raising the soil to let the air get in about the roots. All the Darjeeling districts are forked, and Darjeeling is a district exactly like the hill districts of Ceylon. There they find a great benefit from forking. In Assam, without hoeing, which serves the same purpose as forking in Darjeeling, the produce of the estates would be almost nil. As a rule neither of these things is done in Ceylon—only in one or two isolated cases. Mr. Greig thinks they also plant too close in Ceylon, and pluck too early. Instead of beginning to pluck when tea is three years old they pluck when it is hardly two; and thus keep the bush too much dwarfed.* He also thinks there is too much "grab" here. Our planters are in too great a hurry to realise their money. In planting Mr. Greig does not consider that they hole deep enough in Ceylon. If they would go in for large and deep holing in places where it can be done the cost would repay itself three times over. The lining of estates is

* In Assam the age is counted from the nursery: in Ceylon from planting out.—Ed.

also carelessly and irregularly done here as compared with Assam, but that no doubt is owing to their having to plant in the midst of coffee and also to their haste to recover from their former losses. The subsoil here, he would say, is better than in Assam. In Assam it is a clay subsoil, so that it requires more draining than the soil does here. There are a lot of Assam planters who believe that tea won't last long in Ceylon, because here they pluck all the year round, but Mr. Greig is not one of those who think so. The Assam men naturally think that because their tea gets five months' rest every year it will last longer than the Ceylon tea, which gets no rest. But Mr. Greig thinks that the sub-soil here is so good that it will last quite as long as in Assam. When he was here twenty years ago he could see from the road cuttings the roots of the coffee plants down in the soil to a depth of 16 feet, and he has seen the tea roots going down far enough to pierce the sub-soil. He has noticed that it is the custom here to cut the taproot, but his experience in Assam has been that if any part of the taproot is broken the plant dies. He always took care in Assam not to allow the taproots to grow too long in the nursery. Generally, if possible, they should be taken out whenever the taproot appears from the shell, and planted as soon as possible. This will prevent them from being broken. The Ceylon men have got the custom of cutting the taproots from the old coffee days. Such a practice is all very well for producing seed, but is not so commendable where it is required to produce leaf. The theory is—for seed, prune your roots, for by this injury nature will try to recover itself; and for leaf—feed the plant as much as you possibly can, and keep all the roots intact. Mr. Greig says he has seen a great deal of blossom on the bushes throughout the estates in Ceylon. That, he says, is very bad. He finds the blossom is on pure China bushes and low class hybrid, and when bushes blossom, they are not worth keeping for their leaf. It would be better to pull the plants up by the roots and put in another good lot.

Talking on he said he thought the *siam* *attans* and even the *persea* *dumans* were very much underpaid for their work; compared with Assam their pay was very much lower. But the health of the climate, Mr. Greig thinks, makes up for the deficiency in this respect. He would rather be in Ceylon with £100 less a month than in Assam. He does not think it is much cheaper living here, but there is this to be said,—that in Assam the proprietors of estates are more liberal than in Ceylon. One or two horses are always provided by the estate, and the manager is provided with two native gardeners and the assistant manager with one to attend to their vegetable gardens. All assistants, as well as managers, are possessed of at least one horse, and often a trap, at the expense of the proprietors. Then a European is never seen weighing green leaf in Assam as they have to do in Ceylon. An under clerk does it. There is no such thing as selling green leaf to factories in Assam. If there is a garden at all the planter makes his own tea. Central factories for the manufacture of tea were tried, but were found to be a failure owing to the heating of the leaf before it got to the factory.

Such were the principal opinions planted from this experienced planter. Mr. Greig, in a day or two will be going upcountry to Mr. Dickson's of Telukman, where he is erecting a large S. E. A. E. Central Withering and Drying Machine, and superintending the fitting of the whole factory with electric light. He has there working one of his bulk tea cutting machines and also his newest in-

vention made at the request of Mr. Armstrong, a simultaneous roller breaker and sifter on the rapid centrifugal principle which he has patented.

POULTRY FARMING IN CEYLON.

It is to be doubted if there be not a tendency, greatly to be deprecated, with our governing Powers, whilst they give special and constant attention to the subject of Irrigation, to entirely overlook many of those minor industries, a little aid to which would do a great deal to promote the well-being of many thousands residing in isolated settlements. The subject of one of these,—that of Poultry Farming,—has long been taken up at home, and although the promotion of this industry is there more due to private encouragement and initiation than to any direct action by the ruling powers, a great deal has been accomplished towards rendering more efficient and consequently more remunerative, the rearing of poultry by small households. The cases of England and Ceylon, however, as regards the duty of Government respecting such matters differ widely. At home, the population has long been out of leading strings, and the day for motherly interference has long passed by. In Ceylon, the autocratic Government has duties towards the many races and classes inhabiting it which do not attach to those of countries having a more advanced civilization. Every form of industry needs encouragement and development and instruction in better methods. It is useless to depute these altogether to local Societies such as our Agricultural Society. This body—if we may still refer to it—and kindred Associations are not possessed of the funds whereby useful aid and instruction may be conveyed to the great mass of natives who live isolated from European influence. But a very small outlay allowed to the Agents of the Government who reside in the centres of such communities, would we believe, do much towards inducing an improved character being given to the supplies which reach our central markets.

Now, taking as an instance the subject which we have chosen for this article, we would ask whether we should rest content with the very inferior quality of native-reared poultry with which our bazaars are supplied. What that quality is, is well-known to every European resident. Who is there among that class who does not occasionally,—may very often—exhibit temper at the wretched *fat* which as a rule furnishes the *propos* *résistance* both of our breakfast and dining tables! Can anything be conceived more miserable than the attenuated birds with which our appus too frequently furnish us? Arthur Grilde's traditional "beautiful bird" must have been a perfect specimen of plumpness compared to most of the fowls which we in Ceylon are compelled to devour. And yet improvement at least in that matter of plumpness is one that could readily be attained were our native suppliers better instructed in the right method of feeding, or encouraged to stock their farmyards with a better breed of birds. Round about our planters' bunglows, and in the vicinity of Nuwara Eliya and other hill stations wherein Europeans have amused themselves with poultry breeding, the effect of the introduction of new classes of birds is strongly manifested. But the main sources of supply, wherefrom our lowcountry bazaars are stocked, show no such improvement, and it is among these that, we hold, the heaven should be introduced and allowed to work. We know from personal experience that ordinary bazaar fowls confined to a narrow run and fed upon soaked refuse grain fatten rapidly, and to such an extent that it became necessary to greatly curtail the amount of food given the

birds becoming so fat that the result of their consumption was a bilious household. But we learned sufficient from our experiment to show us that if the system we tried were adopted with common poultry for a week or two before being sent to market, we should see in our bazaars very different specimens of poultry to that we are accustomed to behold. There is no doubt that the native farmers would readily act on such a hint were the wire-netting for enclosing small runs readily available to them at a small price. This can be bought in quantity at an almost nominal cost, and its distribution by the Government Agents, if judiciously made, might act as a great incentive to the farmers in outlying districts. The late Mr. Dyke of Jaffna did much towards effecting improvement in many agricultural matters in the north. At his own expense he purchased the finest stud bulls procurable, and the effect of the services of these—given gratuitously—is very visible in the finer class of cattle possessed by a good many farmers in the Northern Province.

But this sort of thing ought not to be left to private enterprise, or individual generosity altogether. The expense that was undertaken by Mr. Dyke should be borne by the Government, which in a colony like this has, as we have said, duties towards the larger sections of the population it rules over, which are not incumbent on the Governments of more advanced countries. The expense certainly of the maintenance of small model Poultry Farms at each Assistant Agent's station, to be directed by such officer, would be quite inconsiderable, while their results would soon be beneficially visible, not only in the improvement of our bazaar supplies but in the condition of the native farmers. Every egg distributed from improved stock would contribute towards such a result by the introduction of a stronger strain into our native poultry yards. The outlay would be a minimum and the result it a maximum of good. It would, however, we feel sure, be a paying concern were some enterprising natives to buy up the poultry from native growers and submit them to the form of temporary restraint and feeding we have alluded to, before sending them to the public markets. A stall always stocked with well-fed poultry would soon attract all the European custom, and this would readily pay the slightly enhanced price which could be justifiably demanded for improved supply. A protection would be afforded both to the seller and the buyer if a system of sale by weight of poultry could be established. At present, whether our birds be skinny, or as nearly approaching to good condition as is ever observable among them, we pay pretty much the same price for them. A discrimination insisted upon by the comptrollers of domestic households would soon tend to the improvement we desire to see effected, and were this seconded by some effort on the part of Government, a very much to be desired change might soon be brought about.

The freer use of incubators would certainly tend to aid the effecting of such a change. Our London Letter but recently drew attention to a specially useful form of these introduced by the wellknown Mr. Christy, the large drug importer of London. Here each model poultry farm,—which we have suggested should be established under the control of every Agent of Government,—might be supplied with some of these. The natives would soon appreciate their effect in the ready multiplication of increase, as well as the freedom from the liability of the egg to be destroyed by vermin which now contributes so greatly to reduce the output of native poultry rearers. The introduction of small poultry farms would be the thin end of the wedge, which

when driven further home by carefully measured degrees, would do much to bring about that improvement in the condition of the rural population of Ceylon which it is the prime duty of their rulers to try and effect.

PEARL FISHERIES OFF CEYLON, TUTICORIN, AND BORNEO.

Capt. Donnan, Inspecting Officer of Pearl Fisheries, goes off to the pearl banks on Monday morning in the barque "Sultan Iskander," to see if he can find any more of the oysters that were carried away from the Cheval in December last; which, however, he hardly expects to do, but still it is worth while making the search. After thoroughly searching in the vicinity of the Cheval, Capt. Donnan means to go down to the new bank off Dutch Bay, to see if the oysters that were on it in abundance this time last year have escaped the current which cleared the Cheval. If so he will lift and wash a sample, as it is just possible they may prove fit for fishing in March next. After examining the bank off Dutch Bay, Capt. Donnan means to run down to Chilaw and have a look at the banks in that neighbourhood: so that our worthy inspecting officer has work enough out to keep him away till the end of November. We trust his health may stand it all.

We hear that a big fishery is expected at Tuticorin next March, but it will be finally settled by the result of the inspection which Capt. Phipps will make within the next month. If we in Ceylon should have a fishery too at Dutch Bay, we may wonder which side would attract the most boats, divers, and merchants. One or the other would be bound to suffer some loss in consequence of the attraction of the favourite fishery.

While on the subject of pearls and pearl fisheries, we may mention that we received the other day some seed pearls sent from North Borneo. We should like to know the kind of oysters from which they were got, although, marketably, these tiny seed pearls are of little or no value. The oysters fished for them must be far too young. The North Borneo authorities meditate an experiment in transporting and acclimatizing Ceylon pearl oysters. But, before doing so, it would be necessary in the first place to try some experiments as to the best way of keeping oysters alive a sufficient time to cover the voyage from our banks to Borneo. We rather think this would be found a difficult matter.

THE LEBANON TEA FACTORY

is likely when complete to be one of the most noteworthy in the country. Mr. Dickson has just added to the group of estates served by this factory, the estate of Battagalla, so that the Lebanon group altogether will now cover 1,486 acres, of which 960 are planted with tea. To drive his machinery, Mr. Dickson commands a river which sends into his watercourse enough to drive a 60 horse-power turbine. In the factory there are, Kinmond's and Richardson's, a Barber No. 1 and Jackson's Excelsior as well as Universal rollers. Mr. Dickson is well pleased with Kinmond's and Barber's for use with the first roll, transferring the leaf thence to the Excelsior and Universal to finish off. In this way, he considers time is saved and better work done. The factory includes Jackson's Victoria and Venetian Driers, a Eureka Sifter, and the turbine also drives a circular saw. There is now to be added one of Greig's Witherers erected under this Engineer's personal supervision

Already, Mr. Dickson has provided with the aid of a village carpenter (the work not costing more than 20 rupees) one of Greig's patent roll-breakers—a fan with strong arms, running 400 revolutions a minute into which the rolled tea is shovelled by a boy and sent streaming out in a shower—the contrivance saving the time of 2 coolies a day!—250 lb. of tea is broken up in 4 minutes in this way.

The Lebanon Factory is, as already mentioned, to have electric light, and this is to be provided by a separate turbine of 10 horse-power, so as not to be affected by the slackening or stopping of the machines driven by the larger wheel. The smaller turbine will also be useful in dry weather, or in a season of prolonged drought, to drive the rolling, &c., machinery when possibly there might be a scarcity of water for the bigger turbine.

The flood which occurred on the Knuckles rivers during last south-west monsoon is said by the "oldest inhabitant"—the arachchi of the village—to have been the biggest within his memory and there is this to justify his opinion, namely, that a huge tree used as a bridge over one division of Lebanon stream, which had remained safe since the place was opened in 1858, was carried off this time and made matchwood of at the foot of the estate. Mr. Dickson's wire bridge—one of the longest in the island—was also carried off, and for a week communication destroyed, so that the coolies were in danger of starvation till he contrived a means of sending rice over. Across the river Mr. Dickson had formed a low dam between two enormous rocks (so as to send a full supply into his watercourse); huge blocks of stone were keyed in and formed an arch against the stream, so that the force of the flood could not bend or drive it, but the waters lifted this mass of keyed stone upwards and blocked the opening below with small boulders, gravel, debris, so that now it forms more of a dam than ever!

DR. DUKE'S TEA SCHEME FOR AMERICA.

Planters' Association of Ceylon, Kandy, 18th Oct. 1888.

The Editor,

Sir,—I enclose copy of Dr. Duke's letter submitting his scheme for making Ceylon tea known in America. —Yours faithfully, A. PHILIP, Secy.

Kandy, 24th September 1888.

The Chairman of the Planters' Association of Ceylon:

Sir,—As a member of the Planters' Ass'n of Ceylon, and one personally interested in the staple industry of the island, I beg to submit the following comparatively economical scheme for making known the merits of Ceylon tea throughout the United States of America, and I shall be obliged if you will kindly lay it before your Tea Fund Sub-Committee for consideration, and if approved to act upon it and work out the necessary details.

The following is the scheme which I would suggest, viz:—

1. To utilize the 6,000 lb. tea not now required for Mr. Elwood May by dividing it into 1,200 packets of 5 lb. each, each to be packed into neatly made boxes, and each box to contain a short pamphlet showing the development of the tea enterprise in Ceylon and also giving instructions for the proper infusion of the tea leaf, &c., &c.

2. These boxes to be shipped direct to New York, or any other American port to an approved agent, and by him to be distributed by parcel post as a Christmas present from the Planters' Association of Ceylon to the editors of 1,200 of the leading daily newspapers, including the medical journals and those organs advocating total abstinence throughout the United States, Canada, and California. The advantages that would result from this procedure would, I anticipate, in the

first place be a very extensive publicity not to be obtained by any ordinary means of advertising within our reach, as the gift would probably elicit favourable editorial comment and in many instances no doubt a transcript or extract from the pamphlet would find its way into the columns of the papers as the article is one of such general interest.

In addition to this we secure by the consumption of this quantity in the editor's family a fair trial of Ceylon Tea by 1,200 men of more than ordinary intelligence, who to a great extent guide the public taste, and who, from the nature of their profession and its powerful influence, command a very large circle of acquaintances and friends.—I am, &c.,

(Signed) VALENTINE DUKE.

THE COCA PLANT IN CEYLON.

Messrs. J. P. William & Bros. of Henaratgoda write:—"We send you by this post two branches of *Erythrocylon Coca* pale leaved variety, and *E. Coca* dark leaved variety. We imported parent plants of the pale leaved variety; it grows fast and yields plenty leaves and produces a small quantity of seeds; the dark-leaved variety which exists in Ceylon produces large quantities of seeds and small quantity of leaves, grows slowly; the pale variety is the true and best kind in commerce and fetches a high price. We have a tree of the pale variety two years old 4 feet high and $3\frac{1}{2}$ feet circumference * loaded with a large quantity of leaves, and the dark variety of same age $1\frac{1}{2}$ to 2 feet high with a small quantity of leaves and a large quantity of seeds."

TEA SEED.—With reference to a recent warning a planter writes:—"Seed which has been plucked before it is *properly ripe* ferments and rots soon after packing, but ripe seed will retain its vitality for a considerable time. The kernel of a ripe seed has a rough skin adhering to it; immature seed has none, but some of the Calcutta experts don't seem to recognise this fact, and pass all seed as *good* which is not absolutely rotten at the time of inspection."

CEYLON TEA AND ITS KEEPING QUALITIES.—We call special attention to the letter of "M." on this subject on page 351: it deserves the serious attention of every planter and merchant interested in the future of Ceylon tea, for, as the writer remarks in a private note:—

"I fear we shall wake up in a few months' time to the fact that we might have attended to our tea manufacture as regards its 'keeping quality' with very serious advantage to ourselves."

Our correspondent makes certain practical suggestions which, we trust, will receive the prompt consideration of the Planters' Association Committee, backed as they are by a clear offer of practical help in any special attempt to solve the present difficulty.

SELLING CEYLON TEA IN THE UNITED KINGDOM is declared by recent arrivals in the island to be an exceedingly profitable business for not a few ex-Ceylon colonists engaged in it. Among others, Messrs. Roger and Bett of the Glasgow Planters' Agency are named as already doing a very large and rapidly expanding as well as profitable business; while "J. A. Robertson" of Dinubula fame is said to be carrying all Yorkshire before him with his numerous shops for the sale of Ceylon teas. The figures given for the weekly sales in some of these cases stagger us, for they exceed by a good deal those appertaining to London-Ceylon tea agencies for the *monthly* sales, even though for one of these agencies, three Baronets were actively interested if not engaged in making the merits of the teas known. We suspect the Yorkshire and Glasgow figures want a little amendment.

* Branches round the tree,

CHINA TEAS.—A Ceylon planter now at home sends us the following extract from a home paper:—"The rapid decline of our trade in tea with China, owing to the increasing hold which the teas of India and Ceylon are obtaining on this country, has at length begun to arouse the attention of the Chinese growers and shippers. The exports from China to London up to the 11th of August of this year are stated to have been 59,000,000 lb. as against 94,000,000 lb. in the corresponding period of four years ago. This heavy falling off is mainly attributable to the export duties levied on tea leaving China, whilst the rival teas of India and Ceylon are free of such imposts. A Trade Committee of Inquiry acting with the Shanghai and Foo-Chow Chambers of Commerce has recently expressed an opinion 'that the only real remedy for preventing the total extinction of the trade is the abolition of all export duties, so that the China article may be on the same footing with the Indian, Ceylon, and Java, all of which are now free from tax.' The quality of some of the recent arrivals of black leaf teas of congou and souchong descriptions has been very poor and fetched very low prices."

BULLING QUININE.—A letter appeared in a financial contemporary on the position of this quinine, in which investors are tempted by brilliant representations of the money to be made in the article. The reasons advanced by the anonymous correspondent are not likely to influence people posted in the past history of quinine; but it would be a pity if it had the effect of "landing" any of the numerous class of investors who run after supposed good things even though they know next to nothing about them. The Ceylon estimates of cultivated bark area and future exports, upon which the writer largely bases his arguments, have more than once proved unreliable; and as a matter of fact the compilers of these returns themselves acknowledge, in the Ceylon papers to hand by this week's mail, that they have wrongly estimated the very number of growing trees upon which the letter-writer bases his calculations. Similar innocent-looking attempts at bulling the market were made last autumn, and paraded with much show of satisfaction by speculators.—*Chemist and Druggist*, September 29th.

TEAS AND TEAS!—Already we learn there are anticipations abroad of a poor time coming for Ceylon teas. We cannot see it ourselves just yet, with Indian exports below the estimate so much, the China returns showing no sign of recuperation, and our own deficiency on estimates. But already dealers are scenting afar off the time when "Ceylons" are to be poor again, due to "newly pruned teas." Surely it is too early to begin this cry, and in view of so many plantations now doing their pruning by instalments all the year round, save in the very dry months, it will be rather difficult to distinguish the period for poor teas and depressed prices. In this connection, we cannot help recording the experience of a Rakwana proprietor, who, for some time, was conscientious enough to place "N. P." ("newly pruned") on the boxes containing his first teas after pruning, with the result, as soon as the mystic letters were explained in the Lane, of considerably less prices. Latterly, however, he has given up this practice, and he says his "newly pruned teas" now fetch quite as much as any others from his property. Once again, a Dimbula proprietor making up a sample package of a break of tea, per post, found three packets (a triangular affair) rather awkward for the tappal, and so added a fourth, taking the tea from the same bulk as one of the others, but forgetting so to label this 4th package. He had a very good report from the Lane on his three marked samples, but the 4th (unmarked but really a duplicate) package was condemned as burnt and inferior!

TEA IN BURMAH.—The *Mandalay Herald* trusts the general success that has attended tea culture in Upper Burma will attract those who have been forestalled in Assam, India, and Ceylon. "We have the climate, soil, and temperature, and millions of acres in Upper Burma that are offering themselves to the planter, if he will only go to them and use them. All that is required, is that authoritative publicity should be given to what the local Government has to offer to planters and others."

CHEAP SULPHATE OF QUININE.—A few months ago we published details of a process adopted by Mr. Gammie of the Government cinchona gardens in Sikkim for making sulphate of quinine cheaply, by means of caustic soda and fusel and kerosene oils. At our request, Mr. Gammie sent us a box containing the various ingredients required, and we handed them to Mr. Cochran, who has kindly made some sulphate by this process, which is a somewhat troublesome one in the absence of the apparatus used for shaking the materials up. The specimen before us took a boy five hours to shake up! It is a very nice looking sample, and we do not see why a regular manufactory should not be started in Colombo, for supplying the local market at any rate. The specimen referred to can be seen at this office.

COFFEE.—We are now asked to give up coffee. A writer in *The North American Review* dogmatically asserts that it produces blindness and all sorts of mischief besides, and turns a growing lad into a "runt"—whatever that may be. He declares that what he says is based on his own experience. He had good eyes, and needed them for his trade; but his sight was nearly ruined by copious coffee. "A horror of darkness" set in, and he longed to get to some place where there were short nights—or, as we should say, long days—all the year round. But many people who were not intemperate coffee-drinkers have been known to express the same wish. The writer warms to his subject as he gets on, till in time we learn that "Coffee-drinking exhausts the mouth and throat, leaving the face a grinning skeleton, while the body is honeycombed." This beats anything we have heard of whiskey! She will be a brave woman who sips the aromatic herb in the teeth of this "grinning skeleton." Perhaps, however, the writer did not take his coffee "neat." The worst of it is, he has not told us what we are to drink.—*Christian World*, Sept. 20th.

AN "ARBOR DAY" FOR CEYLON.—"With a view to remedying the waste caused by the reckless cutting-down of trees, a voluntary tree-planting movement was begun in the State of Nebraska about fifteen years ago. One day in every year was set apart for the business, and called 'Arbor Day,' and that day local authorities, notabilities, and people in general celebrate by planting trees. The example has been followed by several other of the Western States, with the result that a considerable territory has been reafforested. The success which has attended 'Arbor Day' in America makes one wonder whether, like so many other Transatlantic products, it would bear transplantation to this country." So writes the *London Graphic*; and could not something of the kind be attempted in Ceylon in connection with fruit-trees. Dr. Kilner many years ago advocated a toll on our great North-road in the shape of each traveller being obliged to carry and place in the soil at proper intervals a few palmyra-palm seeds. Had this been begun thirty years ago, the road from the Jaffna Peninsula to Matala might be lined with this hardy and useful palm by this time. Could not the boys of Mission and indeed Government schools be interested in an "arbor" or "fruit-tree" day?

Correspondence.

To the Editor.

HIGH-PRICED TEAS.

Matale, October 7th, 1888.

DEAR SIR,—According to "Rucker & Bencraft," Mr. Gordon Reeves of Hoolankande, had the honor of sending "perhaps the finest invoice of tea ever dispatched from Ceylon." This consisted of 70 packages averaging 1s 10½d, B. O. P. 2s 8½d, P. 2s 17d, P. S. 1s 6½d, dust 1s 0½d.

If you refer to the *Tropical Agriculturist* of October 1885, you will see that much higher averages were obtained by Loolcondura and Blackstone; the former averaging 2s 0½d for 62 packages, B. P. 2s 4½d, P. 2s 2d, P. S. 1s 10½d, broken tea 1s 6½d, and dust 1s 7d, while Blackstone averaged 2s 4d for 32 packages. The B. P. fetching 3s 2d, P. 2s 2½d, and P. S. 1s 7½d. Again vide *T. A.* March 1887. Blackstone for 32 packages averaged 2s 2d, the range of prices being 1s 0½d at 3s 2d,

Now see what Agarsland averaged when Mr. Hall was the superintendent of the place. Agarsland average 2s 1½d, range of prices 1s 0½d to 2s 7½d. *T. A.* June 1887; and again vide *T. A.* April 1887, Agarsland average 2s 7½d, range of price 1s 6d to 2s 7½d and 3s 2½d. The last is, I think, the highest average yet obtained for Ceylon tea, while the highest price for a special tea, was if I am not mistaken, 3s 10d for 2 boxes O. P. or flowery pekoe from Strathellie.

The brokers say that really good teas fetch as high prices now as ever they did before; if this is so, Hoolankande will have to take 4th place, and therefore has not the honor of "perhaps sending the finest invoice of tea ever dispatched from Ceylon."

E. B.

[Has "E. B." observed what the general average for Ceylon teas was at the several dates he refers to? This is an important element in any comparison.

Ed.

COTTON GROWING.

SIR,—Can you or any of your readers inform me how the new product cotton is to be grown, all about the nursery, the depth of the holes, and all concerning it, and also what books will teach me further on the subject?—Yours faithfully,

'SWAN.'

P. S.—Is cabook soil suited for cotton?—S.

[Let the ground be forked over and sown made, 2 seeds dibbled into each hole a few inches deep, and say 3 to 4 feet apart; no need for a nursery. The cotton plant succeeds better in light and sandy soils than in such as are heavy and clayey. Cabook soil would have to be broken up and made friable. Study the *Tropical Agriculturist*.—Ed.]

SILK FROM COCOONS.

Agar's Land, 14th Oct. 1888.

SIR,—I am this day sending you by post two cocoons of two different kinds of silkworms, which I got on this estate. The round cocoon caterpillar I find on the olive or common *weratu* tree, also on the small black *jumbum*, or *dan hindan* fruit tree (a small black fruit often sold in Colombo heap'd in baskets) called *manu palkam* in Tamil. I find these caterpillars on these two trees only. The other caterpillar of the *fatted cocoon*, and which appears to be the best silk by appearance, is found in great quantities on the *endanam* tree or shrubs.

I should feel extremely obliged for any information from silkworm rearsers as to how to act in procuring or extracting silk from these cocoons, and

by what method, and what machines are used? I can supply cocoons (folded ones) on application.

JAMES GRAY.

The one cocoon represents the Tusser silk moth and the other the rather common Atlas moth which our correspondent is wrong in supposing to be the more valuable: the Tusser silk being superior; its usual food is found on the country almond tree. Our *Tropical Agriculturist* volumes give a good deal of information on the subject.—Ed.]

DOES CEYLON TEA KEEP?

Colombo, Oct. 22nd, 1888.

DEAR SIR,—Is not the present time suitable for having this question worked out by some concerted action and set at rest?

Following upon the outcry a few months since, the letters recently written to the *London Standard* and reprinted by you in the *Observer* of the 8th instant, and Messrs. Rucker & Bencraft's circular of Sept. 27th show the necessity (if possible) for improving our teas as regards their keeping qualities.

I have letters from London from people interested in the welfare of Ceylon tea in which they write: "The opinion is gaining ground that Ceylon teas do not keep," and, whether true or not, we may be sure that our India and China competitors are not likely to let the idea drop.

At the moment, as we are getting fair prices and our stock at home represents, say 2½ months' supply, the shoe does not pinch us; but later on when the stocks are trebled and probably reach an average of 6 to 7 months' supply of a largely increased consumption, the keeping power of our tea must make or mar us.

Primarily it appears to me that the Planters' Association should devote attention to the subject, and now that they have funds in hand and incoming more than sufficient to meet the cost of representation at Exhibitions, I suggest that probably the best plan would be to offer substantial prizes for practical essays giving results of tests, say R600 or more for 1st prize and proportionate sums for 2nd and 3rd.

If I am wrong as regards the P. A. funds, I should be willing to contribute to a special fund for these prizes.

If our teas do not keep; in other words, if they go off in about 3 months' time after landing in England or elsewhere, one cannot help thinking whether we are not putting the cart before the horse, in forcing new markets and having our teas ultimately condemned on this ground, before first correcting the faults of our manufacture.

I have for some time thought that in one or two directions we have pushed economical working too far at the expense of efficiency:

- 1st. In duration of final firing by machinery, the remedy possibly being a reversion to "chulas."
- 2nd. In thickness of lead used for packing. The standard in vogue, viz., 5 oz., is thin compared with lead used by the Chinese, but with a tendency to try 4½ oz., 4 oz., and probably thinner sheets, wisdom would suggest careful trials to show the happy medium between safety and economy.

3rd. Is it not the case that in some factories where they pack as they make and sell in the local market, that teas are not final fired at all?—Yours truly,

M.

CEYLON TEA AND THE LONDON DOG.

SIR,—Last month I saw at the London docks a large quantity of tea, the quality of which appeared to me to be of the highest.

My experience during the past few years shows an alarming and almost total loss of tea by insects, mainly small compared to what prices

"in the trade" lose. The merchant has not so direct a cause for complaint as the producer, nor can he assert positively that proper weights of tea have been leaded up in the boxes, unless he re-bulks before putting his packages on board ship in Colombo. I have patiently endured the loss on my teas shipped to London for these past years, thinking probably like many other Ceylon producers, that it was beyond our reach trying to remedy the evil. Recent disclosures, however, of pilfering (if we call it by no harsher term) appear to give us an opportunity for "grasping the nettle." I feel sure if the subject is taken up and properly handled by the Planters' Association and Chamber of Commerce, aided by London merchants interested in the tea trade, a cleansing from all such untidiness as "two waggon loads of samples," or a trifling matter of two to four per cent loss in weight on tea to Ceylon growers would be effected. "Two to four per cent" appears to be a very large order, yet, so I have worked it out, over a series of tea sales in London, and I have no doubt but many a Ceylon planter will find a similar sad experience if he turns over his London invoices. From information recently received, blame for loss in weight of Ceylon tea in London appears to be thrown upon the producer; the arguments used are that Government supervises the weighing of our teas in the London docks, and that the weights mentioned on the invoice could never have been put into the packages. This is no doubt a strong disclaimer, yet we have these "two waggon loads" of odds and ends to create suspicion; and moreover we need further information on many points. Is the sampling done prior to this Government supervision of the weighing? Is it not possible for Government supervisors to be in collusion with samplers *ad hoc*? Is it likely that breaks of tea from the same factory weighed carefully and packed under European supervision would vary in loss of weight to the following extent:— $1\frac{1}{2}$ per cent, $2\frac{1}{2}$ per cent, 4 per cent, $2\frac{1}{2}$ per cent, 3 1-16th per cent, and 3 per cent for years past, unless *unreasonable* quantities were extracted for sampling purposes? Is it not the usual practice for Ceylon growers to put in each chest, or $\frac{1}{2}$ chest $\frac{1}{2}$ to $\frac{1}{4}$ lb. extra of tea, so as to make up for any samples which are taken?

An ordinary garden would ship say 30,000 to 40,000 lb. of tea per annum: it is therefore a serious matter for a proprietor to face a loss of even 2 per cent, which would represent 600 to 800 lb. of tea in the year, without considering the $\frac{1}{2}$ at $\frac{1}{4}$ lb. given gratis to the samplers.—I am, &c.,

SHELTON AGAR.

FRESH SUPPLIES OF CUPREA BARK READY FOR HARVESTING.—In the unlikely case that our bark supply from other quarters of the world should fail, or if prices should again become sufficiently remunerative, we may expect (if a German authority is to be relied upon) a renewed influx of large quantities of Cuprea bark. It has hitherto been generally believed that the reckless destruction of the Cuprea forests between 1879 and 1884 had practically exhausted these sources of supply, but we now hear that while the forests in the Lebrija and Sogamossa valleys of the Republic of Colombia were actually destroyed, other woods have escaped; and that, moreover, fresh trees have by this time grown up from the roots of the trees felled seven or eight years ago. The Cuprea roots, unlike those of the Colombian *C. Lancifolia*, are valueless for manufacturing purposes, and thus, while the *C. Lancifolia* trees have been hopelessly exterminated, the second generation of Cuprea is now again ready for the axe.—*Chemist and Druggist*, September 29th.

COTTON GROWING IN THE GAMPOLA DISTRICT.—Mr. Blackett's clearing of cotton now shows bushes approximating to a foot above the ground, certainly an average of 8 inches in height in six weeks from date of dibbling in the seed. The bushes look healthy and promising.

HOOLANKANDE ESTATE (Mr. Gordon Reeves) has the honour—according to Messrs. Rucker & Bencraft—of sending to the London market "perhaps the finest invoice of tea ever despatched from Ceylon." This consisted of 70 packages, averaging 1s 10 $\frac{1}{2}$ d (pekoe souchong 1s 6 $\frac{1}{2}$ d; broken orange pekoe 2s 8 $\frac{1}{2}$ d; pekoe 2s 1 $\frac{1}{2}$ d; dust 1s 0 $\frac{1}{2}$ d). This shows what fine picking (under 100 lb. per acre) and careful preparation of a high-grown tea can do. Messrs. Gow, Wilson & Stanton give the average at 1s 11 $\frac{1}{2}$ d.

SILK (writes a Coventry ribbon manufacturer) has been very cheap for some years. If Ceylon can grow silk to a profit now, it need never be afraid; for, unless through panic, as in a revolution, it is not likely to go lower in price. Enclosed is a small pamphlet on the subject and if any further information is required, I feel sure that Mr. Wardle of Leek, Staffordshire, would gladly give it. It is his special study. He has compiled a work on "Silk. Its Entomology, History and Manufacture."

THE SPECIMEN OF QUININE manufactured by the new process on the Government Cinchona estates submitted to Government for approval, is said to be as good as Howards. Steps will be taken to test its pharmaceutical strength as soon as a sufficient quantity is available for distribution. It is premature to form an opinion merely on an experiment, as between the manufacture of a specimen and quinine in bulk, there is a great gulf fixed. We have no doubt our practical Director and Quinologist will be able to produce quinine as good as that obtainable at Darjeeling.—*South of India Observer*, Sept. 25th.

"NEW DISEASES."—Those words (says Dr. Taylor of *Science Gossip*) are ominous. The too-well-known potato disease was unknown till about the year 1846. The vine diseases are equally modern. Coffee-planting has been ruined in Ceylon since 1872 by the fungus. Are we developing new diseases? It looks like it. The latest news is of another and hitherto-unknown species of potato disease which, under the name of "scurl," is attacking the potato-crops in Germany. Dr. Thumen also describes a new species of vine disease in South Tyrol, which is destroying the immature berries, and which is due to a hitherto undescribed species of microscopic fungus.

FIBRE.—Scientific enquiry or often times chance bring to light resources unthought of in the vegetable world. Mons. J. de Turck, Lille, is using in his mills a quantity of what he calls "lin exotique." It is the product of the dolichos of Tonquin—the dolichos catjang of Cochin China—known through Tonquin as dau, one of the chief food crops of the country. The fibre, which resembles ramie, is, when decorticated, long and lustrous, and while possessing great strength can be used in the manufacture of the finest lace or strong cord. It is spun without combing, a great saving as compared with common flax, and it can be worked up with flax, cotton, or wool. The cost at Marseilles is from 10 to 20 cents per kilogramme (2 $\frac{1}{2}$ lb.) This plant, which is much cultivated as a clearing crop, is grown from seed sown in February or March, and ripens about a month before the rice crop. The pods are gathered in baskets by women and children, the stalks being mostly ploughed in or used as bedding for the buffaloes. Apart from the food-producing quality of the plant the economic value of the stalk would recommend its cultivation, and it would probably suit warm valleys in Natal.—*Natal Mercury*.

IMPURE AIR AND DAIRY COWS.

On a certain farm twelve cows were in the habit of passing the putrefying carcase of a calf, at a distance of about 100 yards, each time they went to be milked. They breathed the stench-laden air for a minute only each time, but this was sufficient to spoil both their own milk and also that of the remainder of the herd of eighty cows. In another case, the scent of a bed of onions was sufficient to give an objectionable flavour to the milk that the cows yielded immediately afterwards. These facts are sufficient to show the importance of providing pure air for our cattle, if our dairy products are to be of high quality. Nothing in the nature of an offensive smell should be allowed to exist either near the dairy or near the animals themselves. You can't get good milk unless the cows get plenty of clean, fresh water to drink whenever they want it.—*Farm and Home.*

[What about cows kept by natives in Ceylon for the supply of milk and butter? Is any attention paid to pure water and uncontaminated air?—Ed.]

PAPER PULP FROM COTTON STALKS.

For several weeks says the *Atlanta Constitution*, there have been on exhibition in the office of the clerk of the Superior Court samples of pulp made of the hulls and stalks of the cotton plant. The pulp is as white as snow and can be converted into the finest writing paper. It is regarded as valuable, and is the product of parts of the cotton plant hitherto deemed valueless.

The process by which it is made is new. It is a process by which the ligneous substances of the hulls and seed are dissolved. By this process over fifty per cent of the fibre is extracted from the hulls which have been regarded as fit only for fuel in the mills or for feed and fertilizing purposes, and which were sold for four dollars a ton. These converted into pulp will be worth about forty dollars a ton. From the stalks usually left to rot in the fields this new process utilizes about thirty-eight per cent of fibre at a very small expense. It has been settled that there are fertilizing properties in the oil of the cotton seed and it is asserted that the fibre will not decompose for six years and cannot be used as a fertilizer. This is why the woody matter eliminated from the stalk and hull is much more valuable as a decomposing fertilizer than the entire seed. By the same process the ramie plant and its troublesome cousin, the bagasse stalk is met and overcome. By the deoercenting process the fibre was crushed and torn out by a slow and expensive process.

In the new process the lignite is simply dissolved out, and the snowy fibres of the ramie and the tawny threads of the sugar cane are coaxed out as easily as the infantile kitten to its milk.—*Indian Agriculturist.* [Which we suspect is too good to be true.—Ed.]

IMPROVED PADDY CULTIVATION.

CULTIVATION OF PADDY AT TOPPUR.

Report of crops obtained by the Agricultural Instructor.
 (1) By "planting out" the paddy, after ploughing with the improved plough, the Agricultural Instructor obtained 99 bushels of paddy from 20 measures seed planted out on 2½ acres, or a nearly 100 fold, or 18 bushels crop per acre, or to only 8 bushels seed per acre, the usual amount of seed paddy used in that neighbourhood being 3 bushels per acre.

There was thus a saving of seed of 2 bushels and 24 measures per acre, while the average crop of the neighbours who cultivated in the native way was 21 to 24 bushels per acre, or 1 fold only.

(2) By omitting "planting out," and still using the improved plough, he obtained 90 bushels per acre from 1 bushel and 18 measures sowed broadcast per

acre, a yield of 22 fold, against the native 21 to 24 bushels crop per acre from 3 bushels sowed per acre broadcast, on the native system.

No manure was used, and except for the use of the plough, and "planting out," the Instructor cultivated under exactly similar conditions to his neighbours. This is the second successful crop raised by the Instructor from the same fields, it having been objected in some quarters to his former success that our system might be all very well for one crop, but that it would not last.

Reports by the Villagers who Cultivated on the New System.

No. 1.

7th September 1888.

M. L. Capepu Mohamet, headman of Toppur, begs to report that he ploughed this year about ½ acre of land with the improved plough, and, according to the instructions of the Agricultural Instructor, he sowed about 3½ measures of paddy in it. The quantity of the crop realized in it was 23 bushels. Thus the quantity realized in the part cultivated with the improved plough was much more than that of the other parts.

No. 2

10th September 1888.

V. V. Sagurthamby begs to report that he ploughed this year ¼ acre of land, which never produced a good crop before, trampled it, and sowed in it about 10 measures of paddy. The plants in this part grew much better than those in other parts. The quantity of the crop realized in it was 8½ bushels and 3 measures.

No. 3.

10th September 1888.

T. Katharsaibu of Toppur begs to report that his younger brother desired to cultivate a portion of his field according to the new method of cultivation. So Katharsaibu and his brother ploughed about ¼ acre with the improved plough, and after having trampled and levelled the ground, sowed paddy in it. The quantity sown was ½ bushel and that realized was 12 bushels. The quantity realized in this part was twice as much as that obtained in those parts prepared without ploughing.

No. 4.

11th September 1888.

S. L. Agamadu Lebbe begs to report that the cultivated about ¼ acre with the improved plough, and according to the instructions given by the Agricultural Instructor, sowed in it about 8 measures of paddy. The quantity realized in it was 7½ bushels. Thus of all the plots he cultivated, this one (¼ acre) produced the largest quantity.

No. 5.

13th September 1888.

Aliar Tamby Moideen Baba of Toppur begs to report that he cultivated ½ acre of land this year with the improved plough, and according to the methods adopted by the Agricultural Instructor, sowed in it germinated paddy.

The quantity of seed paddy was ½ bushel, and the quantity realized in it 10 bushels and 5 measures.

Of all the pieces of land he cultivated, this ½ acre produced the largest quantity of crop.

No. 6.

15th September 1888.

K. M. Sinna Markar of Toppur begs to report that, in Kiranvely, he cultivated ½ acre with the improved plough, and, after having trampled it, sowed 1 bushel and 2 measures. The quantity realized in it was about 19 bushels. Thus this ½ acre produced a better crop than the other pieces of land cultivated by him.

No. 7.

20th September 1888.

M. L. Kappaththay of Toppur begs to report that he ploughed about ½ acre of land with the improved plough this year, and after having trampled it, sowed in it 2 measures of paddy. The quantity realized in it was 10 bushels and 21 measures. The paddy plants in the part cultivated with the improved plough looked better than the plants in other parts.

He also planted out a small portion of his field, and removed the weeds according to the method adopted by the Agricultural Instructor.

This piece of land also produced a larger quantity of crop than any other part.

POISONS AND ANTIDOTES.

The following list of simple anti lotes to the common forms of poison will be found useful to servants who get hold of the wrong bottle:—

POISONS.	ANTIDOTES.
1. Acid—Carbolic, sulphuric, nitric, muriatic, nitro-muriatic, creosote, iodine, phosphorous.	White of egg well beaten up with water. A teaspoonful of mustard flour in a cup of hot water. Very thick lime water—(in case of sulphuric, nitric, muriatic, or nitro-muriatic acids).
2. Chromic acid, chromates, all preparations or compounds of chromium, antimony, copper, mercury or zinc.	Abundance of white of egg in water. A teaspoonful of mustard flour in water. Copious draughts of an infusion of salt herbs.
3. Ammonia, soda, potash, alkaline, silicates, and sulphates.	Strong vinegar and water. Large doses of oil. Large doses of milk.
4. Prussic acid and its salts, all cyanides and sulpho-cyanides, oil of bitter almonds, and nitrobenzene.	Continuous and heavy cold water over the head and spinal column. Mustard plasters on the stomach and soles of the feet. Prevent sleep.
5. Ether, petroleum, benzine fruit essence, concentrated or absolute alcohol.	Plenty of mustard flour in a large quantity of hot water. Cold water douches. Fresh air. Prevent sleep absolutely.
6. Compounds of baryta and lead.	A teaspoonful of mustard flour in warm water. Strong solutions of Epsom salts and Glauber's salts in cold water.
7. Compounds of arsenic.	A teaspoonful of mustard flour in warm water. A teaspoonful of dialysed iron mixed with the same quantity of calcined magnesia every five minutes for one hour. Then plenty of oil, or milk, or some mucilaginous tea—say linseed.
8. Oxalic acid and its salts.	Very thick paste of lime and water by large spoonfuls at the time. After several of these, large draughts of lime water. Finally, 4 ounces of castor-oil.
Nitrate of silver.	Large doses of ordinary kitchen salt dissolved in water, after which one teaspoonful of mustard flour in warm water.
10. Nitrous fumes of vapours, arising in vitriol or chemical works.	Frequent and small doses of strong acetic acid—the stronger the better.

—Indian Tea Gazette.

TEA WEIGHTS.

I have been assisted most materially by the Managing proprietor of one of the principal Bonded Warehouses, who has kindly given me a good deal of valuable information. I cannot do better than give two examples, first, how teas ought not to be packed; secondly, how they ought to be packed, so as to secure a minimum of loss. I can best illustrate my remarks by the following small tables which, however, apply to

the weighing of teas that are not bulked in Ceylon, or, if bulked, so badly done that they have to be re-bulked in London:—

TABLE I.
How teas ought not to be packed.

Actual gross weight of each package in Ceylon including all iron, hoops, nails, &c.	Customs' gross weight in London.	Actual tare or weight of each empty package in Ceylon.		Customs' tare in London.		Actual nett weight in Ceylon.		Customs' nett weight in London.	
		lb.	oz.	lb.	oz.	lb.	oz.	lb.	oz.
139	15	139	40	1	41	99	14	93	

TABLE II.
How teas ought to be packed.

as above as above								
lb.	oz.	lb.	oz.	lb.	oz.	lb.	oz.	
140	2	140	39	14	40	106	4	100

In table No. I, it will be seen that the importer loses 15 oz. on both the gross and the tare, 1 lb. 14 oz. per package, and, though this may be termed an extreme case, it does frequently happen. In table No. II., the loss it will be observed, is only $\frac{1}{4}$ lb. per package. Should, for example, a package be found to tare (which tare must be ascertained before packing), 39 lb. 13 oz., then 100 lb. 5 oz. must be packed in order still to make the gross 140 lb. 2 oz., tare 40 lb. = 100 lb. nett. But in the event of packages taring, say 39 lb. 12 oz., 11 oz. or 10 oz., these packages must be increased in weight by adding more wood to the empty packages, so as to bring them up to the requisite standard, namely, 39 lb. 13 oz. or 14 oz. Although 39 lb. 13 oz. or 14 oz. is given as an example, it is immaterial that all the packages should run the same, the great principal is that the tare of all should be 2 oz. to 3 oz. under a pound.

Teas, if properly bulked, are always weighed nett: that is, the contents of 10 per cent. of each grade are weighed in bags, and the average nett weight represents the parcel. Care should be taken by packers in Ceylon that the nett weights run as evenly as possible. 3 oz. should be allowed as overweight in each package. —A. M. GEPPE.—Local "Times."

PEPPER CULTIVATION.

In the last issue of the "Tropical Agriculturist" was published an excellent article on the cultivation of pepper. But, there are some practical difficulties in adopting the system advocated by "a planter." The first and foremost of them being the selection of posts for the support of the vine. Permanent posts of timber as advocated by "a planter" will not serve in Ceylon where the attacks of white ants are too notorious to be dealt with in this article. Besides, the expenses of "splitting of permanent posts" will be something enormous. I give below the system of cultivation adopted in Malabar which is pre-eminently the pepper producing country in the world.

There are two systems prevalent in Malabar, the one, by the ordinary cultivator who owns a small area of ground, and the other, by "gentlemen farmers" who own extensive grounds, and who can command a capital.

To begin with the first:—a red gravelly soil capable of retaining moisture, with a goodly number of mango and jack trees growing on it, is preferred. The mango tree is reckoned the best for the purpose. A mango tree ought to be at least twenty years old before any pepper vines are put on it; for it is believed that a younger tree will produce less fruit when there is vine on it than it would otherwise do. At the commencement of the rainy season, which is the South West monsoon in Malabar, the soil round the tree is dug, and a small bank, at a cubit distance from the root is formed to confine water. Then from 8 to 12 shoots of the vine, according to the size of the tree, are laid down within the bank with three inches of the vine slanting up against the tree. The shoots are about a cubit long. They are then covered

with fine mould and earth. As the vines grow they must be tied up to the tree. In the hot season they require watering. At the commencement of the next rainy season, leaves, ashes, dung, &c., must be put near their roots and fresh earth thrown up. The pepper vine begins to bear at five years of age. In four years more it is in full bearing. An ordinary tree will produce 20 lb of pepper, and a good one as much as 30 lb.

The second method, *i. e.*, of opening large plantations, is as follows:—A hill-side with an eastern aspect and gentle slope is selected. The land is cleared of its jungle about April, and burnt. The ground is then hoed, and steep slopes are converted into terraces which is very essential to keep the surface soil from being washed off by rain. After a few freshes, just before the regular monsoon begins, hill-ricc, dholl, and coft are sown broad cast. About the middle of June, set in plantain trees at a distance of 8 feet apart, and plant Erythrina branches at a distance of about 15 ft. apart, or, say at the rate of 200 trees to an acre. Sometimes 300 trees are also planted, but it is believed that pepper vines would not bear well when planted close together. The Erythrina branches should be from 6 to 12 ft. long. During summer these trees must be watered, if they have not taken sufficient hold in the soil to take care of themselves. When the monsoon has fully set in, preparations should commence for regular planting of the vine. There are two ways adopted by the planters. Some people take 6 or 7 cuttings, each a cubit in length, and put them in a basket with their upper end sloping towards the tree. The basket is then filled with earth, and buried in the ground at the foot of the tree. Between the middle of October and the beginning of November the earth round the basket is dug; and, as a manure, dry leaves, grass, and cow-dung are put round the vines. Some people plant the cuttings without any basket. It has been found by experience that the "basket-system" prevents many accidents to which the young shoots are liable. Between October and November the vines must be manured, and tied up to the tree until they are six feet high, after which they are able to support themselves. After the third year the plantations are dug up; and twice a year, at the beginning of the S. W. and N. E. monsoon the whole plantations must be hoed, and dried leaves and grasses put as manure. In four or five years the vines begin to bear pepper. In the sixth year they yield a full crop, and continue to do so for 15 or 20 years, when the Erythrina dies, and must be replaced by a new branch and new vines. The pepper vine is liable to be killed by droughts, especially when the N. E. monsoon fails. Attacks by ants and insects are seldom heard of in Malabar, between May and June the vines flower, and by January the fruit is fit for gathering. There is only one harvest in Malabar. The men who collect the crop, go up by ladders, and with their fingers twist off the berries. The fruit is collected in baskets, and after placing them on the ground, rubbed with the feet to separate the berries. Pepper is dried on mats, or, on a piece of ground purposely made smooth by washing, with cow-dung and clay. For three days they are spread out to the sun, but every night are gathered and taken into the house. It is believed that the drying on mats is by far the best manner. A man can daily pick, according to the abundance of the crops from 20 to 30 lb. The rubbing and drying is generally performed by women and children. It is estimated that the expenses of harvest cutting, &c., amount probably exceed one-twelfth of the value of pepper. The vines, on an Erythrina tree, 6 to 8 years old, will yield from 5 to 10 lb of pepper. Attempts have been made, with complete success, to grow vines against every tree found growing in forests where a moist soil is met with.—MALABARIST. ("Ceylon Independent.")

ENSILAGE IN INDIA.

The following is important in showing that good silage can be made of mana grass.—Ed. T. J.

Mr. S. William Hockins writes from Vayitri, Wynaad:—

It is difficult to give a reason for your correspondent's failure with his silo, as he gives no detail as to how or when it was made. Very probably it was made of too old or too dry grass. Silage must be soft and full of juice, with a pungent colour, sweet or sour for cattle to take to it, and must therefore be made of succulent grass. It is, I believe, possible to make silage of the common bracken fern; and land, which was formerly considered useless in the Highlands of Scotland, is now being taken up for silage farms. This sort of silage can, however, only be made of quite young and tender fern, and much that was made at first was uncatable because the fern was old and tough when cut. Similarly old Mana grass or old spear grass could not be made into silage, the first being nearly all flower stalks which dry into uncatable sticks and the second containing 75 per cent. of silica, besides being very tough with sharp edges. Cattle will, however, eat both spear and Mana grass within one or two months of the young shoots appearing after a burn, and will soon kill these if graziers are allowed to graze them daily from April or May when the first throw up young shoots. I should be sorry to try the experiment of feeding cattle on silage made exclusively of spear grass, for though they would no doubt eat it if made only of young shoots, they would probably get little nourishment from it. Young Mana grass shoots will make very good ensilage. I made some last October from young shoots about 18 inches long, which was so sweet and good that we could not fill the feeding troughs quickly enough as the cattle emptied them so rapidly. Ensilage made in the monsoon from Mana grass three to four feet long, without flower stalks, turned out sour ensilage, but the cattle ate it readily—in fact, as long as there was a strong smell of fermentation it seemed attractive to them though very offensive to human beings.

Much better ensilage can, however, be made of smaller grass called by the Canarese, Marawally Hullu, which on good grass land generally grows up with the common Mana grass, and where that has been killed by grazing, takes its place. This grass attains a height of from 2 to 3 feet, does not grow up so soon as Mana grass, which ought to be cut first in June or July when labour is usually scarce, and if it will stand grazing could be grazed till August, then allowed to grow up and cut in October or November. It has an ear like a small barley, and the leaves are on the flower stalks. Ensilage cannot be made of this or any grass unless it is green and succulent when cut. I cut some Marawally grass last year in December to January, which had been grazed till August, but it got so dry from the land wind and sun before I could get it cut that it made poor ensilage, and though I made the rest into hay, which the cattle ate to save themselves from dying, they did not seem to be able to eat enough, and got decidedly poorly. When once the land wind begins, even growing grass withers so quickly, that it is little good for either hay or ensilage, and I think it is very likely this may be the cause of your correspondent's failure. A neighbour of mine made first rate ensilage from Mana and Marawally grass in September to October last year, but the grass land from which these were cut was well covered with trees, and all the flower stalks were picked out before the grass was put into the pit. This was sweet, and greedily eaten by the cattle. Another neighbour has established guinea grass on all worn-out patches of coffee on his estate, and when I saw the grass in August last year it was from 5 to 6 ft. high. The better the grass from which the ensilage is made the better, of course, is the resulting fodder, but I am satisfied that from either Mana grass cut young, say 3 cuts a year at intervals of 2 months from June or July, or Marawally Hullu, quite good enough ensilage can be made to save cattle from starvation in the hot weather. I stall-fed 40 head of cattle from November to April last year,—a period of six months,—and lost very few, though I picked out all the smallest and sickiest cattle on the estate for the experiment. In fact, I lost none because the small Mysore frontier cattle were

giving evident signs, that they could no longer travel long distances over steep grass hills to get a living. From February to April I stall-fed 225 head and the loss was only 15 head, including deaths from old age and accidents (5 head) from October 1887 to July 1888, while in previous years I have lost 30 to 40 out of 160 head, and this is in spite of much of my ensilage and hay being of very poor quality from want of experience in making it and 70 of my cattle being newly purchased in November to January, and therefore unacclimated. The cattle fell off in condition, and I am not yet satisfied that the common grasses will give good enough ensilage to keep cattle in condition all the year round, but I am certain such ensilage will keep them alive for three months of the hot weather when they usually suffer most.

Cattle have been stall-fed on guinea grass ensilage in the hot weather, and 1 lb. coconut ponnac a head a day for some years on the Naliampatties, and are always "fit for the butcher." The following hints as to filling silts may be of use:—

Cut the sides of the pit perpendicular.

See that there is no subsoil flow of water into the pit.

Put a roof over it if it is to be filled or emptied in wet weather.

The pit should not be more than 8 to 10 feet deep or more than 12 feet wide, as it is difficult to make a strong *cutcha* roof more than 15 feet wide—A pit of this size and 27 feet long will take the grass from 20 acres when the shoots are about 2 feet long.

Put the grass in the pit the day it is cut.

If possible only put a depth of 2 to 3 feet into the pit on any one day, and fill on alternate days only. This is to let it settle and ferment, whereby more and sweeter ensilage can be got into the pit.

See the grass cannot catch on the sides of the pit as if it sinks or fall below any point, where it catches, will turn black or mouldy.

Put a *tatty* and a depth of 2 or 3 feet of earth on the top.

If "Silo" cuts his grass young and tender, or at any rate green and succulent, and observes the above simple rules he cannot fail to make good sour ensilage in wet and sweet ensilage in dry weather. If after all his cattle will not eat it as I have heard of their refusing the best Luerne ensilage let him try watering the ensilage continually in the feeding troughs with brine or jaggery water. All the latest ideas on ensilage can be obtained from "Silos for British Fodder Crops," published at the office of the *Field*, 346 Strand, London.—*Indian Agriculturist*.

PADDY CULTIVATION IN MADRAS.

[The extracts which follow have an intimate bearing on rice cultivation in Ceylon.—Ed.—T. A.]

In preparing the soil for paddy the practice in some parts of the Presidency is to work the soil in the dry state and to defer flooding until the tillage operations are finished. But the more common practice is to flood the land at once and work the soil while under water into a liquid mud. The object of this puddling process is "to make the land hold water," and this result is undoubtedly secured but at the expense of the healthy action of the soil.

The crop is both sown and transplanted. When the soil is prepared in the dry state, it is usual to sow; when the wet process is followed, both sowing and transplanting are adopted. The seed for sowing on wet land is frequently sprouted previously; this prevents the seed sinking too deeply into the liquid mud. On the dry prepared soil the seed is sown both broadcast and in lines, the quantity used varying from 20 to 150 pounds per acre. There can be no doubt but that there is in South India a very large waste of seed, from the thick sowing. The annual loss from this cause cannot amount to less than 20 per cent. on the assessment of the land.

When it is intended to transplant instead of sowing, the young seedlings are usually raised in nursery beds, though not unfrequently the seedlings used are thinning pulled out roughly from a broadcast crop growing near. Such plants, however, are frequently dam-

aged and never give such good results as plants that have been reared in a nursery bed. The seedlings vary from 15 to 28 days old; when planted out those about 21 days old are usually best. They are planted singly and in bunches of 2 or 3, at distances of about 6 to 9 inches, either irregularly over the land or in lines. There is, of course, in favour of transplanting a saving of water, from the shorter time the crop is growing in the field, and a saving in the quantity of seed used, though the expense of planting is greater than that of sowing.

Manure is seldom used on paddy land. In some rare instances sheep folding is practised during the dry season, and sometimes a leguminous crop is grown on the land and ploughed in as a green manure. Leaves of trees are also used as green manure, but generally the manure given to paddy-land consists chiefly of rain-washed village ashes. Most irrigated land has to depend entirely on the silt brought in the irrigation water. In some cases the water brings large quantities of fertilizing silt, but not unfrequently the water is either entirely without any suspended silt, or the silt consists only of finely divided sand, having no manurial value.

After the crop has been sown, or planted, the irrigation floodings are commenced. The practice differs, but generally the land is flooded at once and the floodings are repeated at intervals of two or three days during the whole time the crop is growing. On very porous soils, in dry bright weather, it is difficult to keep water always on the land; but on the stiffer soils especially those that have been puddled no such difficulty is experienced. The time paddy occupies the land varies in the different varieties; some mature in 20 weeks, while other kinds need 24 to 30 weeks. Taking 22 weeks as a fair average, a crop of paddy will probably receive during its growth, in addition to the rainfall, about 60 waterings.

Each ryot usually attempts to get as much water as he possibly can, especially when the only trouble he has to incur is to open a sluice. In some places the sluices are so arranged that only a certain flow of water may pass through when open, and the time the sluices are open is regulated by the area of land to be watered and the claims of the different persons entitled to the use of the water. But too frequently the sluices are made of an uniform size, and are out of repair, and there is then practically no control over the quantity of water used.

If a ryot is asked what quantity of water he uses for his paddy crop, all he can say in reply is, that he applies the water on each occasion to a certain depth over the land and at certain intervals. Of course the quantity applied at each time, as determined in this way, will depend on the state of saturation of the soil when the water is applied and will differ greatly. Assuming however that each fresh flooding follows immediately after the drainage of the remains of the previous one, and that the soil is saturated at the time, we may obtain some data by the aid of which the quantity of water used may be approximately determined. Assuming then that the figures above given are fair average ones, and that about 60 floodings, each to the depth of 2 inches on the land, are required to mature a crop of paddy, we find that the entire quantity of water used, will be equal to a depth of ten feet over the whole of the area irrigated. This seems to be an enormous quantity of water to use, but we have no hesitation in stating that, over a large area of South India, the quantity used is frequently much greater. If the soil was thoroughly worked and manured, half this quantity of water would be more than sufficient to bring to maturity a crop of paddy.

The paddy crop receives very little attention during its growth, beyond an occasional weeding which, as the ground is so soft, and the crop seldom grows in lines must generally be done by hand at a considerable expense. Harvest seldom begins until the crop is dead ripe; there is no doubt but that when cut in this state threshing is facilitated; but as the grain sheds so easily there is a considerable loss of it in the field, while the value of the straw as cattle food is considerably reduced. The crop is usually cut by means of a small lightly curved knife of 9 or 10 inches in length;

both smooth-edged and serrated-edged knives are used, and sometimes a hook is employed somewhat resembling a very small sickle. A reaping machine cannot be used with advantage, the plots being so very small, but a scythe of small size suited to the strength of the ordinary field coolie has been introduced and found useful. The crop is tied in small sheaves and after being exposed to the hot sun for a short time threshing commences. Paddy is very easily threshed. In many places in South India threshing is performed by striking the sheaf at the ear-end on a block of wood, 3 or 4 good strokes generally sufficing to separate all the grain from the straws. Sometimes short sticks are used for beating out the grain in the same manner as with a flail; but threshing is usually done in the ordinary way by treading by cattle. Threshing machines have been tried but have not been found to perform the work in a much more satisfactory way than the process first mentioned; the grain is so easily separated. It is very unusual in South India to stack crops of paddy. The crop is generally threshed immediately after harvest.—*Indian Agriculturist.*

GUTTA REGULATIONS.

Extract from the State Council Minutes

of 5th July 1888.

The Resident lays on the table correspondence containing recommendations of the Magistrate, Krian, and the Superintendent, Lower Perak, regarding the exportation of Gutta from the State, and says that about seven years ago an Order was issued to prevent the exportation of Gutta, because the trees were being rapidly destroyed, and it was feared that they would be completely.

It has now been found that so many Gutta trees are unavoidably destroyed by the extension of paddy and other cultivations, and by the collectors of firewood, that it is impossible to protect the trees which remain, and it is therefore proposed to revive the industry, which would afford a means of livelihood to many settlers who are at present entirely dependent on the paddy crop, having no other mode of obtaining their living during the months preceding the harvest.

Many of the poorer class of natives in Perak would also benefit by being allowed to resume this industry, which was carried on by them under the Malay régime.

After discussion, in which the views of the Malay members were fully considered, it is unanimously decided that the collection of Gutta shall be allowed to persons licensed by Government, such provision as is possible being made for the protection of the young trees, by the issue of an Order on the subject. The following Resolution is submitted by the Resident, and approved by His Highness the Sultan and all the members present.

It is hereby notified that from the 1st October next, the prohibition on the Collection and Export of Gutta will be removed, and Gutta of various kinds may be collected and exported under the following Regulations:—

1. Any person desirous of collecting Gutta must first apply to the Penghulu of the district in which he resides for a certificate that he is the possessor of at least one acre of cultivated land within the State.

2. Having obtained this certificate, the applicant may apply to the District Officer, who, after ascertaining the extent and situation of the land, title under which it is held, nature of the cultivation, &c., and that all Government claims upon it have been fully satisfied, may grant to the applicant a license which will entitle him to collect Gutta throughout the State.

3. A fee of \$5 shall be payable for this license, which shall be good for one year from the date thereof, but shall not be transferable.

4. Malays born in the State of Perak may be exempted from the necessity of being the possessor of one acre of land, and may obtain a pass to collect and export Gutta upon producing the certificate of the Penghulu of the district in which they were born,

and on its verification by the District Officer, and on payment of the fee of \$5.

5. All Gutta collected must, before being exported from the mukim, be reported to the Penghulu, whose certificate must accompany it to the port of export.

6. A royalty of one-tenth in kind or value will be payable at the port of export.

7. Trees of the kind called "Gutta Rambong" may not be cut down, but the Gutta must be drawn from them by tapping the bark only, and no Gutta-bearing trees, with the exception of "Singgrip," of less diameter than 8 inches within the bark, may be felled, except in places where the land is required for planting, mining, or other industrial purposes.

8. Infractions of these Regulations may be punished by fine not exceeding \$100 (One Hundred Dollars), or by rigorous imprisonment not exceeding two months, with confiscation of Gutta.—*Straits Times.*

DESTRUCTION OF COCONUT TREES BY BEETLES.

Extract from the State Council Minutes of the 10th July 1888.

The Resident invites the attention of His Highness the Sultan and the members of Council to the devastation committed by beetles amongst the coconut trees in Larut, Kurau, and Krian, where at one time there were a large number of trees, which in the former place have been almost, and in the last-named districts quite, exterminated.

This matter was before the Council last year, and money provided in the estimates. Major Walker undertook to endeavour to get the insect destroyed in the coconut trees near the barracks in Taiping, but could not find men willing to continue the work for 12\$ a month.

Mr. Creagh, then Assistant Resident, called for information from the Penghulus of Larut, who recommended a liberal use of salt among the branches of the trees, and filling up the holes already bored by the insect with the same material.

Dr. Simon's letter of 23rd May, 1887, published in the *Straits Settlements Government Gazette* of the 27th May, is read and explained to the Council, and, after discussion, the following is passed:—

Great loss having been sustained by the people in many parts of the State through the destruction of their coconut trees by the ravages of beetles, and H. H. the Sultan in Council having ordered that steps shall be taken to prevent the spread of this pest to such parts of the country as are not yet affected: It is hereby notified,—

1. That the owner of any trees which are affected shall be compelled to clear the trees of these insects within three months of notice given, under a penalty of \$1 for each tree so neglected to be cleared.

2. The trees shall be inspected by Officers of Police, in each district, and, in case of the owners failing to clear them by the end of three months, the tree shall be cut down, split up, and burned.

3. The \$1 fine for each tree being imposed in accordance with paragraph 1 of this Order.

The necessary expenditure for this work will be provided under a Supplementary Estimate as a Special Payment.—*Straits Times.*

ABANDONED FRUIT TREES REVERT TO THE GOVERNMENT.

Extract from the State Council Minutes of 11th July 1888.

The Resident lays on the table correspondence 2,554-1888, dated 10th July 1888, containing a letter from the Superintendent, Lower Perak, relative to fruit trees which are found on the land having been formerly planted by a settler, no claims for them being known. The Council directs the Superintendent, Lower Perak, to be instructed that such trees, where no owners can be traced, are the property of Government, and may be dealt with the land on which they stand, and should be made known to the public by a notice, the contents of which shall be published, and a notice shall be made to the public that any person who may have abandoned any such trees shall be allowed.—*Straits Times.*

PLANT-LIFE.

(From Mr. W. T. Thiselton Dyer's address to the Biological Section of the British Association at Bath.)

GEOGRAPHICAL DISTRIBUTION.

Perhaps those which are yielded by the study of geographical distribution are of the most general interest. The mantle of vegetation which covers the surface of the earth, if only we could rightly unravel its texture, would tell us a good deal about geological history. The study of geographical distribution, rightly handled, affords an independent line of attack upon the problem of the past distribution of land and sea. Here, however, we are embarrassed by the enormous amount of work which has yet to be accomplished. And unfortunately this is not of a kind which can be indefinitely postponed. The old terrestrial order is fast passing away before our eyes. Everywhere the primitive vegetation is disappearing as more and more of the earth's surface is brought into cultivation, or, at any rate, denuded of its forests. A good deal, however, has been done. We owe to the indomitable industry of Mr. Bentham and of Sir Ferdinand Muller a comprehensive flora of Australia, the first large area of the earth's surface of which the vegetation has been completely worked out. Sir Joseph Hooker, in his retirement, has pushed on within sight of completion the enormous work of describing so much of the vast Indo-Malayan flora as is comprised within British possessions. To the Dutch botanists we owe a tolerably complete account of the Malayan flora proper. But New Guinea still remains botanically a *terra incognita*, and till within the last year or two the flora of China has been an absolute blank to us. A committee of the British Association has, with the aid of a small grant of money, taken in hand the task of gathering up the scanty data which are available in herbaria and elsewhere. This has stimulated European residents in China to collect more material, and the fine collections which are now being rapidly poured in upon us will, if they do not overwhelm us by their very magnitude, go a long way in supplying data for a tentative discussion of the relations of the Chinese flora to that of the rest of Asia. I do not doubt that this will in turn explain a good deal that is anomalous in the distribution of plants in India. The work of the committee has been practically limited to Central and Eastern China. From the west, in Yunnan, the French botanists have received even more surprising collections, and these supplement our own work in the most fortunate manner. I have only to add for Asia Boissier's *Flora Orientalis*, which practically includes the Mediterranean basin. But I must not omit the invaluable report of Brigade-Surgeon Aitchison on the collections made by him during the Afghan Delimitation Expedition. This has given an important insight into the vegetation of a region which had never previously been adequately examined. Nor must I forget the recent publication of the masterly report by Professor Bayley-Balfour on the plants collected by himself and Schweinfurth in Socotra, an island with which the ancient Egyptians traded, but the singularly anomalous flora of which was almost wholly unknown up to our time. The flora of Africa has been at present but imperfectly worked up, but the materials have been so far discussed as to afford a tolerably correct theory of its relations. The harvest from Mr. Johnston's expedition to Kilima-Njaro was not as rich as might have been hoped. Still it was sufficient to confirm the conclusions at which Sir Joseph Hooker had arrived, on very slender data, as to the relations of the high-level vegetation of Africa generally. The flora of Madagascar, investigated by Mr. Baker, is perhaps at the moment the most interesting problem which Africa presents to the botanists. The flora as a whole presents a large proportion of endemic genera and species, pointing to isolation from a very ancient date. The tropical element is, however, closely allied to that of Tropical Africa and of the Mascarene Islands, and there is a small infusion of Asiatic types which do not extend to Africa. The high-level flora, on the other hand, exhibits an even closer affinity with the temperate flora, the ruins of

which are scattered over the mountainous regions of Central Africa, and which survives in its greatest concentration at the Cape. The American botanists at Harvard are still systematically carrying on the work of Torrey and Gray in the elaboration of the flora of Northern America. The Russians are, on their part, continually adding to our knowledge of the flora of Northern and Central Asia. The whole flora of the north temperate zone can only be regarded substantially as one. The identity diminishes southwards, and increases in the case of the arctic and alpine regions. A collection of plants brought us from high levels in Corea by Mr. James might, as regards a large proportion of the species, have been gathered on one of our own Scotch hills. We owe to the munificence of two English men of science the organisation of an extensive examination of the flora and fauna of Central America and the publication of the results. I am happy to say that the botanical portion, which has been elaborated at Kew, is all but finished. In South America I must content myself with referring to the great *Flora Brasiliensis*, commenced by Martius half a century ago, and still slowly progressing under the editorship of Professor Urbau at Berlin. The travels of Mr. Ball in South America have led him to the detection of some very interesting problems. The enormous pluvial denudation of the ancient portions of the continent has led to the gradual blending off the flora of different levels with sufficient slowness to permit of adaptive changes in the process. The tropical flora of Brazil, therefore, presents an admixture of modified temperate types, which gives to the whole a peculiar character not met with to the same degree in the tropics of the whole world. On the other hand, the comparatively recent elevation of the southern portion of the continent accounts, in Mr. Ball's eyes, for the singular proterity of its flora, which we may regard indeed as still in progress of development.

The Botany of the "Challenger" Expedition which was also elaborated at Kew, brought for the first time into one view all the available facts as to the floras of the older oceanic islands. To this was added a discussion of the origin of the more recent floras of the islands of the Western Pacific, based upon material carefully collected by Professor Mosely and supplemented by the notes and specimens accumulated with much judgment by Dr. Guppy. For the first time we were enabled to get some idea how a tropical island was furnished with plants, and to discriminate the littoral element due to the action of oceanic currents from the interior forest, almost wholly due to frugivorous birds. The recent examination of Christmas Island by the English Admiralty has shown, the process of island flora-making in another stage. The plants collected by Mr. Lister prove, as might be expected, to be closely allied to those of Java. But the effect of isolation has begun to tell; and I learn from my colleague, Professor Oliver, that the plants from Christmas Island cannot be for the most part exactly matched with their congeners from Java, but yet do not differ sufficiently to be specifically distinguished. We have here, therefore, it appears to me, a manifest case of nascent species.—*Gardeners' Chronicle*.

HEATED BORDERS IN THE OPEN AIR.—I send you a Pine-apple, and some Peach and Nectarine fruits ripened in my "Hypocaust," or heated earth garden, in the open air. One Peach and one Nectarine, supplied by Mr. Rivers for the purpose, with the fruit well set, were plunged in the hot earth, and the Pine-apple, a small-fruited sucker, was planted right out. This was in the first part of June. The peach and Nectarine never suffered a check and are now in healthy and luxuriant foliage. The fruits I send were attacked by slugs and so dropped. The Pine grew strongly, and the fruit, about the size of a green Walnut when put out, had become yellow and perhaps ripe, ten days before.—R. TREVOR CLARKE.—*Gardeners' Chronicle*.

CENTRAL CAYLAP TEA COMPANY.—[While the Darjeeling estates have been suffering from drought, the following is the fearful tale of damaging wet, told in the reports of this company.—Ed.] The season has been most unfavourable, and will be noted for the present mischievous hailstorms commencing from the latter end of March to the end of April; accompanied by heavy rain, 45" having been registered to the end of April. The plant by this time was so weakened by the hail and the damage from wind and cold, that they were attacked with a May blight epidemic, which hung on all through June; the temperature all this time ranged from 60° to 65°, being not too cold for growth, while the ground was sodden from the wet, so that comparatively little was done during May and June. The weather improved during July, and with it the flushes, and a fair quantity of tea was grown; but it is difficult to say how the season will result, some dry warm weather would grow large quantities of leaf, but if it continue as it has been, a gradual falling off in the returns may be expected; unfortunately also, our latest arrivals from August, the weather is reported as being "worse than it has been at any time during the season," so that the rain and continuous in flood, on the days the dews are full of stagnant water, so that the rainfall to 15th August, was 136" against 51" last year. Prices have been rather lower for fine Orange and Broken Pekoes, but better for the other qualities with peculiar character, especially for the Galle, Sept. 4th.

QUININE PRODUCE.—The Commercial Correspondent of the Times of India, writing on September 25th from London, reports—

A "bull" movement is appearing in quinine, and the chances of its being sent up to at least double or treble its existing value are discussed. In 1880 the manufacturers' prices for sulphate of quinine were about 12s per cwt., at the present time the price is only about 15s 6d per cwt. Ceylon has been the principal factor in bringing down the market. Now as no planting to speak of is going on—everything going way to tea—the forecast is that there will be con-

siderably diminished exports of cinchona from Ceylon in the next few years. "The very low price of bark," as one concerned writes, "will prevent much inferior produce being sent, and the impecunious owners of estates being now able to make both ends meet with their tea cultivation, all are of opinion which may result in manufacturers finding themselves short of the raw material they have in previous years been overstocked with. It is very easy and inexpensive to hold stocks of bark or quinine, and it would not require very much capital to hold all that was necessary, not to drive up the price of sulphate of quinine to 15s per oz. as was done some ten years ago but, say, to treble its present value."

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. III.]

COLOMBO, DECEMBER 1ST, 1888.

[No. 6.]

PLANTING AND AGRICULTURE IN FIJI:— PREDICTION AND FULFILMENT.

We take an article from the *Fiji Times*, in which the editor laments, that with the single exception of sugar, production in Fiji has fallen far short of what Sir Hercules Robinson predicted at the banquet given to him in Sydney on the occasion of the adoption into our Colonial Empire of the Fijian Archipelago. The soil is specially suitable for sugar, and for this article there is a good market close at hand. The same may be said of tea, if, which we doubt, a steady supply of cheap labour can be always counted on. Next to sugar, copra, and the other products of the coconut tree are staple exports, but it is in regard to bananas and other fruits that Fiji ought to go ahead, so that it may hold the same relation of fruit supplier to Australia that Jamaica does to the United States. We are not surprised at the decadence of cotton, once the high prices of the period of civil war in America collapsed. Cotton requires cheap labour, and even the cheapest labour in the world does not suffice to render the preparation of many plant fibres, beyond jute, profitable. As to rice, even here in Ceylon, we import about a third of what we use. While the natives of Fiji prefer root culture to rice growing, the latter cannot make much progress. Maize is an exhausting crop; but in Fiji it ought to be largely grown as a cattle feed. The whole question of production in Fiji, as in other tropical lands, depends mainly on abundance of cheap labour, and in this respect Ceylon has a great advantage over the Pacific colony. If the insane idea of the union of Fiji with Australia is carried out, the introduction of black labourer will be at once stopped in favour of the white labourer, and then Fiji will suffer as Northern Australia is suffering. The article in the *Fiji Times* runs thus:—

In December, 1874, Sir Hercules Robinson, the first titular Governor of Fiji, was invited by the leading merchants of Sydney to a complimentary banquet in honour of the annexation of this Colony to the British Crown. In speaking of the newly-acquired group, Sir Hercules said that—"The islands are unsurpassed in fertility, and are capable of yielding tropical and semi-tropical produce of every variety—such as sugar, cotton, maize, rice, yams, tobacco, fibre, and the several products of the coconut palm. Under such conditions, capital will assuredly flow into the islands, attracted by the prospect of profitable investment. The value

of property will increase. The great natural resources of the country will be developed. Fresh markets will be opened to trade. And the group, from its position, will become a centre from whence the blessings of christianity and civilization will radiate through the almost numberless surrounding islands of the South Pacific."

Leaving these blessings out of the calculation, inasmuch as they can scarcely be assessed at a money value, let us see how far the predictions of Sir Hercules Robinson have been sustained by actual fact, so far as tangible results are concerned.

Of sugar, there is no cause for the relation of a woful tale. Although prices have declined and the total values, therefore, appear lower in the Receiver-General's returns than is desirable, production has been and is on the increase. From 96 tons in 1875, valued, at the then current rates, as worth £3,417, or nearly £35 12s per ton, the export in 1887 had gradually reached 12,831 tons, valued at £205,294, or close on £16 per ton. Had values in 1887 been equal to those of 1875, the return for this article would have figured at £456,783. As it is, we must be content with the fact of increased production and the enterprise and industry of which it is the visible sign; and, still going on the same direction, hope for the speedy realisation of the brighter prospects which have been so long predicted.

It is a sad reflection on the Colony that the same spirit of steady progress is not only not to be observed with regard to cotton, but that studied and systematic neglect of this profitable industry has become thoroughly developed. In 1884, there were exported 150 tons, valued at £15,309, or £102 per ton. In 1887, cotton was evidently much higher in the market and was estimated as being worth something more than £120. Yet only 21 tons, returned at £2,894, were exported. Why, or wherefore, is one of the mysteries which hitherto have puzzled the political economist when attempting to forecast the future of Fiji from ascertained results.

The third article, to which Sir Hercules Robinson referred, was maize. During the last three years the export of this cereal has been pretty uniform, and the home consumption has probably increased. The high rate of freight and the risk of markets will always tend to keep this in the back ground as an article of commercial exchange; and it will only be when local supply largely exceeds local demand, and an arrangement can be made for carriage at a moderate rate that this will make any figure in the table of exports from this Colony.

It must be borne in mind that Sir Hercules Robinson spoke with authority. Not with authority merely official, but with the authority of one who had lived for a considerable period in tropical countries and was thoroughly acquainted with the conditions necessary to production. When, therefore, he referred to Rice as one of those articles for the growth of which Fiji is evidently suited, he was alive to the requirements essential to its successful cultivation. Those, he was convinced, exist here. Accepting that fact as unquestionable, what presents itself? The return of rice grown in Fiji during the last four years when the demand for the article is revealed by the inexorable logic of figures? No. But the amount of money sent out of the Colony, to the

extent of upwards of £40,000, in that period. A startling commentary on the neglect of those gifts of Providence from the intelligent appreciation of which so much was expected, and, sad to say, so little has been realised. The fact speaks for itself; it needs no marker.

Of tobacco there is none; of fibre but little exported. Both articles ought to figure largely in illustration of the material wealth of production of Fiji. Some hopes are held out of the former being grown and manufactured under skilled supervision, and when that arrives a prospect of success in the industry may be fairly looked for. This colony ought to produce as fine a leaf as can be found anywhere. It has been proved that it can do so, and knowledge and enterprise alone are wanting in order to secure the advantages of the growth. Fibre, in which the country abounds, shows a steady retrogression in place of natural increase. It has dwindled with lamentable regularity from 94 tons, valued at £1,031 in 1884, to 44 tons, estimated at £347 in 1887. A sad but emphatic commentary on the neglect of an article, the material of which is at every man's door and is, in many cases, a pest. That it might be made a means to competence, if not of absolute wealth, troubles nobody. The machinery necessary to utilise the raw material is cheap and its manipulation easy. Experience has demonstrated that the article can be manufactured; the falling off in the export has therefore to be accounted for.

If from these we turn to other matters, we find that with splendid pasturage and any amount of cattle, Fiji imported, during last year, butter valued at £2,281. With her seas, rivers and bays swarming with fish, she sent out for her consumption of that article in the same period, the sum of £1,758; with fruits, rotting for want of being gathered, and with sugar with which to utilize them growing on every hand, her bill in 1887 for jams and jellies amounted to £519; with an estimated export of tea for this year of upwards of 53 tons, she in the last twelve months, brought in about £1,150 worth of that article; and so on and so on, until repetition becomes wearisome.

In 1874, what did Sir Hercules say with respect to these. His words contain volumes of truth; will Fiji never profit thereby? His utterances of that day apply as well now and were to this effect:—

"All that is needed in order to utilise these vast natural advantages to the utmost is to seek to facilitate production; to increase the prosperity of those who labour, by cheapening the means of living; and to multiply commercial relations—giving to other countries of the superabundance with which Providence has blessed this, and taking from them in return what we ourselves are unable to supply—bearing in mind, as one of our greatest poets has so graphically expressed—

"The band of commerce was designed
To associate all the branches of mankind;
And if a boundless plenty be the robe,
Trade is the golden girdle of the globe;
Wise to promote whatever end He means,
God opens fruitful Nature's various scenes;
Each climate needs what other climes produce,
And offers something for the general use."

It is by acting up to the great principle inculcated in those lines—the principle of commercial association as distinguished from commercial isolation—that every portion of this Colony will attain the position she is qualified to occupy.

The country possesses almost boundless natural resources which require but to be developed. The true policy under these conditions must be to loosen every band that hampers industry—that interferes with free exchange—so as to lessen the cost of production; to extend our markets and by unmistakable exposition of the store of indigenous wealth with which we are blessed, to attract capital and population to our shores. When, when, will fact illustrate the truth of this?

The new feature in the above article in the *Fiji Times* (by a new editor) is that the Government and its land and labour policy are not denounced as entirely responsible for the absence of enterprise and progress described.

A VISIT TO THE NEGOMBO DISTRICT:

THE GREAT CINNAMON REGION OF CEYLON RE-VISITED AFTER HALF-A-CENTURY—THE CINNAMON TRADE—THE BASE LINE—REMINISCENCES OF THE "DAYS OF OLD"—THE CEYLON CROCODILES—A NOVEL MANURE FOR COCONUT TREES—VARIETIES OF CINNAMON.

GOLTAPOKUNA, KADIRANA, Oct. 23rd, 1885.

A period of well-nigh half-a-century has elapsed since I first made acquaintance with this the great cinnamon region of Ceylon. Poor Wm. Ferguson was then commencing his career in Ceylon as a Sub-Assistant Surveyor, and was taking part in the operations preliminary to the sale by Government of its cinnamon plantations and the final abandonment of the once profitable trade and monopoly in the spice. Our Dutch neighbours in Java had gone far enough in experiments to show that Ceylon had no natural monopoly in the growth of cinnamon, although then and still, as in the case of plumbago, it possesses a monopoly of the best and finest kinds. And so the decree had gone forth for the sale of the Gardens and the absorption of the Cinnamon Department in the general Service, although for years subsequently a revenue accrued to Government from exorbitant duties on the world-famed spice, which is supposed to add sweetness to the breezes which "blow soft o'er Ceylon's isle." Monopoly prices, heavy export duties, and I am sorry to be compelled to add, adequate profits on the private capital and industry embarked in the private enterprise of cultivating and preparing cinnamon, have long been matters of the past,—the long ago,—the ancient times which many think were better than these. In those times I made the acquaintance of "the base line" which would be undervalued only by the class described by Sydney Smith as capable of "speaking irreverently of the equator." We saw the towers too, which are not only to be repaired but to be raised, each of the two, by 30 feet of additional height. They will then, I suppose, be more useful than ever before as aids to a strictly correct trigonometrical survey of the island, to become the basis of detailed cadastral surveys.

At the time of which I write the Government cinnamon department and the special importance of the Mahabadda were not mere traditions. Walbeoff, the head of the department, had been killed by being thrown against a tree while riding, but the Rajepaksas, name inseparably connected with our special spice staple, were in full force, and I suppose it was the uncle of the benevolent old Sampson whom I met on the occasion of my visit, when I was a black-haired, red-cheeked lad, instead of an old man "withered at the top" as my good friend Dr. Elliott used to say of grey hair. Mr. Walbeoff had been wont to hold Court and administer justice in the building set on a cabook-hill whence I now write, while Waring's and Walker's bungalows were household words. The Walker referred to, whose bungalow was at Colombo, was uncle to Sir E. Noel Walker as well as to Mr. John Marsh. With the ignorance of short acquaintance with the country and the natural impetuosity of youth, my brother and I thought it well—after a long walk through the laurel-like fields, during which we shot a "jungle pheasant," popularly "jungle crow," but scientifically the species of Indian cuckoo which shouts "Ouk! ouk!" and which made a very tough curry,—to have a bath in a deep pool of the Mutwardiya river. While dashing and splashing about in the water, I was surprised to see what I took for dark-coloured logs of timber, bobbing up and down in the water. It turned out that we had been bathing in the midst of a perfect shoal of gavials. They did not attack us, and I have never heard of any human being falling

victim to the crocodiles of this region. So it is with the crocodiles of the ponds and marine streams of the Jaffna Peninsula: they always scuttled away from us to take refuge in the water. And from Hornaday's account of the leprous and lamished and *cannibal* crocodiles of Mullaitivu, they are equally innocuous as regards man, although they fought for the carcases of their fellows. I have just heard from my friend here, Mr. Wm. Jardine, that on the occasion of a year of great drought in the Jaffna Peninsula, during which pond after pond dried up, the crocodiles concentrated in one larger lakelet where the water held on. Here 500 of them were captured, slaughtered, and their carcases applied to the manuring of the coconut palms. That was man's revenge on the species for the sins of individuals in other parts of the island, such as the crocodile at Batticaloa which made a vacancy in the Dutch Civil Service, by swallowing and digesting a Collector, the buttons of whose uniform subsequently revealed the mystery of his fate. Not at Batticaloa alone has the fierce voracity of crocodiles been proved, a different variety surely to the sluggish creatures I have been speaking of. But sluggish as they may be I should not care to repeat the experiment of that bath of long ago.—Cinnamon is more prevalent than ever in this its favourite region, though not now cultivated and prepared, except on this and a few other estates with the care and attention which high prices formerly justified. Of this plant as of others there are distinct and greatly differing varieties. The natives appreciate four well-known kinds of cinnamon, of which one is of a far higher jet, giving a much finer bark than the others. On this estate all supplies are confined to this high-class variety. So in regard to coconuts, the cultivation of which has made such enormous progress in the half century, only the best, perfectly mature, round-shaped nuts are chosen to propagate from, while the culture of the palm is reduced to a science. But here I must stop, although, when I sat down to write, I intended to give an account of my trip hither via Negombo. But the rest must await a more convenient season.

THE CORAL INDUSTRY AT LEGHORN.

The coral industry, having flourished in Italy—its principal markets being Naples, Genoa, and Leghorn. Its importance has, however, greatly diminished. The price of worked coral, which was £11 7s per lb in 1883, fell to £10 15s in 1884, to £7 5s in 1885, and to £3 12s 6d in 1886, and 1887. Owing to this great decline, the value of the export from Leghorn fell, during the period between 1885 and 1886, from £151,936 to £124,184, a diminution of about 12 per cent., though the quantity *increased* 10 per cent. A slight rise in prices took place during 1887, but there is no reason to suppose it will be maintained. This great fall in prices, which has been so disastrous to the Leghorn coral industry, is due in large measure to the enormous quantities obtained at Sciacca in Sicily. Geologists suppose that some submarine eruption has occurred there and raised large quantities of coral within reach. Thus raw coral of medium quality has fallen from 3s 7d per lb. to 1s 1d and even lower. I have seen cases of Sciacca coral, small and broken at best, and of the worst quality bought at 2½d per lb. Ten years ago the same thing would have fetched about 6s. The most prosperous period of this industry was before 1880, when the new Sciacca reef was discovered.

The greater part of the coral worked at Leghorn is exported to Padua, Finland, Russia, the Balkan Peninsula, and Asia and Africa. Each country has

required from time immemorial a special kind of make, necklaces of round pearls, or of oval, heavy, medium, small, cubical or irregular kinds. In spite of the general depreciation in price, the best kinds are still very dear; an uncut piece of the size of a pigeon's egg of deep shade and perfect, is still worth £32 to £40. Ten years ago it would have been worth £64 to £72. These choice pieces are chiefly sold for ornamenting the head-gear of mandarins, or the turbans of rich mussulmans. Rose and milky, as also clear colours, are less valuable than deep shades. The best shades come from Cape Vert. The export to certain countries is diminishing, because coral is ceasing to be used as money, but there are still large quantities sent to Abyssinia, the Congo, the Cape, India and Ceylon, Siberia, Japan, and China. The uses to which coral ornaments are put in many countries are often unknown even to the merchants who trade in them. It is supposed that among barbarous or half-civilized peoples, they are used to ornament arrows, lances, and pikes, and that corpses are decorated with them before interment. Formerly, the Italian peasants, especially in Central Italy, bought coral largely for ornament, feeling sure of being able to sell it again without difficulty in case of need, as it was easily realizable, but in consequence of the recent fall in prices, they have lately largely abstained from such purchases.

Many houses in the coral trade at Leghorn are now closed, chiefly those with small capital. The industry formerly employed about 10,000 women here, nearly all of whom worked at home, but now only 6,000 are thus engaged. In spite of this, the quantity of coral exported from Leghorn has nearly doubled since 1882, owing to the fact that now-a-days there is a much larger proportion of inferior quality, requiring less workmanship. No machinery or mechanical process is used, the workman takes the pieces into her hands one after the other, and according to their thickness, quality, and defects, works it into a certain form. The women earn from 7½d to 1s 3d per day. Sciacca coral is chiefly employed on account of its low prices, and has considerably lowered the value of the old fisheries of Sardinia, Algeria, Spain, Portugal, and Japan. There is very little demand in Europe for coral, and it seems an article most suitable for barbarian and semi-civilized nations.—*The French Consul at Leghorn.—British Trade Journal.*

TEA AND POWDERED MILK.

The latest novelty in connection with tea is that just introduced into this country by the London representative of the Swiss Milk Company of Gossau—St. Gall, Switzerland, Mr. Carl Lawinski, of 59, Mark Lane, E.C. This preparation consists of a mixture of tea—purchased originally in London—and the desiccated milk powder of this well known firm. I have had several of their productions to test, and it may interest your readers, to whom tinned milks are often a necessary makeshift, to learn something authentic about this latest innovation in their preparation. By this strange new combination of tea and powdered milk, I was tempted to investigate some of the other preparations, and as these will be better appreciated by your readers than the tea and milk, the results may as well be included in this account. First of all as to the milk itself. This is prepared by a special process by which the aqueous constituents of the splendid and rich Swiss milk are all evaporated, and the result is a fine powder containing all the nutritive constituents and flavour, and only requiring the resubstitution of water to reproduce the full characteristics of the original milk. I may as well endorse this by stating that the *Lancet* has had the various milk powders of this firm tested by careful analysis, and was thoroughly satisfied as to their purity, which is guaranteed and speaks of them as "highly nutritious food."

There are three preparations of the milk itself,—viz.; (1) the dry solids of pure cream milk, (2) the dry solids of skim-milk, and lastly, a mixture of milk, powder and sugar. Personally I venture to join issue with the *British Medical Journal*, on the preparation of most importance, as I fear the cream-milk (No. 1 above) is too rich owing to the original richness of Swiss milk as compared with other milks—and No. 2, above, is probably the one which will be found both the most readily digestible and the most palatable. It contains 0.20 of fat, as compared with 21.80 of fat in No. 1. These preparations are made up in tins for export, one of tin No. 2 containing enough to produce 1 litre of milk, over an imperial quart. Their keeping qualities as compared with fluid condensed milk are said to be far better, and this seems reasonable. As ordinary condensed milk contains from 25 to 30 per cent of water, it is obvious that powdered milk takes up less space in packing, and is lighter in weight. The absence of water, in itself is a sound reason for supposing that it will keep longer in warm climates, and longer when opened, than condensed milk. So much for the milk itself. The new departure I am referring to is the admixture of chocolate, coffee and tea, by which cups of ready prepared coffee, chocolate and tea, can be produced wherever hot water is procurable. I have tried the tea, and two forms of the chocolate. As to the tea, all I can say is that this of course depends upon the quality of the tea employed—and this being China at present would hardly recommend it to people accustomed to Indian tea. Still it is a fair quality of China, and I have tasted much worse at Hotels in this country. The tea and milk, however, is not a combination that will be in much request in India, the home of tea. The chocolate and milk preparations on the other hand I can safely advise your readers to try. One form is in that of tablets or cakes, the other in powder. Both make exceptionally well flavoured chocolate, when prepared as in my case, that is *boiled* and stirred for a minute or two, as all chocolate should be. The tablet form is much more highly flavoured and far richer in fat than the other, which latter (the powder) is consequently probably more digestible and better suited for India, resembling as it does Cocolina prepared with milk, without the trouble of having to procure or to add the milk. Either of these is infinitely superior to any form of "Cocoa and Milk" I have yet tasted. The Government have taken these preparations up.

P.S.—I would point out in connection with the remarks in the *Standard's* article, upon the price of Dr. Johnson's tea, that in his day the freight was very much heavier than now, and the duty, instead of 6d per lb. all round, was as follows:—

	In	s	d	£	s	d
1728	the duty was	4	0	per lb. plus	13	18 7½ per cent
1760	"	1	0	"	43	18 7½ "
1782	"	1	14-5th	"	55	15 10 "

PERIPATETIC PLANTER.—*Indian Planters' Gazette.*

MR. W. J. FORSYTH IN HAWAII.

A copy of the *Daily Pacific Commercial Advertiser* of August 30th from Honolulu contains the following parliamentary report, showing that an old Ceylon planter is still to the front:—

THE LEGISLATIVE ASSEMBLY.

WEDNESDAY, Aug. 29th.—The House met at 10 o'clock, the President, Hon. W. R. Castle, in the chair. Prayer by the Chaplain, Rev. E. S. Timoteo. Minutes read and confirmed.

MINISTERS ANSWER QUESTIONS.

Minister Thurston read the following, in answer to Rep. Nakaleka's questions:

1. The appropriation for the encouragement of the cultivation of cinchona has been disposed of as follows: Cinchona seed, \$168 70; Mr. Forsyth's services to February, 13th 1888, \$412; \$580 70. The balance of \$1,429 30 remains in the Treasury.

2. That Mr. Forsyth has been in the employ of the Government from August 13th, 1887, to July 31st, 1888.

3. The salary which was agreed to be paid Mr. Forsyth was \$200 a month, he paying his own travelling and other expenses.

4. The Government has not given any I. O. U.'s for Mr. Forsyth's salary. Through inadvertence he did not draw the salary due him between the 13th of February and the end of March. Since the lapse of the period and consequent lapse of the unexpended balance of appropriation, there has of course been no payment to Mr. Forsyth. He has rendered several bills to the Government on the basis above stated up to and including the 31st of July, which I have approved, and which I have told him would be paid upon the passage of the appropriation bill, out of any available appropriation.

5. The propositions made by Mr. Forsyth and the proposed action of the Government were stated at the time the appropriation was asked for in 1887. It was in brief as follows:—Mr. Forsyth was on the ground with unquestioned evidence that he was what he represented himself to be, viz., a practical coffee and cinchona planter and cultivator, who had been employed as an expert in other countries in connection with the introduction of such industries. He proposed to the Government and his proposition was accepted, that he should make a detailed examination of the different districts of the Kingdom, and report upon the suitability of the same for cinchona and coffee culture; and at the same time to disseminate information and stimulate an interest concerning the same.

The question of developing these industries and the best methods of so doing received much personal attention on the part of myself, and was considered a number of times by the Cabinet. With regard to cinchona, investigation showed that from several causes the prices had declined to such a figure that there was little profit. But with coffee the outlook was entirely different. Statistics show that the consumption is increasing faster than the production, and the price steadily rising. After much discussion of different plans it was decided, with the concurrence of the Cabinet that a system on the lines of the bill which has been passed by the House, would best accomplish the object, and Mr. Forsyth was informed of the action proposed, and an outline of the proposed Act was given to him with the statement that the Government would introduce a bill in accordance therewith. He has acted on that information, and has done his best to create an interest in the subject, and as a result of his efforts, in conjunction with those of the Government, I am assured, by those who are willing to invest their money, that the capital will be forthcoming to place the plan proposed by the bill in operation.

As to what has been accomplished by engaging Mr. Forsyth's services, his report in the Interior Report speaks for itself, and it is saying no more than the truth to give him the credit of having overcome the well nigh universal indifference and opposition and created the present interest in the industry which is felt in the community.

Had it not been for the efforts of Mr. Forsyth, and the interest created by him, the subject of coffee cultivation would not have been brought before the House this session. As a result of the action of the House I hope and expect that, under the bill referred to, a thorough and well equipped coffee plantation will be inaugurated within the next few months. I propose to pay for this service out of any proper appropriation made by the Legislature and shall propose an item for that purpose which by inadvertence have been omitted from the estimates.

A Bill for the promotion of Coffee was, however, afterwards vetoed by the King.

HIGH-PRICED NILGIRI TEAS.

Ceylon is favoured at present with a visit from Mr. Thomas Stanes, proprietor of Glendale and other tea and cinchona estates on the Nilgiris. Mr. Stanes is interested in seeing what is being done in Ceylon Tea factories and will spend a few days this week in the Central Province. In the circular of Messrs. Gow, Wilson & Stanton for Sept. 28th, we find Glendale entered for 36 boxes of orange flowery pekoe at 3s. per lb.

and 3½ boxes at 7s 6d ! So that Mr. Stanes' manager on Glendale knows how to make Fancy teas. The latter at 7s 6d, Mr. Stanes tells us, was a special green tea and valued in Calcutta at 10s. So large is the local demand throughout India for Glendale teas that very little so far has ever been sent to London. Glendale is situated at about 6,000 feet altitude. Mr. Stanes tells us that a large portion of his fuel supply has for years been got from his plantation of blue gums which he regularly coppices with satisfactory results. We trust Mr. Stanes will enjoy his visit to our hill country.

FIFTY MILES NORTH OF COLOMBO :
THE RAJAKADALUWA PLANTING DISTRICT.
COCONUTS—PLANTAINS—CASSAVA—COTTON—PALMYRAS.
THE ENCOURAGEMENT FOR RAILWAY EXTENSION TO
CHILAW.

Through the absolute disposal of all suitable land in the districts south of Chilaw, enterprising pioneers—native, burgher and European—interested in the extension of coconut planting have been forced to look farther afield and in some cases to take up Crown land north of Chilaw, and even beyond the Deduruoya, in order to fell the forest, clear the land and plant the popular palm. This process of extension began some years ago ; and now at several points along the road to Puttalam, there are plantations or young clearings, of more or less extent, of coconuts. To the eye of the visitor or passing traveller, the country beyond Chilaw is certainly not prepossessing for planting purposes. It looks, and it certainly is, a dry and thirsty land. The sombre forest and apparent absence of large timber trees add to this effect, as also the sandy appearance of much of the soil. But on the other hand it must be confessed that I and a fellow-traveller saw the district under perhaps the greatest disadvantage, towards the end of a very protracted, exceptional and trying drought. And yet, notwithstanding such an ordeal, the coconut trees we inspected up to three and even five or six years, stood up with full health and looked wonderfully green and vigorous, so much so as to draw forth expressions of astonishment from my companion, an experienced coconut planter.

The Deduruoya runs to the sea a little north of Chilaw. The ferry is about two miles from the town. There are coconut clearings on both sides of the road between the town and the river. Older trees near native huts and villages are not wanting, but they scarcely afford a sufficient criterion of what plantations may come to. The unbridged Deduruoya is a decided obstacle to traffic and to progress in that region. It cuts across the main road between Chilaw and Puttalam, and it is one of those unmanageable rivers that nothing but a substantial bridge can conquer. Rising amongst the West Matale hills, rains in that region speedily tell on its flow, and in monsoon times—as doubtless at this present moment—the river runs bank high, in an exceptionally deep, wide, rushing, raging torrent. In a time of flood, the ferry beyond Chilaw presents this wide, rushing current, and with debris tumbling down no ordinary boat can ply with safety, so that often for a week at a time, communication is cut off between the North and South of the district and between Puttalam and Chilaw.

Successive Government Agents have frequently urged the bridging of this river and none more forcibly than Mr. Lushington, and the result is that now we have travelled over the ground and seen the continuous scene of cultivation and population between both rivers, we certainly cannot be coming back to the opinion of this able and able officer. Railway Extension is not only to Negombo, but all the way to Chilaw if not beyond. We do not see at this moment any immediate prospect of Government

carrying on the Railway even as far as Negombo ; although we feel that if a certain fixed sum were taken from surplus revenue henceforward every year for Railway Extension, more good would probably be done to the people and country than through further irrigation schemes. But whether this desirable bit of Railway Extension be taken up next year or only several years hence, one thing may be urged with a clear conscience and that is, that both the Mahaoya at Toppu and the Deduruoya beyond Chilaw should be bridged without loss of time, and that the bridges should be of iron and of so big a pattern and so strongly constructed as to be suitable to carry both road and railway when the day for laying the line arrived. This would undoubtedly prove true economy in the end for all concerned.

It is clearly an immense check on ordinary trading when an unbridged river and ferry toll intervene as at Toppu, to keep fruit sellers, carters &c. away from the natural markets ; and again when planters and coolies are liable as they are beyond the Deduruoya, to be cut off for a week at a time from the source of their grain supplies, the Chilaw bazaar. When we crossed the latter river, it was probably at its lowest, with the current confined at the Northern side to one-third or fourth of its whole bed ; the rest presenting a wide extent of sand through which it was painful to see bullocks dragging a loaded cart with the greatest possible difficulty. Of the cartroad on each side of the river, we have to speak in high praise. It was in capital order and so well constructed, so well-barrelled with deep side drains as likely to continue good for a long time.

Coconut clearings begin at once on the North side of the Deduruoya, the chief proprietors in this neighbourhood being members of the family of the late well-known Proctor Cooke of Chilaw and they on the whole, seem well pleased with their investments. We saw some exceptionally good soil on one of these properties with correspondingly luxuriant trees. Rajakadalawa, the terminus of our journey, is some 1 mile north of the river, and here Mr. G. D. Miller (formerly of the Ramboda, Dikoya and Matale districts) has with great pluck and industry, pioneered and opened for himself within the last three years, as many as 250 acres with coconuts. Mr. Miller is now opening fresh clearings on behalf of constituents and altogether quite an impression has been made on the "wilderness of jungle" at this point. My companion's experienced eye was not quite satisfied with the generality of the soil : it was of that porous, comparatively light description, in which though the coco-palm may rejoice for 8, 10 or 12 years, he thinks will then require liberal treatment in fertilising material to keep the crops of nuts up to the mark. At the same time, it is a soil which can be conveniently dealt with and which will absorb moisture very readily. As it is, water even at this very dry season was found at an easy depth, a fact that partly explained the healthy, vigorous appearance of the young palm trees. The lay of the land altogether is simply perfect, and though the jungle of the Rajakadalawa district—does the district take the name from the principal estate or *est. casa*?—cannot be considered heavy, yet there is a good deal of marketable timber, more particularly ebony, for which a sale can be got. The most noticeable fact connected with the cultivation as reported, next to the flourishing condition of the young coconuts (the oldest being about three years) was Mr. Miller's very successful intermediate culture of plantains. These grow very readily and flourish exceedingly, yielding rich crops ; and in the opinion of both planters and

distinctly benefit the coconut by shading the young plants during the most trying period of their lives; while, after three years, the plantains are entirely rooted out and the palm gets the full benefit of all the space. In other parts Mr. Miller had an equally flourishing crop of cassava which grows luxuriantly and which he sells to the villagers at 6 cents a plant, the purchaser taking up the tubers and leaving the tops in a way to be restored to the soil. The tubers of one plant were considered to serve a family of five or six persons for a week and all for 6 cents! The nutritious qualities of the cassava are highly appreciated by the Sinhalese and Tamils of the Chilaw district. Most of the work on the plantations in this district is done by the villagers on contract and the good effected amongst them by the opening up of large plantations is particularly noticeable and duly appreciated. As usual, the natives have begun to follow the example of the European pioneers by clearing and planting small gardens along the road, more especially up to the next river, the Battuloya, but ere long we shall doubtless see the whole of the roadsides between Chilaw and Puttalam taken up and occupied. Mr. Miller acts as the Medical Officer pretty well for the whole of his district: such confidence have the people in his skill that they come long distances to be treated surgically as well as "with potion and with pill" and the poor people are not wanting in gratitude to their European benefactor.

We need not say that the Rajakadalwa country is a good one for sportsmen: elk, spotted deer, pigs, hare, junglefowl are plentiful enough, while bigger game are not wanting in jackals (rather too abundant), crocodiles (a young one was being raised at our friend's bungalow), cheetahs and elephants. Mr. Cooke had been troubled by a herd of elephants shortly before our visit and had to collect all his labourers and neighbours to help to drive them away, while as for cheetahs, the biggest we have ever seen—looking more like a lioness in size—sprung quietly out of the jungle and crossed the cartroad, looking leisurely up and down, about 200 yards in front of our bullock cart. The planter who is fond of sport need never therefore feel time hang heavy on his hands. The unhealthy time of the year in the district is February-March, and then Mr. Miller's experience teaches him it is best to take a holiday trip to avoid fever and recruit for another spell of lowcountry life. The influence of the seabreeze—the coast not being over 3 miles off,—is felt for the greater part of the year:

As an instance of the difference transport makes, we may mention that R18½ per 100 bunches of his plantains given to the planter at Rajakadalwa, pays him better than R40 for the same quantity, would in Colombo—the difference barely covering the cost of transport and expense if sent and sold in the capital on his own account.

At the end of these hurriedly written and rather disconnected notes, we can only just refer to Cotton-growing as an industry which we consider peculiarly adapted to the northern portions of the Chilaw and Puttalam districts. The climate and soil would we think, do well, and samples we brought from fine vigorous shrubs at Rajakadalwa, have been reported on as follows by Mr. Mitchell of Messrs. Darley, Butler & Co.:

"The sample of cotton is of the kind the Sinhalese call 'kapu,' has an excellent staple, and would be admirably adapted for spinning purposes. It is what is commonly called 'Fiji' cotton, and the growth of it should be extended as much as possible, for the Spinning and Weaving Company will buy all they can get of it. Without seeing the seed, I should say it is from the perennial shrub, that grows some 6 or 8 feet, and goes on yielding almost without

stopping. This kind would give the minimum amount of trouble to the cultivator, and is easily separated from the seed. There is a grand future before the natives of the country if they can be induced to grow such cotton, and that it will grow is now beyond doubt, for it has been in the island for many years, and is believed to have been brought by the Portuguese from South America."

There are extensive resources in fairly good jungle in the district referred to,—a depth inland of perhaps ten miles of forestland being untouched,—and the Assistant Agent for Puttalam (Mr. Lushington) as also for Chilaw (Mr. Saxton) will, we feel sure, supply any needful information to intending planters of cotton, coconuts, palmyras or tobacco in that region. The Chilaw district has only been separately established under Mr. Saxton's care from the beginning of this year, and everywhere we found this intelligent, obliging officer, highly spoken of by the people of his district.

[Just as we were closing the above, the Administration Reports for the North-Western Province came to hand, and we find that as usual Mr. Lushington has supplied a very full and able Report on his district which, for last year, included Chilaw as well as Puttalam. Mr. Lushington specially alludes to the extension of new industries in coconuts and tobacco and he enlarges on the Chilaw Railway after a very practical fashion. We shall quote fully in early issues. Mr. Lushington makes one curious blunder: in affording a comparison between the "days of old" and 1887 in his district, he refers to Casie Chitty's "Gazetteer" as for 1828: it was published in 1834.]

COTTON GROWING IN CEYLON.

In answer to a Hanwella correspondent we say:—Land liable to be flooded will scarcely do for cotton. Still you might try an experiment on an acre first; plough or fork the ground; buy a few lb. of seed from Messrs. Darley, Butler & Co.; dibble 2 seeds in each hole with a stick, 2 inches in ground at 3 feet apart, or say 3 by 4 feet, getting 3,500 plants to the acre; put the seed in now in wet weather and it ought to be above ground in a week or two and then the crop comes 6 months after in dry weather, can be gathered by hand, packed and brought into Colombo to be cleaned in a "cotton-gin." Mr. James Blackett dibbled in seed (2 in each hole, 2 inches deep) over 100 acres with 1 cwt. of seed, and his shrubs a few weeks old are about a foot high.

SINHALESE LABOUR ON TEA ESTATES IN THE LOWCOUNTRY.

It is quite evident that we are on the eve of a notable revolution in the circumstances attending the cultivation of a large area of European plantations in Ceylon; and it will be well for the Government of Sir Arthur Gordon to recognise the fact before they legislate for simply Immigrant cool labourers on such plantations. If, as is rumoured, the Governor entertains the idea of sweeping away all special legislation and other differences between Sinhalese and Tamils, immigrant or otherwise, in respect of medical treatment, quite as necessary will it soon be to legislate for the relations between planters and Sinhalese as between planters and Tamil immigrant coolies, in respect of wages, terms of agreement, and so on.

During the "coffee" era, only under rare circumstances did the Sinhalese come to work on the plantations of Europeans, and when they did, it was after a most erratic fashion. Very few of the coffee districts adjoined the villages of a class of natives poor enough to need the help which extraneous wages would supply. No coffee estates existed within the bounds of what we now recognise as the "lowcountry," and even when Sinhalese could be persuaded to come and help in

picking coffee berries during a time of big crop, daily or at longest weekly wages with leave to go to their own houses every night, was generally the stipulation where such labour was employed.

The case is very different now. Our "lowcountry" in the Kiburi Valley, Labugama, Kalutara and all down the Western and Southern coast districts as far as Mutara is being gradually but steadily—in some districts very rapidly—covered with tea plantations. These districts are surrounded in many cases by Sinhalese villages and often by a class of very poor people ready to do a good day's work for the much-coveted regular food and wages offered by the planter. So much is this the case, that the Sinhalese are even ready to leave their villages and in some instances travel a good many miles, to take up their residence in "lines" (huts) provided by the planter. They also receive advances of food in coast rice which they are glad to have as country-grown grain, and work steadily on for a month at a time, only after that period claiming settlement of wages in full. Here we have several of the long-cherished notions respecting Sinhalese labour knocked on the head; but more than that we have the authority of a gentleman—Mr. W. J. Forsythe of Nahalma, who is perhaps the largest employer of Sinhalese labour on any one plantation in Ceylon,—for saying that he finds the Sinhalese, men, women and children ready to work alongside of or even among Tamils and under the control of Tamil kanganyes. Mr. Forsyth has as many as 150 Sinhalese helping to pluck his tea and doing other estate work. Some of them have come from villages 15 miles off. They come in family groups and make themselves comfortable in their "lines" and stay on for a month at a time—that is they are pleased if paid up about the 27th or 28th, and allowed three days' leave on condition of returning to work on the 1st of the following month. No advances are given, but rice is supplied from the outset, and a very few weeks are sufficient to show a great change for the better in the health and bearing of these Sinhalese from the effects of the regular and ample supply of food they receive.

We should have mentioned that although there are no money advances paid to the Sinhalese who come to work on tea estates, one main inducement in some cases is that afforded by giving the head of a party of villagers—their leader—five cents a day, the head man may pay the easy Sinhalese of his village turning out to work. In this way, the headman who brings 20 labourers, earns his rupee a day for doing nothing. With reference to Sinhalese working with Tamils, a Colombo merchant informs us that he has just engaged for the Kiburi Valley estate a gang of 20 Sinhalese and 9 Tamils under a Sinhalese kangany, who made the journey to the estate in order to have his usual gang of 20 men, women and children taken on!

All this is very interesting; but it also conveys a lesson prominent with the promise and potency of greater things in the future. We may be sure that thousands of our rural population now earning a very precarious living,—eking out their small portion of rice with fruit and roots,—will soon enjoy the example of their neighbours when they learn the comfortable results to them of such occupation. To work on the tea estates will be in the majority of the Sinhalese in the poorer lowcountry districts, and we have the Governor and his Executive Council in the hands of a very wise man the time when through their many wise planning devices there will be a large Sinhalese class in the island, Tamil and European side. One advantage from the change will undoubtedly be that the money earned, by means the food supplied, will be spent in the island in place of being taken away to India.

DRUG TRADE REPORT.

LONDON, October 14.

ANNATTO.—Very dull, at 2d per lb. for good Ceylon Seed, three bags fair quality but mixed with tea sold at 1½d per lb, today. We hear that the cultivation of annatto is being very largely extended in Ceylon at present.

CINCIONA.—At today's auctions only a few parcels were offered, but no attention was paid to them. South American flat Calisaya, good bright, partly sold was bought in at 1s 10d for damaged to 2s 3d for sound. Thirty-two cases Ceylon bark, bold heavy silvery, but slightly-damaged Succirubra quills were bought in at 1s per lb., an offer of 9d being refused.

The exports from Java during the month of July, the first of the season in that island, have been remarkably small, the figures for the month, as compared with its predecessors, being:—

	1888	1887	1886	1885
	lb.	lb.	lb.	lb.
Private	162,980	219,787	171,566	51,609
Government	11,021	76,699	49,549	66,162
Total	174,001	293,486	221,115	117,771

OILS (ESSENTIAL).—Citronella: It is said that there has been a little more life in the article, but prices still remain quoted at 3d to 3½d per oz. for native brands. At today's auctions 10 cases bought in. Clove oil has advanced to 5s per lb. in sympathy with the rise in the spice. Essential oil of Almonds can still be had at 25s per lb. Cinnamon leaf oil neglected at 1½d per lb. Three cases Spanish Eucalyptus oil were offered and bought in at 1s 10½d per lb., ½d less being declined. French Lavender unchanged. A parcel of about 500 oz. "Neroli" sold again without reserve at 6d to 7d per oz. Japan Peppermint is reported in somewhat better request privately, but there is still plenty offering. American oil firm at 14s 6d per lb. for H.G.H. American Spearmint (H. G. H.) quoted at 15s per lb. Otto of rose is said to be dearer in the East. Prices here are firm. As regards Mitcham oils, the future of the market, this week has been the demand for Chamomile oil, of which very little is now left in the growers' hands. The price has advanced about 10s per lb., viz. to 52s. 6d to 55s, and there is very likelihood of a further advance, as the demand is not yet satisfied. The total quantity of this season's oils put at considerable under 200 lb. Peppermint is dull and almost neglected at about 24s to 25 per lb., but there seems every appearance of an advance shortly. In Lavender there is nothing new.

QUININE.—There has been a further decline this week, and considering besides German in bulk are offered, first at 1s 5d and subsequently at 1s 1½d per oz., although it appears that at the close there is some what better demand, which buyers at the latter figure. At the auctions 7,500 oz. Auerbach quinine in 100 oz. tins were offered for sale. The holder would have taken 1½ 3½d per oz. but could only realize 1s 3½d at the auctions, and bought in the whole lot.

CASTOR.—150 tins were rather pressed for sale today, and mostly disposed of at a decline of half a penny for medium and good lots; common dry fox at 1s 3d, rather brassy chocolate 2s to 3s; ordinary door flavour, slightly crystallised 5s to 6s, 4s 6d to 6s 3d; fair flavour ditto 5 to 7, 6s 3d to 7s 3d; 8 to 7½, 7s to 11s; good 7½ to 8, 11s 9d to 13s 6d; fine 7½ to 9, 11s to 13s 6d per lb.—C. and G. Duggan.

THE AMSTERDAM CINCIONA AUCTIONS.

AMSTERDAM, October 14.

At today's cinchona auctions 1,000 packages Java bark were offered, of which 1,000 sold at an average net value of 40 cents per kilo, or 10s 3d per lb. being somewhat below the parity of the last London auction. The bulk of the sales consisted of Indragone, a mixture of broken quills, several being comparatively strongly represented. Dutch bark in roots and chips, received, fine 1½ to 2 cents per kilo. (=2d. to 10d. per lb.); ditto root, 20 to 28 cents per kilo. (=6½d. to 5d. per lb.); manufacturers' bark

in quills, broken quills and chips, 13 to 88 cents (=2½d to 1s 4d. per lb.); and ditto root, from 38 to 75 cents (=7d to 1s. 1½d per lb.) The principal buyers were the Amsterdam Quinine Works and the Brunswick Factory. Of the 121 tons manufacturers' bark 6½ tons contain an average of 1 to 2 per cent.; 19½ tons, 2 to 3 per cent.; 37 tons, 3 to 4 per cent.; 26 tons, 4 to 5 per cent.; 10½ tons, 5 to 6 per cent.; 15½ tons, 6 to 7 per cent.; 6½ tons, 7 to 8 per cent. quinine sulphate.—*Chemist and Druggist.*

COCONUT PLANTING NOTE.

(By an Old Planter.)

MANURING UNDER DIFFERENT SYSTEMS—PRACTICE AND THEORY.

The writer who defines manuring as restoring to the soil the elements removed from it in the crops it produces, who would regulate the supply as exactly as possible to the same quantity as has been so removed, and who objects to giving any manure whatever to the land occupied by a perennial plant till it has removed some of the natural fertility of the soil, may possibly keep up by such treatment a tolerably equal cropping from year to year, only affected by the character of the seasons. This view was set forth in the case of coconut cultivation, and really amounts to this. No matter what the quality of the soil may be, your young plant should have no assistance from manure, till after it has produced a crop, and after that, just so much as will enable it to yield another crop of precisely the same weight as the first.

There are other planters, who take a commercial view of a system of manuring: they ascertain by experiment—Newton's plan against Kepler's—the effects of a given value of manure on young, half-grown, and mature trees. If they find that 2 cents worth of manure annually will bring a young tree into flower in six years, that would without such aid have taken ten, they will be apt to hold that a gain of four years is an abundant return for 25 cents, half in manure, and half in labour. Again if they take a mature tree, that has been bearing 25 nuts per annum, and spend 25 cents in digging and manuring the land it occupies, with the result of a crop of 50 nuts in the second year after the application, and the promise of an equal return in the third, they will hardly be deterred, from playing so profitable a game by the fear of reducing the tree to a "semi-artificial existence." They will probably say that they infinitely prefer a semi-artificial tree that bears 50 nuts to an altogether natural one that bears 25. Hurrah then for the semi-artificial coconut tree!

It has been written, that, so far as the writer's knowledge goes, roots are not endowed with more than rational discrimination, but take up as much fertilizing matter as they are able to. There are plants whose chief base is potash, others whose chief base is lime, plants may be growing in soil where the base they most require is deficient, while the other is abundant, yet in no case is a plant untrue to its species, the one will not take up lime, to supply a deficiency of potash, and *vice versa*. If we deny to plants, the super-rational discrimination of selecting their specific aliments in unvarying proportions, how are we to account for those unvarying proportions and the total absence of certain elements contained in the solution, from which they derive their supplies? We must either accept this power of discrimination in the roots, or else fall back on the old theory of excremental discharges into the soil, which after all would only be transferring the discriminating power to some other organs.

Mause Headrigg held the setting-up of a winnowing machine a tempting of Providence, it being in her view a Christian duty to wait for a dispensation of wind on the sheeling hill. In like manner a Hebridean farmer called the provision of collars and traces for working cattle a setting up of carnal human inventions, in opposition to the decrees of God Almighty who had supplied the animals with sail to tie the plough to.

Those good Christians believed they were serving God in opposing with all their little might profane innovations, but there is such a thing as fanaticism outside of religious bigotry, and such is the fallacy born of presumption, and nursed in the lap of ignorance, that the young coconut plant should in no case have its growth advanced by artificial means, leave as many impediments in its way, as suits your laziness, but on no account break up the soil it occupies; on no account add the elements its constitution requires, else you will have cause to repent of meddling with nature's institution. There is no very clear explanation of the nature and extent of the calamity that will befall the rash innovator, but the rapid exhaustion and final death of his trees is clearly enough indicated. He has been told that though he himself may profit by the forcing system, his heirs will be robbed of their inheritance—a terrible calamity indeed, for the after comers, who must take realized rupees instead of the fluctuating but always diminishing income derived from a neglected coconut field. He is told that his views are impracticable by people who never tried whether they were practical or not. Of course the critic who thus denounces the unpractical theorist never heard that the same theorist took in hand a mature coconut field over twenty years old, and in ten years by annual increments raised the crop one hundred and fifty per cent; he never saw, perhaps would not believe if he did see, the result of 18 cents worth of bone dust and 9 cents of labour on a seven year old tree at the end of two years. He might see a great head of thirty green leaves, a crop of 120 nuts, and a stem running up so rapidly, that there is a space of ten feet between the lowest bunch of nuts and the highest flower, and all this before a single ripe nut has been gathered. Can the critic tell at what period the reaction is likely to set in or if there is no possible resource by which it may be averted?

The sole objective point of all agricultural operations is to get as much as possible out of the land in crops, but self-satisfied ignorance will waste labour with small effect, or if of a specially economical turn of mind he asserts that his field needs no labour, and he gives it none; that manure spoils his trees and he religiously refrains from that folly, or if he do admit that manure promotes crop, he proceeds to administer it in the most slovenly and wasteful manner that shiftless laziness ever invented. He looks moreover with the contempt of superior intelligence on the man who ventures a step beyond his own practice and if results follow that repay the expenditure four-folds, he says: "Wait and see what will happen to the trees that have been forced into unnatural productiveness." He is well assured that the day will come, and at no distant time when they will become utterly barren,—barren beyond the power of manure and manipulation to remedy. True he has not seen the end, but he has an inner consciousness, an infallible instinct, that assures him it must be so.

The innovating experimentalist will go on, endeavouring to take out of his land as much as his cultivated plant can take, and he will not confine his gratitude to restoring in another form exactly what he has taken out of the land, but will keep mending the price so long, as he finds the transaction commercially profitable, and if in the mean time he partially fails, it will be from lack of means and not from lack of will to give his trees the best chance of making an ample return.

It is a lame definition of manuring to say it is merely restoring to the land the fertilizing matter the plant has abstracted; this indeed will keep the land up to the same measure of fertility that it possessed when first taken in hand, but there is no necessity that it should stop at this point. The wheat lands of England give an average yield of 28 bushels per acre, which is more than twice as much as they yielded a hundred years ago; the increase being due to improved husbandry, and more fertilizing matter put into the soil. When coconut cultivation is better understood and more skilfully practised, a time will come,—Ceylonese conservatism, and guides with a little knowledge notwithstanding, when four candies of copra

per acre will only be considered a fair crop on average land, and no planter will hesitate to spend £10 per annum in manuring each acre of his land—net his trees. There are few among cultivated plants that yield so good a return for manure as the coconut, and one cannot begin to manure too early, except on those rare spots of rich land that bear large crops perennially, without trouble or expence.

It is not out of wanton destructiveness that we cut any of the main roots of the coconut, but our system requires a depth of nine inches for the operations of cultivation, and if any mains intrude on that space, we must of necessity dispose of them. Happily, the trees never appear to miss them, and certainly benefit more from breaking up the soil than any loss they sustain from the deprivation of a few of their worst situated roots. After all, the injury is slight, compared with digging a circular trench two feet deep at three or four feet from the stem, a practice much in vogue, among the choice spirits or our native planters. In our system the nine inches of broken soil is the proper range of the branchlets, and for them we have no tenderness whatever, assured that the more they are cut up, the often the soil is stirred, the faster they are reproduced, and the more they ramify. Those who have any doubt about this fact had better try the experiment for themselves.

Rank grass round young coconuts is very nearly as injurious as jungle, and the planter will greatly facilitate their growth by weeding a circle of four or five feet in diameter round each as often as may be required. A cooly can go over an acre daily, unless the work be all the heavier. If this work is done twice a year for the first three or four years, the grain in growth amply compensates the cost of the operation. This is over and above digging for the breaking up of the soil makes the grass grow only the quicker, and the ranker, in rainy weather. When the plants carry nine or ten leaves they are strong enough to hold their own with any merely herbaceous growth.

PLANTING IN BELL.

Plantation enterprise goes ahead along the Rokan river in northern Siak. Of late, several concessions of land have been taken out there. The banks of this river lie so high that danger from floods is out of the question. The Rokan river is shallower than the Siak river; and hence does not suit steam-boats of large draught, but it is deep enough for transport by boats and steam-launches, and thus a part of a brisk trade in rubber produce. Concessions for cultivation have been secured by Messrs. Harrison and Mader and others. Siak has only lately come to the front as a field for plantation enterprise, but prospects look so cheering that land has been eagerly taken up there.—*Strait Times*.

PLANTING IN MANILA.

The Minister for the Colonies has directed the Governor-General to do every thing in his power in furtherance of the material and moral interests of the Colony. He has been specially instructed to foster the cultivation of cotton. Specimens of Philippine cotton that had found their way to Barcelona have proved to be of excellent quality. Hopes have been in consequence aroused of rendering Spain independent of the United States in the cotton supply by encouraging cotton cultivation in these islands. The Governor-General has also been directed to push on the growing of other produce articles, such as sugar cane, hemp, coffee, and tobacco. The Governor-General has the interests of the islands at heart, and will no doubt carry the minister's wishes out so far as circumstances admit.—*Strait Times*.

WEDNESDAY, NEW GUINEA. A very interesting report of Mr Milman, Deputy Commissioner to Western New Guinea, is published in the Australian papers. He speaks of the natives as on the whole peaceable and friendly. He adds: "I was accompanied on my last visit to Mowatta by Professor Haddon, who has come out from England to report on the ethnology of our central seas. He was much interested by what he saw, and I am pleased to know that he thought highly and hopefully of the first Papuans he has seen."

TEA AT CANTON.

(Canton Circular Report for 1887.)

In tea the export is above that of last year, and it may be noticed that, although over-supply in the glutted London markets eventually brought prices down and led to heavy losses, for a time the results were very satisfactory to the exporters.

The competition of Indian, and more especially of Ceylon, tea, is felt to some extent; indeed, in Ceylon it is felt most seriously, but the art of preparing the finer-scented teas, for which Canton is noted, has not been acquired by the Indian planters, and so long as the quantity thrown on the London and the American markets is not excessive there is always a good demand there for it.

It is worthy of note, also, that it seemed the general opinion of experts, at a meeting held to discuss the question, that the quality and flavour of Canton teas has not deteriorated during the past 10 years at least, as is said to be the case at other ports; and although there has been some slight increase on the likin, the power exercised by the Tea Guild has been able to prevent its being crushed like other articles of commerce by too overwhelming taxes.

The merchants say that the extinction of the trade is merely a matter of time, and that unless the export duties and likin are very materially reduced, or abolished altogether, it cannot continue to compete with Indian and Ceylon teas; but in this I cannot agree with them. So long as the quality is maintained the taste for good teas will continue, and although the commoner sorts used only for mixing will cease to be supplied from this, there should be a good demand for the higher for many years to come.—*Hongkong Daily Press*.

NEW USES OF PETROLEUM.

Says Dr. Taylor of Science Gossip in the *Australasian*:—

A good deal of interest has been excited by the introduction of a new system of propulsion for launches, &c., introduced by Messrs. Jarrow, of Poplar. They have built a boat called the "Zephyr," which has been successfully tried on the Thames, in which volatile vapour is used instead of steam. Hitherto the application of hydrocarbon has been confined to substituting the liquid for the solid combustible material in the furnace for raising steam from water. Messrs. Jarrow's plan is to substitute spirit for water in the generator—for there is no actual boiler—using the vapour arising from it to obtain their motive power. The subject was brought before engineers last March, but it is only recently that the plan was successfully demonstrated. The material or spirit used for burning is the ordinary kerosene. The propelling machinery consists of an ordinary engine of any well-known compact type. The generator producing the vapour is placed close to the engine, and is simply a coil of copper piping into which spirit is pumped continuously by the engine. The spirit is converted into vapour on its passage through this coil, which is heated, and drives the pistons after the manner of steam. Below the vapouriser is a smaller coil, one end of which terminates in a burner, the other end being connected with an air-tight tank containing kerosene. When starting the engine, a hand air pump is used, by means of which a pressure is set up in the air-space above the mineral oil in the tank. About five pounds to the square inch is found sufficient for the purpose. In this way the liquid fuel is injected into the first box of the vapour generator. When this is ignited, and the furnace started, the heat of the flame acts on the liquid fuel before it reaches into the first box, and the oil is thus vaporized. The vapour is so mixed with common air that it is non-luminous, after the manner of a Bunsen burner. After doing its work, the vaporized kerosene is drawn away by the exhaust pipe to a condenser. Thence it is pumped in a liquid form to the tank, so that it can be used over and over again. The launches on which these experiments have been made are 36 ft. long by 6 ft. beam, made of steel. They are started within five minutes of the

word being given to light the burner. These launches will be of admirable service on small and shallow streams.

On the Thames just now may also be seen a naphtha launch, recently imported from America, in which naphtha is vapourised, and then used, as above, like steam, except that it stinks vilely. A spirit lamp supplies all the heat necessary to warm the vapouriser. The engine driving this new launch only weighs 600 lb. and is equivalent to six horse-power. The weight of the launch and engine combined is only 800 lb.

A new era is evidently dawning for petroleum. It has long been used by the Russians for motive power on their Caspian steamers, where special furnaces were devised for utilising it. In India, as well as in the United States, locomotive engines are now running which burn kerosene instead of coal, and it is said to be less costly. This is an important matter for you in Australia to consider.

THE FUTURE OF COFFEE IN CEYLON AND OTHER COUNTRIES.

Being among a group of planters and others the other day who were all more or less interested in the subject of planting either in India or Ceylon, it chanced to me to hear many opinions expressed as to the future prospects for coffee in your own island. The discussion arose out of a remark made by a Mincing Lane man, who expressed the view that a very large proportion of the coffee still received from Ceylon is fully up to the standard of quality that was so prized in former times. How is it, he asked, that this should be the case if, as is commonly said, coffee production in Ceylon is to be regarded as doomed? One would naturally expect that the continuance of long suffering due to years of leaf disease and insect attack would have resulted in a preponderance of small and ill-formed beans, but such a result does not appear to have followed. Ceylon coffee, in the matter of quality, indeed, seems to be fully up to the standard of the best days of its growth, and it was observable that the question put by the colonial broker considerably puzzled the planting experts among the listeners to his query. Of course, among these by far the larger proportion asserted that the day could never come when the growth of coffee in Ceylon could resume its old footing. They quoted the almost universal abandonment of the cultivation in order to demonstrate that the consensus of island opinion was on their side in the matter, but there were some heretics who were disinclined to pin their faith to the theory of utter extinction. One of these last seemed to me to entertain very reasonable views on the subject. He pointed out that it was the generally adopted theory that the introduction of the disease, which first struck the fatal blow at your coffee industry, had been due to the adoption of an almost single cultivation. It seemed almost, according to him, as if the leaf disease had been the result of long-continued inbreeding, a course of propagation which we know to produce evil results in all kinds of animal life. Under such conditions probably, the extinction of any cultivation would be but a matter of time. The tendency to the results of this inbreeding, it might be assumed, would be greatly checked by the extensive narrowing of the area over which it had been before exercised. Upon the remaining and greatly diminished area the effect of the introduction of new blood by an even small supply of plants from a new country, or from far-off districts, would probably be greatly restorative, and the speaker thought it extremely likely that there would be a residuum eventually left of strong and healthy trees from which a fresh life would be

widely propagated. That there must still be a large proportion of such trees left in Ceylon, he believed to be evidenced by the very fine quality of much of the coffee still received from thence in Mincing Lane. He therefore adopted the theory that, when things come to the worst, they must take a turn; that there would be a survival of the fittest, and that from these there might spring a revival of a healthy family. It was noticeable that those least inclined to accept this view were those men who had no more coffee left to indulge hope over. But even men whom I had on previous occasions heard express themselves as quite hopeless as to the extinction of leaf disease and insect pests among your coffee admitted there was something to be said on the other side of the question, and that, when coffee nearly approached extinction, the enemies of it might become wholly eradicated and leave the trees which might have survived their attack strong enough to start a healthy progeny once again. Of course it is impossible for me to judge whether there is really justification for such a hope. Probably Mr. Hughes, during his visit to you, might be able to arrive at some conclusion, as to whether the soil has become by the long continuance of a single cultivation unfit chemically for its ultimate reproduction. If he should decide otherwise, there are many of us who cannot see why coffee should not again be grown with success in Ceylon.

Now it is very certain that if this could be done, the financial result to it would probably surpass anything attained in former years by your coffee planters; because one has only to observe the records of sales in Mincing Lane to see how the little you are still able to send us is appreciated, and what competition there is for it. The increased growths in South America do not seem now able to affect the price of Ceylon coffee in the Home markets to the extent of the effect a heavy crop in the Brazils used to have on it. The reduced supply, and the difficulty consequently of obtaining the quantity demanded by the retail trade, makes your coffee less liable to fluctuation than it formerly was. I recently met a gentleman of experience, who told me that, were he now the possessor of an estate in Ceylon, he should certainly maintain a fixed amount of acreage under coffee cultivation, whether he did so at a present loss or not. He of course was one of the comparatively few men who attach weight to the theory above-named; but we find that the number of those is increasing, who believe that after a certain point has been reached coffee is likely to again show to the front in Ceylon. It is certain that the reputation of your island growth will never entirely die out in the London market, and any you can send is sure to secure buyers at top-prices. In connection with this topic I give you the following extract from *The Times* relative to coffee-growing in a country which has as yet been free from the pests which have had such a fearful result in your own case. Probably, if the lands of that country were as crowded with one form of cultivation as yours was in days gone by, they might not have escaped the result you yourselves experienced:—

“COFFEE CULTIVATION IN COSTA RICA.—The British Consul at San José, in Costa Rica, in his last report states that the cultivation of coffee is the chief and at the same time one of the most agreeable occupations of the farmer. To farm successfully in Costa Rica the land should not, on account of the high rate of interest prevailing, be purchased with borrowed capital; at least two-thirds of it should be bought by the farmer with his own capital, leaving the balance to be paid off with the crops. In this way a coffee estate will return, one year with another, 12 per cent.

on the outlay. The prices of coffee estates vary according to the quality of the land and its vicinity to the capital or provincial town. For an estate in bearing from £22 to £67 an acre may be paid. The crops are irregular, a good or large crop being generally followed by a small one, then a fair one, and then a good one again. There are two branches of the coffee industry—the first that of the simple grower, who sells the fruit straight off the trees to the cleaner and exporter. The two are often combined, but then it demands a very much larger capital to be invested in stone and brick tanks for washing, large open cemented places for drying, and machinery for removing the husk and classifying the coffee. It requires about four years before a newly-planted estate begins to bear, and as soon as the berry commences to form, plenty of rain is necessary, with moderate sunshine. Should the rains not begin soon after the blossoming of the flower, the sun scorches the young berry and kills it. Costa Rica coffee is always much appreciated in the European markets for its quality and flavour, and generally commands a high price compared with Brazilian coffee. The country, however, rarely exports more than from 10,000 to 15,000 tons per annum.

The intelligence referred to in my last letter, that there is a divergence of opinion among the members of your Planters' Association with respect to the constitution of that formed in London, has proved to be very disagreeable to several members of the latter body, who have talked over the subject with me during the last few days. I have not yet been able to see Mr. Leake, to ascertain what the points may be which it has been thought desirable in the colony to refer to London, and no one has as yet been able to inform me as to them. We had all so thoroughly made up our minds that all things were in course of thorough settlement, that to be told the contrary has not been pleasing. The conjecture has been started that a few of the members of your local body are jealous that their interests are not to be alone considered, not to receive quite undivided attention here. But the fact was, I believe, that the Planters' Association, when making its first suggestion on the subject to Mr. Leake, expressed some desire that the London Association should also be representative of the Chamber of Commerce and your Agricultural Society. If this was the case, it seems somewhat unreasonable that the fact that the representativeness of the London Committee has been given an even wider scope to, should be cavilled at. No fear need be entertained, lest other matters should have precedence of those in which your planters are immediately interested. The dealing with these last is the *rationale* of the formation of a body in London; and, as, without this as a basis, it is quite unlikely any success would have attended Mr. Leake's efforts, you may feel entire confidence that nothing would be allowed to interfere with it. However, we must leave the issue to Mr. Hamilton's able and friendly negotiation.—*London Cor.*

ELECTRICITY AND THE MORE VALUABLE METALS.

In an address at the meeting of the British Association Mr. W. H. Percey said:—Both at Swansea and Widnes immense quantities of copper, in spite of the restrictive operations of the copper syndicate, are being produced by electrolysis. Copper steam pipes for boilers are now being built up of great firmness, fine texture, and considerable strength by Mr. Elm-rod, at Cammermouth, by electro-deposition on a rotating mandrel in a tank of sulphate of copper. By this process one ton of copper requires only a little more than one ton of coal to raise the requisite steam to complete the operation. It has been shown that the electrolytic

separation of silver from gold by similar methods is perfectly practicable. The value of the material to be dealt with may be gathered from the fact, communicated to the "Gold and Silver Commission" now sitting, that nearly 90,000,000 ounces of silver are annually produced, and the greater portion of this amount contains sufficient gold to render refining remunerative. Although the old acid process of "parting" gold and silver remains practically undisturbed, there seems no reason to doubt that in the future electricity will render us good service in this direction as it has already in the purification of copper. There is not much actual progress to report in the extraction of gold from its ores by electrical agency. The conversion of gold into chloride of gold by the direct, or indirect, action of chlorine is employed on a very large scale in (Grass Valley) California and elsewhere. This fact has led to well-directed efforts to obtain by electrolytic action, chlorine which should attack finely divided gold suspended (with the crushed ore) in the solution from which the chlorine was generated, the gold, so converted into soluble chloride, then being deposited on a cathode. The process would seem to be hopeful, but is not as yet a serious rival to the ordinary chlorination method. In the amalgamation of gold ores much is expected from the possibility of keeping clean, by the aid of hydrogen set free by the electric current, the surfaces of amalgamated plates. It is well known that the late Sir W. Siemens considered that the electric arc might render good service in the fusion of metals with high melting points, and he actually succeeded in melting 96 ounces of platinum in 10 minutes with his electrical furnace. The experiments were interrupted by his untimely death, but in the hands of Messrs. Cowles the electric arc, produced by 5,000 amperes and 500 horse-power, is being employed on a very large scale for the isolation of aluminium (from corundum), which is immediately alloyed (*in situ*) with copper or iron, in the presence of which it is separated.—*Journal of the Society of Arts.*

RICE INDUSTRY OF SIAM.

Consul Child, of Bangkok, says that rice is now the great staple commodity of Siam. It has been an article of export since 1856, when the treaty with Siam, then ratified, opened up the kingdom to foreign trade. Prior to that the laws of Siam required that a three years' supply of rice should remain in the country before any was allowed to be shipped abroad. When this law was abolished a demand for rice sprang up, and the natives, learning that it was a cash commodity, commenced planting for export, and the acreage has yearly increased, thousands of Chinese engaging in the business. The demand for land has caused canals to be opened through sections which have lain fallow for centuries, and thousands of acres which were useless now stretch out for miles with fields of grain. The natives use the most primitive appliances in the cultivation of the fields, breaking up the ground with buffaloes and oxen attached to a wooden plough; but the soil is so prolific that the grain grows almost spontaneously. At times the fields require irrigation, the water being easily obtained from the rivers and canals which cross the country in every direction. As the land is level, the water rises and falls with the tide; hence the canals require no locks and are navigable for boats, which do all the carrying, since there are but few wagon roads which are traversed by buffalo carts: The rice fields are laid out in lots of about one-third of an acre each, surrounded by an embankment of earth, from eighteen inches to two feet in height, for the purpose of holding water when the land is being prepared for planting or irrigation—for which the cultivator pays a tax to the Government of a sum equivalent to about fourteen pence per field. To encourage the natives to open up new fields no tax is levied on the land the first five years. When matured, the grain is cut with sickles and stacked like wheat, and when needed is trashed by being trampled upon by buffaloes and oxen, six or eight animals being attached to a yoke, around which the straw is strewn, and over which the cattle walk round and round until the grain is separ-

ated from the straw. The straw is then piled up for the cattle, and the grain is winnowed from the chaff and dirt in a machine—a Chinese invention of a thousand years ago. The rice for export—*Kow Moong* and *Kow Soon*—is brought to the mills at Bangkok to be hulled and then packed up for export. The natives hull their rice for home consumption in wooden mortars with wooden pestles, the latter they work with their feet, though many pound it by hand. There are now fifteen steam rice mills in Bangkok, one in course of construction, and one at Patriew, a city thirty miles west of the capital. The only fuel used in these mills is the husk of the rice. There are two varieties of rice, *Na Moong*, which is sown broadcast over the fields and allowed to mature without further care and *Na Soon* or garden rice, the latter is allowed to grow to a certain height and is then transplanted. This is the rice of commerce, and is the best and highest priced of all grades. The daily consumption of rice by the average Siamese family is estimated to be from one to two English quarts.—*Journal of the Society of Arts.*

FLUSHING IN LOWER DIKOYA.

A planter writes:—"I send you by this post a couple of specimen shoots representing the sort of thing Lower Dikoya is producing at the present moment. The two shoots I send are the tipplings taken off tea two months from pruning, which had previously been plucked over once about a fortnight or three weeks ago, and these two were taken off yesterday. I weighed the shoots before doing them up, to send you, and the two weighed $\frac{3}{4}$ of an oz.; at this rate 43 shoots go to the lb.!! I should think this beats the record, don't it?" [Very likely; but we daresay Kelani Valley and Kalutara will begin to look out now for something more wonderful!]

PLANTING NOTES ON MATALE.

An old planter writing from Maskeliya says:—"I have been reading your articles on your trip with great pleasure and interest, as I know the most of the country you went over. Some of your remarks were a little out, but you are not to be blamed for that: your informants were at fault."

"Mr. George Vetch (F. H. Vetch) was not the first that purchased land in 'Dawick' Valley; there was a Captain somebody that bought a block before that, but lost it, as he only paid the 10 per cent on the sale."

"In the year 1860, 1st October, I went to the Kandy Kachechi and bought the two blocks for Vetch, 639 acres at the upset price, and it was put in to Mr. Francis H. Vetch's name, as George could not hold land, being in the Service. Wingate went with me intending to buy a block of I think 249 acres, but his heart failed him at the last moment.* You had better take a run up here and see our tea and factories; we can show something in the latter that you will remember."

CEYLON UPCOUNTRY PLANTING REPORT.

THE PROPHESED "HARD FIGHT" WHICH CEYLON WAS TO HAVE IN OUSTING CHINA TEA, AND THE REALITY—A SAMPLE OF "REALLY GOOD CHINA"—A PREJUDICED JUDGE—"WRINKLES" IN TEA MANUFACTURE.

30th Oct. 1888.

When our tea industry was young, and pushing its way to the front, wholly on the merits of the tea produced, there were not wanting those who foresaw, in our struggle to gain a footing in the world's markets, a hard fight before us, and the probability of being worsted in the end. The heathen Chinese, they said, was not easily beaten, especially in cheap working; and those who knew his capability of "living for a month on the smell of a dirty oil rag" were satisfied that the Mongolian would hold his own spite of our best

* He must have gone in soon after, and whatever Wingate owned or planted, he always had a fence of oleanders!—ED.

efforts to displace him. Very likely if we had been prosperous we would have considered a good deal more than we did, before we entered into a contest with China; but we were not, and the general blank look-out, with the growing belief, that the tea plant had found in Ceylon a congenial home, induced us to enter the lists. Perhaps too there was in some measure the courage of despair. For, as a horsey friend put it, and as indeed we all felt, we had saddled our last horse. It is now a matter of history how for the last three years Ceylon and Indian teas have, to a considerable extent, displaced the China article, and it will suit us wonderfully well to find this portion of history repeating itself.

Hearing so much of Chinese rubbish,—the stuff which is bought in bond at 4½d, and which with a pinch of Ceylon or Indian tea is considered a bargain at 1s 6d to 1s 9d a pound, and a perfectly suitable beverage for the toiling millions at home,—an old planter here, who would have nothing to do with such nastiness, sent an order to Shanghai for a half-chest of "really good China." He was curious to compare their best with ours. The half-chest came: 52 lb. in weight, and cost on the spot R95, or at the rate of R1-84 a pound! to which ere it reached Ceylon another R19-50 had to be added for freight, *octroi* charges, duty, &c. He was good enough to send on a packet of it to me, and says:—"I got down this tea, more out of curiosity than anything else, to see how the rubbish compared on the spot with ours. The comparison, I can't say I regret, has turned out odious indeed!" and these pithy words really represent how the case stands. With the exception that the tea was very fragrant—"a fine nose," I presume, is the way to put it—there was nothing to commend it. If this tea, which cost in Shanghai R1-84 a lb., is a really good China,—and at the money it ought to be,—it can only be a question of time for the complete ascendancy of the British-grown teas. It has been an old tale that it is only when in China you can get good tea, or know what good tea is. One of our merchants who had a long connection with the Empire of the Celestials was always very emphatic on this point, and to close the dispute for ever as to the inferior position our teas stood in, he agreed to get some of the really good kind sent here to him, and have his friends treated to a brew. When the trial was over, his friends were not by any means struck dumb, nor inclined to give the Ceylon article a second place; and the old China merchant had to admit that the imported article did not approach to the remembrance he had of the teas he used to drink with such relish in the land of Cathay. The fact is, he had been for some time drinking Ceylon tea; and to return from that to the wishy-washy smoky-flavoured China, was about as hopeless, as for a man who breaks away from his early faith ever to go back to the old moorings again.

Is there any secret in the manufacture of tea? Does quality wholly depend on plucking and the other etceteras which form the everyday routine of a well-worked factory? It would seem so, if what I am told be true, that R150 has been paid to the manager of Hoolankanda by a neighbour, who wants to know "how to do it." We will become a lively community by-and-by when we all take to selling our "wrinkles" for hard coin. The prospect opens a vista, in the shape of extras, which should rejoice the hearts of the theoretical as well as the practical man. The planter who works out or stumbles on a good thing will appreciate it all the more, when he finds that there is a money value attached to it. We will be having advertisements headed "The

New Tea Tip," "The Patent Packing Process," and such like. It is clear that there is more money in tea than we dreamt of, and a decline in prices may be met by a sale of "wrinkles." There is a talk of a number of estates in the Kelani Valley forming themselves into a company, so as to have all their teas cured in a central factory, and thus reducing the cost of manufacture to a minimum.

The N.-E. monsoon is no sham this year, and for a planting season nothing could be better so far. Indeed it is suiting planters generally all round, whatever their operations be, whether putting out or taking in. PEPPERCORN.

DESTRUCTION OF FISH.

Mr. H. S. Symons, of Ootacamund, has brought to the notice of Mr. H. S. Thomas, the member of the Board of Revenue in charge of Pisciculture, the wholesale destruction of fish and fry in the Bhavani river, one of the most important fish producing rivers of the Presidency. Mr. S. Symons and some friends were lately on a week's fishing on the river, and is of opinion that the district is absolutely poached out and denuded of fish and game by the Moplas. The river which formerly abounded in Mahseer weighing from 50 to 100 lb. each, is now nearly denuded of them, as only four were caught by these gentlemen in a week's fishing of the weights of 31, 10, 9 and 6 lb. The matter is to be laid before Government in order that this wastage of food-supply may be put a stop to. The Fish Preservation Act of 1879 does not affect the Mahseer as it is limited only to not-indigenous fish, and the Mahseer and its fry is consequently left to the mercy of the destructive alphas who frequent the Bhavani river and erect basket weirs at every fish-pass.—*M. Stanbury*, Oct. 21th.

DRUG TRADE REPORT.

LONDON, October 11th.

CINCHONA.—Tuesday's bark auctions were considerably smaller in extent than the preceding sales, the decrease being accounted for by the smaller supplies of South American and East Indian barks. The sales indicated—

	Packages	Packages
Ceylon bark ...	2,037	of which 1,482 were sold
East Indian bark ...	288	" 239 "
Java bark ...	156	" 156 "
South American bark	1,123	" 613 "

Total ... 3,604 " 2,490 "

The sales commenced with a decidedly weaker tone, and lower prices all round, and although gradually they improved somewhat and competition became more lively, it was evident that holders were generally much more anxious to realise than buyers were to purchase and some of the brokers simply withdrew large parcels when they saw that it would not be possible to obtain the figures at which they were listed. Taking an average of the auctions we should put the decline at fully 5 per cent. as compared with the preceding sales, and on this basis the net would be now between 14 and 24. The following are the approximate quantities purchased by each of the principal buyers:—

	Lb.
Agents for the Auerbach works ...	117,853
" Messrs. Böttger & Sons ...	107,491
" Messrs. Böttger & Sons ...	88,950
" the Brunswick works ...	67,502
Messrs. Howards & Sons ...	58,002
Agents for Jobst & Zimmer ...	20,977
Sundry buyers ...	15,765

Quantity sold ... 422,208
Brought in and withdrawn ... 263,500

Total offered ... 735,708

SOUTH AMERICAN BARK.—Calycina from the Bolivian plantations was well represented at the auction, and

a large proportion sold at 1s to 1s 1d per lb. for rich heavy silvery quill, and from 11½d down to 6d for poorer, more broken and thinner parcels; damaged bark realising from 5d to 9½d per lb. For hard Pitayo 4½d for lb. is asked. Soft Columbian, lion's head brand is held at 5½d per lb., while for an ordinary lot 2½d was refused. Cuprea, nearly all of old imper., sold well at 4d to 5½d for good sound, and 3d to 4½d for damages.

CEYLON BARK.—The assortment was a very moderate one as regards quality, and the following prices were realised: Officialis, chips, thin and mixed 3d to 4½d; good stem chips 5d to 6d; spoke shavings, fair to fine strong 4d to 7½d; root, dull dusty 4d; renewed, fair to fine rich 6½d to 1s 2d. Succirubra, dust 1½d; branch 1½d to 2d; chips, quilly and mixed 1½d to 3d; stem chips 2½d to 6d; spoke shavings, weak and dusty, mixed to fine 2½d to 5½d; root, 2d to 6½d quill, irregular and weak 4d to 5d; renewed ordinary to woody fine rich 3d to 10½d. Hybrid, &c., chips 3d to 1ld; spoke shavings 3d to 6½d; renewed 6½d to 9d.

EAST INDIAN BARK.—Succirubra, ordinary dusty root, 1½d to 3½d; fair to good spoke shavings 3d to 4½d; stem chips, fairly good bright 2½d. Ledgeriana, fine original shavings 10½d.

JAVA BARK.—Ledgeriana, good to fine rich root 7d to 9d; quilly to good rich chips 5d to 7½d. Succirubra, fair chips 5½d per lb.

QUININE has had a very uneventful week, and there does not seem to be any life whatever in the article at present. Sales of German bulk quinine, B. & S. for forward delivery (first hand), are reported at 1s 4½d and of Brunswick at 1s 4½d to 1s 1½d per oz. Other German manufacturers are practically out of the market at present. One of the German makers, however, states that most of the weak holders have cleared out, and nearly all the stock is in the hands of people more or less connected with the bark trade, who can well afford, and apparently also mean, to keep it until higher prices will rule. It is also pointed out that yellow fever in America is increasing, and that in consequence the demand for quinine in the United States has become very active. Two other facts are also noted in connection with quinine, viz., that one of the principal planters in Bolivia, who used to send over very fine bark, failed a short time ago, and that the quinine works at Bromley (England) have been closed and are offered for sale.

THE DUTCH MARKET.

AMSTERDAM, Oct. 10th.

COCA LEAVES.—With reference to recent reports about the appearance of Java coca leaves on our market, we must say that what we saw of Java produce was of poor quality, so far as the appearance was concerned, but the samples were too small for an analysis. The sample alluded to in a recent German circular did not appear in our open market. Perhaps the leaves were not properly dried before they were packed in tin-lined cases. There is no regular cultivation of coca leaves for commercial purposes in Java yet. Trials have been made, but to no extent worth mentioning.

QUININE.—At last week's cinchona auctions the quinine contained in the bark for manufacturers was sold in the following proportions:—About 1,300 kilos, sulph of quinine to the Amsterdam works; 1,250 to Messrs. C. L. Schepp & Son, of Rotterdam; 1,000 to the Brunswick works; 500 to the Frankfurt works; and the rest to seven other buyers.—*Cheest & L. Dreyfus*, Oct. 13th.

THE TEA MAKER'S SONG.

B * * *, 27th Oct. 1888.—The factory manager of the above estate begs to forward a sealed packet to the address of the Editors of the *Trop. Agriculturist*. Some time back when he crinkled, bagged, and boxed, with a weather-beaten old beam, dragged himself slowly and with difficulty up to this factory, and making various enquiries about the planters' and his friends for a *Trop. Agriculturist* bound in Calcutta, left this packet with

the request that it should not be forwarded till after his death. He offered no further explanation, except stating with an expression of bitterness, that he was a Ceylon tea-planter; and that it was not Time that had placed his withering hand on his wrinkled brow. Albeit his grey eye had no lustre in it, his cheeks were sunken and pale, and the load of three score years and ten seemed to rest on his once ample shoulders. As nothing has been heard of him since, it is to be presumed that he is dead especially as he appeared to have been on his last legs then. The packet contains, probably, his last will and testament, and the writer ventures to suggest that it had better be opened before your legal advisers in their capacity of Notaries.

THE CONTENTS OF THE PACKET:—THE SONG OF THE ROLLER-SHED (IN THE DAYS OF ROLLER-WORSHIP.)

With features haggard and worn, with eye-lids heavy and red,
planter stood at his factory door, watching his roller-shed:—

Roll, roll, roll, from muster call till dine;
And roll, roll, roll, till the hour-hand points to nine:
"Kinmond" and "Barber" and "Giant," and "Jack-son" and "Kinmond" and "Kerr."

Till over the rolls he falls asleep and dreams of the grind and the whirr.

Roll, roll, roll, from weary chime to chime,
And roll, roll, roll, to the rule of the Geppian time;
Oh men with your acres of wealth, who watch for the sale and the strife,

It is not mere souchong you grind away; but the years of your manager's life.

Roll, roll, roll, like the drums of Great Britain abroad;*

And grind, grind, grind, like the car of the Jagger-nant god:

It was oh to be a slave to the flights of a tea-taster's dream,

When you welcomed him like an inspired one, to teach you to roll and to steam.

Fire, fire, fire, when the cock is crowing aloof;
And fire, fire, fire, while the sun is hot on the roof:
Dust, and pekoe and broken, and broken, and pekoe and dust:

Roasting at once with a double fire the tea and the man to a crust.

Roll, roll, roll, while the owls are hooting aloof;
And roll, roll, roll, till the devil-bird is heard on the roof;

Roll, roll, roll, your souchong to pekoe, he says;
But roll, roll, roll, since the broker he says that you must.

So 'tis souchong and pekoe for ever and rolling and thudding till morn;

Like the strife of the surge to all time, till the blast of the last muster horn—

With features weary and worn, with eye-lids heavy and red,

A planter stood in his "planter's boots" eyeing his roller-shed;

Roll;—roll;—roll;—faintly, with tottering step,
He sang the song of the roller-shed, and expired, with
—"commend me to Gepp!"

THE GOVERNMENT GARDENS AT SAHARANPORE, INDIA.

The report on the progress and condition of the above gardens during the past official year, by the Superintendent, Mr. Gollan, is a very interesting record. These gardens are upwards of seventy years old; they are 3,000 feet in length by 2,000 feet in breadth. The receipts realized during the period under review from all sources were R14,919, being R2,119 above the estimate and R1,236 above that of the previous year. In addition to the above, seeds and plants to the value of R4,201 was issued gratis, or at reduced rates, to soldiers' and public

* Unceasing; reference to the sun never setting on our dominions which girdle the earth, &c., &c.

gardens. There has also been a saving to government of R2,315 made by the cultivation and manufacture of drugs for the medical Department. The total receipts, direct and indirect amounts to R21,435, against an expenditure of R19,327. There was more than average rainfall during the season, but irregular in its distribution. The total fall was 43.06 inches, being 9.24 inches more than the previous year, and 11.97 above the average of the ten years immediately preceding. The forest crop taken as a whole was below the average. The mango fly committed great damage. This insect is found upon the trees during summer, and lives upon the juice of the leaves, flowers, and young tender shoots, but the full extent of the mischief is done when the trees are in blossom by injuring the reproductive organs of the flowers and thus interferes with the setting of the fruit. Out of a packet of seeds of the American Dewberry, which flourishes luxuriantly in Florida, 117 plants were reared; the fruit is described as being "delicious," better than the best blackberry, and as large or larger. If it grows well in the N.-W. P., it will prove a useful addition to the varieties of upcountry fruit. In regard to date palm 101 offsets brought from the Persian gulf were planted, five died and eight are sickly, and even if all the latter die the loss will be only thirteen per cent. Dr. Bonavia, a great authority on this subject, recommends that offsets should be planted at first in shady nurseries and transplanted to the open ground after they have made some growth. But these directions were not observed at Saharanpore. The plan there adopted was to plant them at once in the open, and as it proved successful, the Superintendent recommends it to be followed with all future importations. About three-fourths of the area of five acres reserved for date planting had been taken up. The total number planted was 506, comprising 40 distinct varieties. The seeds of the Elche date palm procured from Spain being old and of bad quality were all failures. Loquats grown in the Government garden are said to be the finest in India, and as they thrive well no new varieties were introduced. The most noted variety in the list of oranges is the Sz-on-kom variety of China. Six plants were obtained from Hong-Kong and are making excellent progress. It is considered a delicacy in that country, and the finest of them are sent as a tribute to the Emperor. Plantains have not been so successful as was anticipated, the old plantations bore poor crops of fruit last season and now appear to be in need of reformation. The soil and the climate of the North are inimical to its growth.* The Burmese method of growing plantains was adopted but did not prove a success; the report says, the "advantage claimed for this method was that plantains could be grown in the same ground for unlimited periods of time without the aid of manure other than by burying all the stems which fruited from time to time in the open spaces of the plantation, and planting the young plants in the vegetable mould thus formed." It was even asserted that a plantation systematically treated in this manner for forty or fifty years would find the soil richer at the end of the periods named than before the plantation was made. This however has not proved to be anything near the truth..... "The plantation treated as above described is now only in its fourth year, but the soil seems quite exhausted and does not seem capable of rearing a single plant up to a fruit bearing stage." A collection of 23 varieties of English vines made good and healthy growth during the past summer, and nearly every plant is bearing a few bunches of fruit, the tuberous rooted Cochin China vine has not been thriving. Those kept in a heated structure passed safely through the winter, but those in the open were destroyed by the frost. In the matter of vegetables six kinds of potatoes were grown, but the outturn was much below the average owing to the frost which proved disastrous throughout the district.

* We should think so, in 30° N. L.—Ed.

Eleven varieties of watermelons were received from Florida, but the *Cuban Queen* proved the best. The heaviest individual specimen weighed 11 lb., and one plant bore five fruits aggregating 135 lb. West Indian gherkin sown in March and June germinated, but while the former did not bear any fruit the latter was quite a success. The plantation of the salt bush was very successful, nearly every seed came up with the result that 3,500 young plants are now in stock for planting out next autumn in the usar reserves. The Telf grass also gave a good return, it consists of two varieties, one with white and the other with red seeds, the former answer best for the dry season and the latter for the rains. The March sowing of the white variety gave an outturn of grain at the rate of 660 pounds per acre, and the red variety sown on the same day only yielded 17 pounds per acre. Both kinds however gave a good crop, at fodder in the middle of July, the red variety producing 11,022 and the white 7,436 pounds per acre. The hay made from the Telf was preferred by the cattle to jowar or sorghum stalks. The experiment with the *Erythroxylon Coca* was a failure not only at Saharanpore but also at Debra. The cold is too much for them, and the superintendent of the gardens thinks that it is not to be expected that the plant could be cultivated with success in the North-West Provinces. We now come to the experiments with gypsum. The ground in which these crops were grown received its full allowance of farmyard manure before being broken up by the plough, and gypsum was added in the form of a top-dressing before they germinated but before receiving their first weeding. The first six varieties of crops for the purposes of the trial were each divided into two equal plots, one on which gypsum was not applied and one on which it was applied at the rate of five manals per acre mixed with six times its weight of ashes and dry soil which was done merely to increase the bulk in order to facilitate an even distribution of gypsum over the plot so treated. The remaining ten varieties of crops were divided into three equal plots, one in which gypsum was not applied, one on which it was applied mixed with six times its weight of ashes and dry soil, and one on which it was applied mixed with six times its weight of river sand. The plots upon which the latter manure was applied gave better results than those treated with gypsum, ashes and dry soil. But there was an exception in the case of 'Landreth's' cotton, sown and with the 'white' and 'chocolate' coloured kinds. As regards the gypsum treated plot yielded more than the plots not so treated. This is attributable probably to the soil of the non-treated plot being naturally much richer than that of the plot upon which gypsum was applied. The non-treated plot of the chocolate coloured variety was 75 pounds per acre above the gypsum-treated plot, and the non-treated plot of the white variety was 180 pounds per acre above the corresponding gypsum treated plot. On the other hand in the case of beans, mung, and potatoes. One of the gypsum treated plots of beans shows an increase of 1,520 pounds per acre over the non-treated plot. Several experiments were made with the leaves of the *Pinus* trees as an insecticide. It was tried in two instances, one upon a hill and again upon the mango tree, but in both cases it failed to have any deterrent effect. Under the head of Articulture we are told that during the year under notice 1,329 plants were planted at wells, 2,414 had to be cut down as a consequence of the ill-fated monsoon hand. Among the exotic plants, the Divi-Divi suffered most from frost in the open, but better prospects exist within the garden proper, where they have been planted in ornamental groups as they have succeeded. Not a single specimen of the Mexican ebony survived the frost. The Japanese variety of tree is making very slow progress and does not give any promise of being a luminal. The *Cassia* which has failed in Saharanpore here thrives very well in Arnigadh on the hills, and proves its suitability for such a climate in India. The paper mulberry is as much

at home in the plains as in Arnigadh and was making rapid growth. Several mahogany trees were killed by the frost but those in sheltered position escaped wonderfully. There are five full-grown specimens in the garden, one of which has a circumference of nine feet at five feet from the ground. The financial results of the Mussorie gardens are as follows: the expenditure amounted to R1,703 or R1,597 below that of the preceding year. The income amounted to R561 or R65 above that of the preceding year. Fruit-trees to the value of R193 were supplied gratis to the Political Agent, Quetta, in accordance with the order of Government. The income derived being chiefly realized from the sale of fruit trees and ornamented plants.—*Indian Agriculturist*.

TOBACCO AT AMSTERDAM.—295 bales Ceylon were in store on the 1st inst. On the 9th inst, 4,854 bales Java, 295 bales Ceylon, and 269 1/2 bales Manila have been offered by tender; 4,323 bales Java, 108 bales Menado, and 501 1/2 bales Manila were bought in.—*L. & C. Express*.

CEYLON TEA IN REQUEST IN CHINA.—The following is an extract from the letter of a resident in China to a Colombo merchant:—"May I send you another order for Ceylon tea? We shall be glad to have a box of 15 lb., or, if not made up in that size, one of 20 lb. Our last was called, I think, Abbotsford, and met with great favour here."

IRON ORE IN CONGO.—It is stated that there is scarcely a country in the world so rich in iron as the Congo basin, and that the mineral is not only abundant, but can also be easily reduced. In the opinion of M. Dufont, Director of the museum of natural History of Brussels, if the other continents ever exhaust their resources of iron, the Congo basin can easily supply the rest of the world for a long period.—*Indian Agriculturist*.

FORESTRY ORATORS and theorists, say the American Cultivator—must admit after this season of unprecedented rain that the rainfall is governed by causes beyond the range and influence of forest trees and wood lots. Common sense indicates that the spongy mass of moss and fallen leaves in every forest must assist in holding moisture back, and equalizing its flow, but common folk will still fancy that the existence of large bodies of water and the evaporating power of the sun's rays have more to do with creating rainfall than the planting of forest trees or the preservation of overripe specimens of pine, spruce or hemlock, which have stopped growing and which stand in the way of the development of the younger and more vigorous forest trees.

TASMANIA is evidently destined to become one of the leading gold and silver exporting countries in the world. From a letter to the *Melbourne Age* by Mr. H. Wintle, F.L.S., we quote as follows:—

A goldfield which has so long hung over the island colony is at last beginning to be dissipated into at least a dim air in the eyes of Victoria. The discovery of metalliferous wealth made Victoria what it is at the present time; but mineral deposits are not reproductive, and latest statistics show a great falling off in the gold returns of this colony. In Tasmania we have an island whose physical structure consisted from end to end of high mountains and valleys, which bespeak, not to the geologic student, but to the most casual observer, the existence of mineral wealth which awaits capital and enterprise to extract it. The continental legislation will undoubtedly do much towards making known the earth's treasures of the island. Its great gold mine, the Loder, is located in Australia's very auriferous quartz zone, having yielded 97 tons of gold and 100,000 ounces of silver, the value of the mine of this company being at the present time over half a million sterling. This fact speaks with no uncertain sound.

QUININE PROSPECTS.—We call attention to the *Chemist & Druggist's* Drug Report on page 373, which, as usual, contains some interesting details. In respect of Quinine, especially, we are told of the failure of one Quinine manufacturing establishment at Bromley, Kent; while on the other hand it is asserted that the prevalence of yellow fever in Florida and adjacent States is creating an increased demand for Quinine. Of more interest perhaps to Cinchona planters is the news of a stoppage of planting in Bolivia.

PU-ERH TEA SEED.—A Madras Government paper gives an account of an experiment to introduce from China the seed of the specially fine variety of tea named as above. The Chinese are accused of boiling their tea seed, but there seems no necessity to assume any such practice to account for utter failure on the present occasion. The tea seed was a year old when it reached India, light and grub-eaten. Of course not a single seed germinated. Tea seed, as all planters in Ceylon know, soon loses its vitality. Rapidity of transmission is of the utmost importance, and if this can be secured and the seed packed in earth, success with the larger proportion may be relied on.

THE BLACKMAN VENTILATING CO. LTD., have received a most satisfactory letter from Captain Skinner of Silcoorie, in which he chronicles the complete success of the Blackman system of withering. It is quite on the cards that this system will be found to overcome all the withering troubles of the past, even in the worst of weathers. Indeed, from Captain Skinner's letter it would appear that it has already done so. Having gone thoroughly into this question with the Company's Manager here, the matter appears to me of sufficient importance to justify a full description, and I am therefore having an illustration prepared to accompany the description: the illustration, however, will not be ready for a couple of mails, so the matter must be postponed till then.—London letter, *L. P. Gazette*.

PARIS PHARMACEUTICAL SOCIETY.—The opening meeting after vacation having organised on Oct. 3rd with its regular officers, namely, President Delpech and Perpetual Secretary Planchon, Secretary Planchon showed a specimen of false ipeacuanha sent to him from Amsterdam. The drug in question has only the physical appearance of true ipeacac. Chemical analysis shows it to contain no emetine; and microscopical investigation proves it to possess none of the characteristics of an ipeacac. Besides, it is the rhizome of a monocotyledonous plant, while ipeacac is a root proper. Nevertheless, as it appears large quantities of the worthless stuff are brought to market under the name of Ceylon ipeacac, and its appearance is calculated to deceive, it is not amiss to give warning of the possible fraud intended.—*Chemist and Druggist*.

NORTH BORNEO TOBACCO.—Considering that the tobacco from the Ranow estate in North Borneo was dried and prepared at a bad season, and that the sorting and classification were not as well done as generally occurs on a Sumatra estate, the rate at which the 280 bales from Borneo have sold at Rotterdam must be considered as encouraging. The average price was 2s 3d per half kilo.; but some 60 bales which had not been affected by wet in the course of preparation fetched 3s 6d per half kilo. This has now definitely demonstrated that tobacco of very good quality can be grown in Borneo. Packages from Sandakan Bay and Marudu have been sold, and we are informed that a sample from Darvel Bay has been highly reported on. This means that there are three degrees of latitude on the east coast of Borneo in which tobacco can be grown, and where the rainfall—so essential to a tobacco estate—is suitable.—*L. & C. Express*.

CHINA TEA.—The *Foochow Echo* of the 15th instaut gives the following Table of Comparative Settlements in Foochow from the opening of the market to 7th September:—

SEASON 1887-1888.			
	Chests.	Half-chs.	Boxes.
Total ...	7,490	790,660	142,750
Average price per picul Taels 15.1			
Total Settlements at } Tls. 20½ and upwards }	4,506	121,040	26,330
SEASON 1888-1889.			
	Chests.	Half-chs.	Boxes.
Total ...	9,912	664,574	127,740
Average price per picul Taels 19.4			
Total Settlements at } Tls. 20½ and upwards }	9,263	242,890	83,196

—and remarks thereon in its leading columns:—
Figures are hard facts, and this table divulges a most extraordinary and deplorable state of affairs. It is simply this, that the price of tea, notwithstanding the general outcry about poorness of crop, etc., has averaged Taels 4.3 per picul more than last year, and that the merchants and speculators of Foochow have paid the teamen a no less sum than about \$1,850,000.00 more than they need have done. *Long live Foochow.*

"PEARLING" IN WESTERN AUSTRALIA.—The "pearling" referred to in the following paragraph is, of course, the collection of the large mother-o'-pearl shells:—

A deputation of gentlemen representing the pearling industry of this colony waited on the Colonial Secretary yesterday, for the purpose of pointing out to that official how pearling operations are paralysed by the heavy import and export duties at present prevailing. The deputation, which consisted of Mr. James Lilly (Manager for the Adelaide Steamship Company), Mr. D. A. Symon (Symon, Hammond & Hubble), Mr. M. Price and Mr. James Clark, was introduced by the latter gentleman, who explained how those at present engaged in pearling were handicapped, now that the market price of shell is only £90 a ton, compared with the pearl-ers of a few years ago when the ruling prices were from £250 to £300 per 'oun, and when the shell could be obtained by natives, who were employed beach-combing. Mr. Clark's remarks having been emphasised by Messrs. Lilly, Price and Symon, the Colonial Secretary expressed regret at not being in a position to furnish the deputation with a definite reply, and urged those forming it to lay their views before his Excellency the Governor, on a day to be arranged. This was agreed to, and the deputation, after having expressed their thanks, withdrew.

CEYLON AND JAVA.—A writer to the *Soerabaja Courant*, signing the initials "H. v. S.," expresses his opinion in no measured terms of the manner in which the local Government are hampering the private planting enterprise by prohibiting the employment of Chinese labor on estates, the excuse for this step being a desire to put a check on the sale of opium. The writer gives instances of the inconvenience and loss which the planters have suffered thereby, and adds:—"How different is the case in Ceylon. In the pamphlet of Mr. Mundt, 'Ceylon and Java,' it has already been pointed out forcibly what advantages the Ceylon planter enjoys over the Java one. And is the population there poorer? In Ceylon the soil is cultivated by enterprizers, not the enterprizer and population by the State, and yet there is a surplus each year. Let one just look at the map, 'Hill-country of Ceylon' (published by A. M. Ferguson, Colombo), and the districts of Matale, Dumbara, Uva and Badulla, and then everyone will understand how there enterprise after enterprize has sprung up. The Government there recognizes, that the development of colonies by the spirit of enterprize goes hand in hand with the interest of people and State." The writer points out that the very different treatment accorded to planters by the N. I. Government is driving them to settle in other countries: but he hopes for an improvement with the accession of a new Governor-General

A NOTE ON THE APPARATUS REQUIRED FOR COLLECTING INSECTS IN INDIA.

Killing bottle.—A simple and effective killing bottle is made as follows:—

Two or three lumps of cyanide of potassium, each as big as an acorn, are dropped into an empty quinine or other wide-mouthed glass bottle: enough plaster of Paris, made by mixing the dry powder with water to the consistency of cream, is poured in to cover up the lumps of cyanide. The bottle is left open for a few hours, until the plaster has set hard, when it is tightly corked up, and after remaining closed for a day or two, is ready for use.

The plaster and cyanide set into a solid mass, which sticks fast at the bottom of the bottle, the object of the plaster being to hold the cyanide in place, and the whole mass has a smooth, even surface, from which insects can be easily picked up, the glass sides of the bottle enabling the insect to be easily seen.

A few minutes in a good killing bottle, thus made, is sufficient to kill most small insects, but some of the larger species of insects require to be kept in it for several hours to insure their not reviving.

A killing bottle, when carefully used, should last for a good many months, the great thing being to keep it tightly corked up and always to close it quickly, after taking out or putting in an insect, thus allowing as little as possible of the cyanide vapour to escape.

Old quinine bottles do very well for all ordinary purposes, as killing bottles, they are cheap and of a convenient size, but are not big enough to take the largest moths and beetles, so for these a larger size of bottle should be obtained.

Killing butterflies.—All insects can be killed in a killing bottle, but for butterflies it is quite sufficient to fold the wings together over the back, and then to pinch the thorax between the finger and thumb; this kills the insect without injuring its wings.

Preserving insects in alcohol.—Eggs, pupæ and soft-bodied insects (such as caterpillars and grubs,) can be at once killed and preserved by dropping them alive into strong alcohol, where they do not putrefy or shrivel up, as they would be liable to do if they were attempted to dry them.

Small insects.—All small insects, when taken out of the killing bottle, should be at once pinned, or else gummed on to little pieces of cardboard or mica, great care being taken in gumming them not to smear the gum over their bodies; the little bits of card or mica can be pinned down into cardboard boxes, and thus closely packed to travel.

Medium-sized insects.—Medium-sized insects (including all butterflies and most moths) can be wrapped in soft paper, when they come out of the killing bottle, and as soon as they are dry, can be packed lightly but closely together into tight-fitting tin boxes, with a few lumps of camphor or naphthaline; in this way they can be sent long distances by post without fear of injury. Simply drying the packets, which contain the insects, separately in the sun and air for two or three days being quite sufficient to preserve their contents.

Large insects.—Large insects, especially those with stout abdomens, require to have the contents of the abdomen removed, and the shell stuffed with cotton wool, after which they can be dried and packed like the medium-sized insects above.

Heavy dried insects.—All insects, when thoroughly dried, can be kept in any close-fitting box or case which contains a little camphor or naphthaline. It is essential, however, for the case to be itself perfectly dry and practically air-tight.

Insect net.—A simple and serviceable net for catching insects can be made out of mosquito curtain stretched on a cane hoop with a bamboo handle attached.

Forceps.—A pair of forceps, which can generally be made locally, will always be useful for picking up small insects.

The collecting insect in determination.—In sending specimens of insect pests to entomologists for determination: each pest should be kept carefully by itself, and

when possible specimens should be sent, in all stages of development and in considerable numbers, accompanied by any notes on the habits of the insect, and a full account of the nature and extent of the damage, also any specimens (such as half eaten leaves, bored wood, damaged grain, &c.,) which throw light on the nature of the attack. Live specimens are always easier to make out than dead ones, so they should always be sent when there is a reasonable probability of their surviving the journey; chrysalides and cocoons, especially, should be sent alive, packed in a perforated box with leaves or grass. So little is at present known of Indian entomology, that the exact determination of species is often a matter of very great difficulty. Hence the necessity of furnishing full particulars and also of collecting a considerable number of specimens in each case, as these are often of great assistance in making out the affinities of an insect, and in any case form a most valuable record for comparison.

Materials.—The following materials are sufficient for collecting a vast number of insects, and would probably last one collector for at least a year.

In the absence of price list, it is impossible to say what the exact cost would be, but from Rs to 20 would probably buy all that could possibly be wanted by one collector.

For collecting ordinary dried insects the following will be sufficient:—

- Four ounces of cyanide of potassium.
- A pint bottle full of dry plaster of Paris.
- One pound of camphor (or better naphthaline).
- A couple of wide-mouthed bottles with corks.
- Three yards of mosquito net.
- A few pieces of cane and bamboo.
- Some small tin boxes.
- A packet of thin white brown paper.
- A pair of forceps.
- A needle and thread.
- A ball of string.
- A yard or two of mulmul.
- A pocket knife.

If larvæ and other soft-bodied insects are to be collected, the following should be added:—

- One quart of strong spirit (or better pure alcohol).
- Same empty bottles with corks.
- A little wax for closing bottles.

If very small insects are to be collected, the following should also be provided:—

- Two or three sheets of fine cardboard.
- Two or three packets of small pins.
- An ounce of gum arabic.
- Small cardboard boxes of various sizes.

Rough collecting.—The above list contains all that is likely to be wanted by a collector; but a great deal can be done with very much simpler materials; for instance, when other apparatus is not at hand, any insect can be killed and preserved by dropping it alive into a bottle of alcohol (or even whisky), though its colours will always be more or less damaged in the process, and it will consequently not make a good cabinet specimen afterwards.—E. C. CORZS.—*Indian Forestry.*

COFFEE PRUNING.

We have had the pleasure of reading a very interesting article in a contemporary on the subject of "Coffee Pruning." The matter is there treated in an able and exhaustive manner, and as we agree with the theories there laid down, there is but little left for us to write on the subject except to add our experience as regards the practice of different systems, which may be termed "Pruning," "light," "medium," or "heavy," and without condemning our neighbour's heavy "spur" pruning on the one side, we do not advocate the very "light" or, in some cases, total neglect of the operation by our friend, on the other. Being aware of the importance of "Pruning" as a part of the cultivation of coffee, it has received our closest attention, with a view to gain a knowledge of the actual requirements of the tree in this respect. We have watched this work more particularly in order to prune accord-

ing to the varying condition of the trees, ignoring any system of heavy cutting, such as leaving secondaries only, but endeavouring to make the most of a well-furnished tree, namely, by removing the wood that had borne in order to give place to the new. In the case of a tree having borne a heavy crop, and little or no new wood having come forward to bear foliage, the best of the old wood, with healthy leaves, should be left to provide lungs and to carry the tree on till the showers, and the exhausted wood only should be removed. This plan of pruning with a view to preserving a sufficiency of foliage has proved a very successful one, particularly during droughts. We find almost invariably that the trees carrying the greatest amount of foliage are bearing the best crop, and we think the reason is obvious. The blossom, having greater protection from the sun, is in less risk of being burnt off, and the tree being provided with ample "lungs," is enabled to absorb a sufficient amount of moisture from the dews at night. The foregoing we consider to be the "light" method of pruning, and for districts with moderate soil, elevation, &c., is probably the best for all purposes. The happy "medium" however, is only suitable to such estates as have the advantage of good soil and high cultivation, where the trees are in good order and have had careful pruning from the first. Such trees generally have more primaries, and the extent of wood to operate upon being more extended, the pruning may be made a little more severe, and the bearing wood confined to the age of two years. Next comes the "heavy" system of pruning, useful in its way, under certain circumstances of fine soil and climate, for bringing neglected trees into shape by clearing out a large accumulation of centre wood; but even here we would prefer to accomplish the object by extending the operation over a period of two or three years. The advocates of real heavy pruning, so far as we are aware, are few indeed in this district, but they, we suppose, have reason for their system of reducing the graceful form of a well-furnished tree to a skeleton, just at the hottest time of the year. Surely this excessive and sudden bleeding of the tree must prove detrimental to its vitality sooner or later, and must prejudice the production of crop. The circulation of sap being suddenly checked and confined to space causes the tree later on to force out a large quantity of "suckers," and when the early showers come, the sap runs riot and bursts out in the shape of malformed shoots that grow in every direction but the right one, and strangely opposed to the beautiful appearance of the tertiaries springing from the ripe secondaries left by the "medium" pruner, but appearances being out of the question, the "heavy" pruners assert, and very strongly too, that by confining the bearing wood to secondaries only, these are most prolific, springing as they do direct from the primary; but no amount of "handling" will prevent tertiaries from growing on the secondaries, and the tree necessarily attains a considerable amount of foliage. The system, however, of growing crop from secondaries alone spares not the tertiaries; the secondary, having borne and fulfilled its function, is cut off, and along with it the foliage of the tertiaries. On a young estate, we have found the plan of taking crop from secondaries a very good one, until the primary becomes sufficiently strong to carry tertiaries; but very few can afford to carry this system into older estates. A "bumper" crop is wanted to make up for a bad season, and then comes the necessity of pruning according to circumstances, without adhering to any special rule, except to begin and finish the work as soon as possible after picking the crop.

We trust the matter of pruning will be thoroughly ventilated. Experience teaches us that the equalizing of crops depends more on "pruning" and "handling" than any other part of the cultivation, and we consider that after giving a tree help by "manuring," the aim of the cultivation is to perfectly utilise the sap, in order to produce good and regular crops without exhausting the tree. Taken as a whole, however, we are afraid that with few exceptions too much has been expected from pruning without the aid of manure necessary to nourish the tree.—*South of India Observer.*

AMERICAN TIMBER TREES.

At the American Forest Congress, the Hon. Martin Conrad thus described the leading timber trees of the United States most useful for economical purposes, thus:—

Before I present the tabulated results of our calculation, I will give a short description of the five kinds of wood used in the construction of farm wagons, for in these five we have all the varieties that are used in implements and all outdoor machinery. I begin with the oak (*Quercus*). Of the 150 or more varieties of this tree 82 are native to this country. Of these the white oak (*Q. alba*) is the only one in demand by wagon and carriage builders, and as it is at the same time the most serviceable for all mechanical purposes, I will describe only this species. The white oak is indigenous to the State of Illinois, and is mostly found on yellow loam of moderate fertility, although it also flourishes on our prairie soil. It matures at about an average age of 80 years, after which it gains in size, but with no further improvement in quality, its further growth, being a mere accumulation of adipose, if I may use such a comparison. When fully developed the white oak is one of the largest and grandest of the entire forest tribe, and it is, of all the deciduous trees, about the most valuable for general purposes. In a wagon it furnishes the hubs, spokes, felloes and all of the running gear except the axles and the tongue, and it takes the lead in all other branches of wood manufactures where special strength, solidity and durability are required, as in ships, car-building, cabinet ware, implements, &c., &c. The natural forests of this supremely useful tree are, however, rapidly disappearing, and, if only on the ground of utility, its preservation and culture should be our very first care. Next in order comes the hickory (*Carya*). The hickory is exclusively an American tree, of many varieties, one or more of the several species being quite common in every State of the Union. None of them, however, better merits cultivation than the shellbark, for wherever special elasticity is required, as in wagon axles, carriage spoke, hammer, pick and tool handles, &c., it stands without an equal, and in its growth it is as rapid as any of its kind. The timber is heavy, hard and elastic, and is very durable, except when exposed to a foul or moist atmosphere, in which case it decays rapidly. It grows to the height of 60 or 80 feet, with a diameter of 2 feet, and while young is exceedingly graceful and ornamental, so that it might well be cultivated for its beauty alone. For fuel its wood is by far the best in America, and its fruit is the "hickory nut" of commerce. The "thick shellbark" must not be confused with the species just described. To identify the proper nut for planting I may mention that it is of a globular shape, somewhat flattened, nearly pointless, with a thin, whitish shell, and a large kernel. The nut of the "thick shellbark" is twice as large and has a sharp point at each end, the shell is thick, hard and of a yellowish tinge, while the kernel is very inferior. The leaf of the "shellbark" always consists of five leaflets, while the "thick shellbark" leaf has seven or nine. In this way the difference can be easily distinguished—not only in the seed, but in the young trees as well. Hickory for timber should be grown uninterruptedly from the seed; but it has been asserted that the transplanted tree will bear more and better quality of fruit. I will now pass on to the well-known ash (*Fraxinus*). To the manufacturer of wagons and agricultural implements this valuable timber is of high importance. It is very durable, and unites lightness, strength and elasticity to such a degree that no other wood could properly replace it for wagon tongues, fork handles and the like. It exhibits also a highly ornamental finish when used in floors, furniture, wainscoting and interior trimming of dwellings generally. Besides all this it is of high rank simply as fuel, and for all these multifarious purposes its consumption has so largely increased, that the better grades are becoming very scarce and the price has advanced at least 25 per cent. in the last 15 years. I venture to say that unless its cultivation is begun very soon, the present generation will see its last for practical uses

in this country. Indigenous to North America are the white ash, as also the "black," "blue" and "green," but of these the "white ash" is the most valuable. It bears transplanting even when quite well grown, and appears to be quite free from insect foes, so that its cultivation would have at least these important points in its favour. The next in order is the tulip tree (*Liriodendron tulipifera*), which belongs to the family of the magnolia, and although commonly known under the various names of "white wood," "yellow poplar," "tulip poplar," &c., it does not resemble the true poplar in any respect. There is but one species of this genus, and it is one of the largest and finest trees of the American forests. Hough, in his "Elements of Forestry," speaks of specimens attaining a diameter of 10 feet, and a height of 150 feet. It is found more or less all over the United States, but chiefly in the western forests wherever the climate is not too severe, and where the soil is deep and fertile. Its lumber, known as "white wood," is superior to pine in wagon and carriage building for several reasons. It is stronger, less liable to twist and warp, and has a dense grain, which renders it capable of taking a very high finish without the use of any previous "filler," for which reason also its finish is much more permanent. Its clear qualities also enable its use in wide boards and the largest class of timbers. Its quality of with being a leading attraction, it requires at least 60 years before it attains a marketable size, hence its only value to the producer in the meantime is its ornamental appearance in which it has few equals. Its leaves are large, bright and glossy, its blossoms are of good size, abundant and of an agreeable odour. This tree should be cultivated from the seed and deserves an extensive propagation, for it would be hard indeed to find another kind to fill its place in the wood-working industries, especially wagon making and furniture. Its colour and quality is decidedly affected by the nature of the soil on which it grows, and leads to the various names of "white," "blue" and "yellow" poplar, by which it is erroneously designated. The difference, however, is not externally manifest in the tree. The "yellow" variety is the toughest, hardest and most flexible, which leads to its extensive use in carriage panels, cylinder desks and other work where flexibility and toughness are required. My list of wagon woods will end with the pine (*Pinus*). This is the only coniferous tree that is of use to the wagon-maker, and it is perhaps fortunate, because none of the conifers are of any value for wagon lumber, until at least 60 years of age, being used exclusively in the form of boards. To make the best lumber, they should be thickly grown when young, in order to produce a straight tall tree of nearly uniform diameter and free from knots. If grown in isolated situations the tree will expend its vigor in the production of useless side branches, and the trunk will taper very rapidly from the base. The pine is used for wagon box bottoms, in which the "hard yellow" variety is chiefly employed. Its chief recommendation is its cheapness, since ash is fully its equal in lightness and superior in durability. The fact is, if it were possible to dispense with pine entirely, the wagon would be the gainer—and the list of our wagon woods would be reduced to the four deciduous trees already described.—*Ladies Forester*.

THE SCARCITY OF FUEL AT DARJEELING.

We reprint the following paper from the *Ladies Forester*, in view of its bearing on the state of things existing or likely to arise at our Ceylon mountain sanatorium.—[Ed.]

We publish the following letter from Mr. Prestage, dated 20th June, to the Chairman of the Darjeeling Municipality, with some comments:—

1. In continuation of my previous communication, more particularly the Darjeeling-Himalayan Railway Company's letter No. 2221 of the 27th May, 1886, to you as Chairman of the Road Cess Committee, I now have the honor to address through you the Commissioners, soliciting that urgent attention may be

given to the increased and growing cost of living in this sanatorium, and that an effort may be made to cheapen the chief supplies which are necessities to the most needy.

2. I am glad to report that arrangements have been made by which some of the largest consuming establishments will draw their chief bazaar supplies from distant, new and cheaper areas, and which will, it is thought, cause less demand on the local markets, and a consequent reduction in the cost of fowls, eggs and such produce; but I would earnestly solicit that a strong Sub-Committee of the Commissioners be appointed to consider the following, or any more workable proposals they may bring forth.

3. I have been informed by one of our late Chairmen, that since 1874 the price of firewood has increased from R15 to its present cost of R32 per 100 maunds, so that one of our main necessities has in a few years more than doubled in cost, but what is still more serious is, that from the present control and working of our sources of supply, and the neglect to produce and reproduce, there is reason to fear that another 14 years may show a further increase of cost of more than 100 per cent.

4. Interested as I am with my friends very largely in the prosperity of the district and the station, I have given special attention to the causes of the unfortunate increases in the cost of timber and firewood, and which are as under.

5. Instead of the supply of timber, as in most wood-burning countries in Europe, being under the control of the Municipality, or a body interested in giving abundant and cheap supplies, or the forests and waste areas near the stations being rendered productive or reproductive, the whole production, or rather the exhaustion of the forests, is under the control of a foreign feeble intermediate department, which fails to reproduce, and is indifferent to the increased cost of fuel and timber to the consumers.

The Remedies are—1st. I beg to urge that the supply should be as in Europe under the control of the Municipality.

2nd. The Forest Department should be deprived of all trading powers and desires, that it should only be required to produce technical advisers to Government, with instructions mainly to produce and reproduce, and not exhaust particularly near the large consuming areas.

The mode of proceeding advised is—

(a). For the Municipality (through a contractor who will be forthcoming) to re-purchase from Government the 700 acres of forest land on blocks Nos. 44 and 45 on the north of Ghoom ridge for the original purchase money R14,000, less say half the revenue the Forest Department has already netted from the blocks; it is estimated that these blocks would give a full supply to the station for the next six years.

(b). The Government to undertake to transfer to the Municipality additional areas required abutting to give a further supply for a total of 20 years, at the rate paid per acre by Government for blocks Nos. 44 and 45, viz., R20 per acre.

(c). The Government to place at the disposal of the Municipality any selected officers and employes of the Forest Department capable of reproducing and advising in forest operations to the greatest advantage.

(d). The Government to supply at actual cost seedlings and any Forest Department produce and materials required.

(e). The Municipality (through the proposed contractor) to construct or arrange to construct a good cart road or railway on the level from the 18½ mile on the Darjeeling-Himalayan Railway to the Ghoom ridge through the new unproductive lands (late Municipal blocks Nos. 44 and 45) and the Soom Tea Estate lands to the neck on the Ghoom ridge, by which a level or descending gradient would be got from the neck into Darjeeling, and the cost of hauling into the station would be much reduced.

(f). The Municipality to plant the 400 acres, now unproductive land, north of Ghoom almost abutting Darjeeling, with quick growing trees that will yield

good firewood in 20 years, and replant the areas in blocks Nos. 44 and 45 as they are exhausted, due regard to be had for preserving grazing ground for sheep and the rearing of shrubs most sustaining to cattle.

(g). The Municipality by water-power or otherwise to put up the timber to the rails from the lower levels of the blocks.

(h). The Municipality to erect such machinery as is used in Europe for the purpose of sawing up and splitting the firewood, and prevent the heavy waste of timber and labour by the present hand process.

(i). The Municipality to establish good well-covered fuel depôts abutting the railway at the junction with the Ghoom ridge new road or railway, with the Darjeeling-Himalayan main line (48½ miles), also at the foot of the Kog Jhora road and in the bazaar (Bird's godown is proposed).

6. The price to be charged by the proposed contractor for dry split firewood at the depôts is not to exceed R30 per 100 maunds.

7. I am prepared to carry through the above proposals, and will find a substantial and reliable contractor to do so if the Municipality can and will influence the Government to the extent proposed.

8. In judging of this matter, it should be kept before us that the exceptionally low and unremunerative rates at which Assam coal has been delivered in the district for the last two years failed to cause an increase in the consumption of that fuel, and I am of opinion that until a through connected line is constructed between the Northern Bengal State Railway and the Brahmaputra, that we cannot hope for a permanent supply of such fuel at sufficiently low rates to bring about increased consumption and less demand for wood fuel.

9. I have not alluded to the advantage to the station of the now large barren areas north of Ghoom ridge again being converted into forests, and of the new road or railway extension giving easy access to the virgin forests nearest to the station.

Our remarks on the above are as follows:—

Para. 2.—The arrangements referred to have made no appreciable difference so far in the cost of fowls, &c., in the local market to the general consumer. The cost rises year by year, and is likely to continue to do so as the number of Europeans in the station and at Jalapahar increases, notwithstanding the alleged improved import arrangements.

Para. 3.—The inspection of the recorded retail prices current compiled weekly in the Deputy Commissioner's office, will show that the price of firewood in the station of Darjeeling has only varied as follows in the last 14 years:—

			Seer per Rupee.	Per 100 Maunds.
June	1874	...	200 =	Rs. 20
December	1875	...	160 =	" 25
June	1876	...	200 =	" 20
June	1877	...	160 =	" 25
June	1885	}	...	120 =
June	1888			

Not exactly "more than double," as stated in the letter. This "retail" rate is, however, for small purchasers of a maund or less from retail merchants in the bazaar; the Forest Department depôt rates have been as follows for lots down to 12½ maunds since 1887, which was the first year in which the Department brought firewood into Darjeeling bazaar for sale:—

1877	R25 per 100 maunds.
1885	" 30 "
1887	" 15 ", cord.

The cord (sale by measurement of firewood stacked) was adopted in the interests of purchasers, so that the subordinates of the Department should gain no advantage as to stock in hand by wetting the wood previous to sale to make it weigh more. The cord of fresh cut wood was found to weigh about 60 maunds on the average. The rate per 100 maunds was raised to R30 in 1885 by order of Government, to allow private dealers a chance, as they complained that they could

not compete with the Departmental sales at R25; since then the Department keeps a reserve stock on hand, from which it is optional for purchasers to buy, or they can go to the general dealers; the result so far is that departmental sales have not fallen off. Private dealers now deliver on road, most convenient to purchasers' houses in carts at R30 per 100 maunds.

"Production and reproduction" in the Darjeeling forests has cost the Department as follows, as I gather from the printed reports:—

Artificial reproduction		Artificial reproduction	
R		R	
		Brought forward,	28,594
1874-75	... 5,230	1881-82,	... 4,145
1875-76	... 4,976	1882-83,	... 3,668
1876-77	... 8,577	1883-84,	... 2,856
1877-78	... 1,102	1884-85,	... 3,446
1878-79	... 4,096	1885-86,	... 2,064
1879-80	... 2,789	1886-87,	... 1,950
1880-81	... 1,824	1887-88,	... 2,425
Carried forward,	28,594	Total,	... 49,148

Or an average of R3,511 per annum, the average surplus of working these forests having been R5,382 for the same period, without allowing for share of general direction charges. The Department can hardly, under the circumstances, be fairly charged with "neglect" in this matter.

Para. 4.—The "unfortunate increases in the cost" are due primarily to the further distance fuel and timber has now to be carried, and to the increased cost of labour since the introduction of the Local Labour Act.

Para. 5.—The charges hitherto brought against the Department by the writer of the letter have been that it declines to allow the Darjeeling-Himalayan Railway to cut what trees it requires where it likes. He now accuses the Department of exhausting the forests. Had the writer of the letter had his own way, there would not be a tree fit to produce timber in the forests by this time within about 15 miles of the line of railway; he has, however, lost every case he has sent up to Government (and they are many) containing charges of obstruction and what not against the Department, notwithstanding that he dubs it (in Railway parlance?) a "foreign feeble intermediate" one.

[Which on the part of Mr. Prestage is simple impertinence, the Indian Forest Department being a most able and useful institution.—Ed. T. A.]

The Remedies.—*2nd.* I should think the writer would hardly wish Government to trust to the advice of the Department after the opinion he has given of its works above, which he there again accuses of having "exhausted" its forests.

The mode of proceeding.—(a). It would hardly need much sagacity to guess who the "contractor forthcoming" would be. These blocks 44 and 45 having been worked out by the Department as far as its "feeble" technical knowledge and management considers safe, the "contractor forthcoming" (who has presumably been interviewed by the writer of the letter) evidently makes a very sanguine estimate in expecting to get a "full supply" to the station for the next six years out of the area.

(b). There is something delightfully "childlike and bland" in this proposal. The Municipality sold Government land almost cleared of timber, and the writer of the letter wishes forest carefully conserved and almost fully stocked at the same rate from Government.

(c). Any one would think after the remarks preceding, that the "contractor" (with the help of course of the writer's experience) would be above taking advice from members of the "foreign feeble intermediate" Department.

(d). This has a decided touch of the "childlike, &c.," as at (b).

(e). The "proposed contractor" would probably profit by this very considerably. It is doubtful if any one else would benefit.

(f). The mixture of a plantation of quick growing trees "to yield good firewood in 20 years," and the use of the area at the same time for sheep grazing is quite "too too." A sight of the bare hill on which the grazing is now allowed, about three-fourths without a shrub, and about one-fourth bare rock or slips, ought surely to convince any one (the feeble intermediate Department included), that it is absurd to object to grazing anywhere, especially of course in artificially planted areas.

(g, h and i). Presumably through the "proposed contractor"?

6. The Municipality having paid the "proposed contractor" (say) from two to three lakhs for the preliminary works proposed by the writer of the letter, will of course make a handsome profit by selling at R30 per 100 maunds.

7. The "contractor" again!

8. The well-known boast of the writer of the letter about twelve months ago was that the Forest Department might shut up its depots, as before the stock of fuel then in hand was worked out nothing but coal would be used in Darjeeling and the Tea gardens along the line of railway.

9. The Municipality asked the "foreign feeble intermediate Department" to undertake the re-stocking of this area about 18 months ago, but on being informed that it must forego its grazing revenue for some years, took no further action in the matter.

The subject of fuel supplies for Nuwara Elyya, now that the railway is being extended in its neighbourhood, is well worthy of attention.—Ed. T. A.]

PLANTING IN THE LOWCOUNTRY,
WESTERN PROVINCE, CEYLON.

WELCOME RELIEF FROM THE DRY WEATHER—THE ADVANCE OF THE S.-E. MONSOON—TEA AND OTHER PRODUCTS NOT RESPONDING TO THE BESS AS HERETOFORE—MR. BLACKETT'S EXPERIMENT WITH HIS COTTON AND HIS YOUNG TEA PLANTS—THE HAMILTON CORRESPONDENT'S STATEMENT THAT A TREE NEVER OVERBEARS NOT SUPPORTED BY THE BESS'S PROFIT FROM CINNAMON VERY LOW, COMPARED WITH THE LOW PRICE FOR THE SPICE.

Siyala Korale, End of Oct. 1888.

We had a pleasant report from the dry weather, which has not entirely on all towns of cultivation I suppose, the 11th will be seen upon as the date of the advent of the S.-E. monsoon with us, if by "monsoon" is understood the rains which accompany it. The fall on the night of the 11th gauged 4 inches, but no damage was done by it, as the rain was slow and continuous. Not so with a shower which fell subsequently and which came down in bucketfuls on a soil saturated to depth. A fall of 4 inches during the space of an hour and-a-half cannot but do immense damage. While contemplating the amount of damage I was to witness the next morning, I felt thankful that my lot was not on the hills where such heavy falls do an amount of mischief that is positively heart-rending. At least such was my experience when resident on the hills. I used to waken over the damage of a rain-storm and the loss of tons of valuable soil from slips, burst drains and ever widening ravines. The rains have been so long coming that they cannot undo the mischief that has already been done. We will realize it next year in diminished crops and small sized and imperfectly formed nuts. While in former years cinnamon was the first of all cultivated products to respond to the seasonal rains, after the two severe and prolonged droughts of this year, the bushes have not made any appreciable change in their appearance till now. The soil has been so hard but that it rains but unprofitably.

Mr. Blackett's experiment with cotton has been interesting. There is no doubt an extraordinary crop, but I do not think there is much reason to apprehend that the tea plants will miss the elements of fertility removed from the soil in the cotton crop. For the first year the roots of the tea plants will not have travelled much out of the confines of the

holes they were planted in, and by the time the roots reach the ground the cotton fed on, is it unreasonable to hope that Dame Nature will have stepped in and supplied most, if not all, the constituents the cotton removed? I think it will be wise and without essential to the tea plants and the soil for the shade it will afford them, to plant cotton the first year in low clearings. Mr. Hughes ought to be able to give an authoritative opinion on the subject. It is not very clear however, how Mr. Blackett intends reducing the cotton plants, after harvesting the crop, into ashes and returning them to the soil. Where is the burning to take place? If taken out of the field, the cost will more than counter-balance the benefits of the application. Will it not be better and far cheaper to bury the bushes *in situ*? Will not the effects of the green manuring be more marked and the benefits accruing to the soil more lasting?

Your Hapitigam Korale correspondent records it as his deliberate opinion that a coconut tree never overbears. And what are the grounds for such an opinion? A tree opens 16 flowers in a year, and each flower contains on an average 20 germs. It all come to maturity each tree ought to bear 320 nuts per annum. Not one in 100,000 trees bears even 300 nuts, therefore no tree overbears. This argument carried to its logical conclusion will be, that no tree that does not mature all the flowers it produces overbears. Is this supported by the experience of anybody? What tree ever matures all the tender fruit it bears, and yet are there no instances of trees overbearing? Let us take coffee for example. During the time it was reigning monarch, instances were not rare of fields setting flowers with a promise of fruit at about a ton the acre. Tender berries were dropped subsequently calculated at over half of what came to maturity, and yet these fields were known to have been nearly snuffed outright by overbearing and had to be carefully nursed to be brought round and were for years thrown back. How is it that nature did not right itself here and take care that the shrubs did not overbear. Are we to put the plain interpretation on "I have deliberately arrived at the opinion that a coconut tree never overbears," and look upon the nut-bearing tree as an exception to the general rule? This will be rendered easy if some reasons were adduced for this. I have repeatedly seen young trees bear a heavy crop one year and take a rest the next year with a small crop, and trees that bore heavily once take many years to recover entirely.

I have heard it asked what is the value of an acre of cinnamon land at the present day with the very low price for the spice. A compact little estate very favourably situated and midway between Colombo and Negombo, and within four miles of a railway station, recently changed hands at R200 the acre. That will naturally be looked upon as the market value of cinnamon land; but this land was somewhat neglected in recent years. For land in a state of high cultivation and in a favourite locality I think R300 per acre could still be had from those on the look out for an investment. And what is the yield per acre? In the "Planting Molesworth" the yield per acre is given on the authority of two old planters at a bale of 100 lb. I have known estates yield double this, but that is exceptional. What is the income per acre? A bale of cinnamon unassorted can be had at present for about R35. Against this must be set

Superintendence per acre say	...	R10-00
Peeling per bale	...	15-00
Kaungai	...	1-00
Wedding twice a year	...	10-00
Pruning do	...	3-00
Total per bale	...	R39-00

How is cinnamon made to pay it? will be naturally asked, and how is it valued at R300 per acre when the yield per acre is R34 less than the expenditure? I will answer that presently. The figures are not mine. According to the authorities I quoted superintendence is given at 10 to 15 per acre. I made it R10. Pruning is given at 3-6. I have made it 3-3. I have taken no account of interest on capital, cost of tools, sprays of bouillies, and contingencies, &c., and yet people make a

living out of cinnamon! It is very evident that the financing of a cinnamon estate is a secret that both the "old planters" you have consulted had no intention of divulging when they supplied you the figures embodied in the "Planting Molesworth." They may look askance at me if I say that on a well-cultivated and well managed estate the yield will be more than a bale per acre and the expenditure will be less than the figures quoted, while on native gardens the working can hardly be dignified by the term cultivation, and is done mostly by the family or at cheap rates, while chips yield a few rupees the acre. Anyway the profit from a cinnamon estate in these days of low prices is cut very fine and is hardly discernible.

JAFFNA AND COTTON.

[AND TOBACCO AND PADDY.]

The people of Jaffna are not behind the age, as some persons would suppose; they are rather in advance of it, at least where money making is concerned. Look for instance at the idea of their asking for a Railway; and look at the persistency with which they press forward their petition in season and out of season. Does it look anything like the temperament of a people who are not alive to their own interests? Does it not rather prove the reverse? But if we concede anything, we concede this. They are a practical people. They look to and calculate upon results, and they would not allow themselves to be taken in by the efforts of rhetoric and the arts of the elocutionist. With the same readiness with which they rallied round the Chairman of the Railway Meeting, they have subscribed for shares in the Cotton Cultivation Company, Limited.

But the practical character of the work to be initiated will better illustrate to our readers that there need be no pessimist view taken of the project. The Directors do not contemplate to buy 2,000 or 3,000 acres of jungle or forest land in the first instance, clear it and turn it into a gigantic Estate. Such was the colossal scheme proposed by the late Jaffna and Batticaloa Commercial and Agricultural Company, Limited, whose very tremendous proportions sufficed to charm the millionaires of Colombo who would consider it rather degrading to count on a profit of 50 per cent. It perished by the colossal nature of the work it had proposed to itself.

The Cotton Company will, at the first start, acquire small parcels of land in the Tenmaradchi and Pachchimaipalli Divisions of the Peninsula, in such situations as are suited to cotton-growing, and within such easy distance as to admit of periodical inspection by one or other of the Directors. Nurseries of the several varieties of cotton will be opened, large enough to supply applicants from the villages, and leave a sufficient balance to plant model estates of the company's own with.

Tobacco-growers and cultivators of other produce who have land in reserve adjoining their gardens, will it is hoped, avail of the facilities offered by the company, to plant such reserve lands with cotton. The company will ultimately buy up all cotton, gin it here and send it to Colombo.

Nothing can be more simple, more profitable and more safe. It has nothing in it of the character of a wild or fantastic speculation, and it is hoped that the number of shares allotted to Jaffna will be speedily bought up, so that Jaffnaese outside being strengthened by the confidence of their countrymen at home may go in for the remaining shares. What has to be deplored is the loss of time. Negotiations are in a forward state of progress for the acquisition of the land, and it would be a thousand pities, if the tardiness of share holders should keep the hands of the Directors idle for another season. The iron has to be beaten when it is hot, or this splendid scheme conceived and brought forth under such exceptionally favourable auspices will languish and die; and the Jaffnaese will have to blame themselves for missing so rare an opportunity of raising their country to the level of other producing countries of the world.

At present their chief, if not only, industry resulting in an export of their produce is the Tobacco. But the world's requirements for the nasty weed cannot go on expanding indefinitely; and like the Coffee Planters, the tobacco-growers may have bitter reason to regret the folly of keeping all their eggs in one basket. If tobacco fails or the demand slackens, what is there besides for the cultivator to fall back upon? Absolutely nothing. Few are the natives who own coconut estates; and the coconut region within the Peninsula may be said to be fully occupied.

Of paddy culture in Jaffna the less said the better. It is in no sense a speculation, except that the work-a-day labourer earns his bare bread. Some few who have ancestral broad acres have the necessity laid on them to cultivate the land, if for no other reason, but to keep up the prestige of the family. But every year they sink deeper and deeper into debt until finally they quietly part, with the property to some lucky fellow who has had sudden run of wealth into his hands from tobacco or other speculation. This person takes up the cultivation in right good earnest as if he were "to the manna born," and well he may, for he has a superabundance of ready cash, which he wishes to make a show of, and he suffers besides from a craving to rank amongst the landed gentry of the country. Excepting these two classes there are few who engage in paddy cultivation as a means of making-money.

Cotton therefore comes in the very nick of time both for utilizing lands now lying waste and for affording remunerative employment of a very respectable kind to many hands now hanging idle. When Coffee failed, there would have been a complete smash of all European Enterprise, and with it a thorough destitution of all native trade, had not some far-seeing Planters introduced Tea, Cinchona, Cacao, Cardamoms, which now more than serve to uphold the credit of Ceylon in the Money Markets of Europe and America.—"Ceylon Patriot."

PLANTING NOTES FROM KEGALLA.

Tea planting by a few native gentlemen near Kegalla has taken a start. Much disappointment was felt when the small capitalists found that the so-called 5,000 acres in the Kegalla district advertised for sale consisted of isolated blocks far away and on the very confines, and even beyond the desired Kegalla district! When Sir Hercules Robinson sold over 6,000 acres in Maskeliya, he took care to see that the blocks were not only contiguous, but so cut up as to suit both large and small purses.

There is much suitable land lying between Yatideriya estate and Kegalla town owned by the Crown and Kandyans under sannases, but it is difficult to secure a block without being prepared for two years' patient work and worry. There are several very old abandoned estates bordering Dolosbage, Kadugannawa &c., but proprietors in England prefer to wait till R40 to R50 per acre is offered, as there is no more Government land available, save small chena blocks in the Kegalla, district (proper). Several native gentlemen are selecting small blocks of 30 to 50 acres to begin with, and to extend gradually by purchasing adjoining villagers' lands. The Yatideriya estate, 8 miles from Kegalla, is likely to be one of the finest in the island. It is a pity the Company is not a large one owning a few other places in this district, as there is a great future for estates here: planters pronouncing the soil more lasting than those in Kelani Valley west.

The arecanut crop is ripening now, and it is time for nurseries. It is a pity that planters do not place them closely on boundaries, as they make a good fence and give a good return on the spot by sale to natives and cost next to nothing to tend.

There has been not a sunny day since the 18th ultimo, and it is still raining; but the showers are lighter and not so heavy and "washy" as before, and paddy cultivators have commenced to level their ploughed fields and sow, but owing to the lateness of the season much inferior varieties will be sown.

PLANTING REPORTS FROM THE HILL-COUNTRY OF CEYLON :

THIS YEAR'S ABNORMAL WEATHER AND ITS EFFECTS ON TEA - CINCHONA FLOURISHING, NOW THAT THE PRICE OF BARK IS SO LOW - HIGH-GROWN TEA - DELICATE FLAVOR - PUNGENCY AND STRENGTH - HARD ROLLING - EFFECT OF LOW PRUNING - THE RAINFALL ON ABBOTSFORD.

Colombo, 5th Nov. 1888.

During my recent short visit to the hills I was too busily engaged arranging what Mr. Oliver of the railway staff affectionately termed "co-operation" as to the severance of the estate in which I am interested by the Nanuoya-Haputale extension and the passage through the land of a 6-feet bridlepath, and in other ways, to be able to deal in any detail with "the weather and the crops." My telegrams, however, embodied the great fact that better weather for both flushing and planting there could not be. So far, tea has never had such a season in our region of high altitudes in the neighbourhood of Nanuoya. The drought which in the present year followed the abnormal rainfall of the closing quarter of 1887, and which had effects so disastrous to human health and vegetable growth in parts of the lowcountry, affected us only favourably. Our porous soil, which had been thoroughly soaked by the heavy rains in the last quarter of 1887, gave back the moisture by evaporation only at the slow rate demanded by the temperature of the air at our high altitude, and the results have been "planting out" seedlings and taking in leaf, at a rate which has taxed all the powers of a large labour force. While last year was a year of disappointment, 75,000 lb. of tea only being made against an estimate of 100,000 lb., the present year promises to give fully double the result of 1887: or 150,000 lb. of made tea against an estimate of 130,000 lb. In October alone green leaf equivalent to 18,500 lb. of made tea was gathered, say 74,000 lb. of green leaf. In one day, October 23rd, the leaf taken in was 3,525 lb. the equivalent of 901 lb. of made tea, and it is probable that before now the round 1,000 lb of made tea, or 4,000 of green leaf, have been gathered in a day. Of course some portion of the increase this year on last is due to an increased area of tea coming into bearing, in our case, but the fact remains that we and our neighbours growing tea at and above 4,000 feet altitude have had one of the most favourable seasons ever experienced. What a contrast to that dreadful year, 1882, when wind-driven moisture (the moisture largely saline) threatened to destroy not merely Australian eucalypts and cinchonas but even that plant, most tenacious of life of all I know, tea. I need not point the moral: it is that oft, or even two bad seasons ought not to lead agriculturists to abate a jot of heart and hope. All will come right to him who can wait. Alas for those who could not wait. And that reminds me of the irony of fate in regard to that most disappointing "new product" cinchona. When we were getting 7s 7d per lb. for our officialis bark, the trees were cankering off in thousands. Now that 7d per lb. is probably the price likely to be realized by any we should send into the market, not a tree is sick or dying,—all, even those which were pruned until a couple of twigs at the summit only were left, are flourishing after a fashion which compels the resolve to thin them out for the sake of the tea, even in the face of prices so absurdly low as those now prevalent. It is not that the severely denuded cinchona trees have survived treatment which was intended to check their growth, but that they have put on umbrageous and horizontal growth of branches and most luxuriant foliage, which shades the more valuable tea bushes

after too dense a fashion. A considerable number, therefore, of our really fine trees of *C. officialis* are doomed, in the interests of the great staple tea. In regard to that product, what we desiderate are higher prices for leaf which, being high-grown, must be fine-flavoured,—is so, we know. But the mixers and blenders value pungency and strength, and the latter we hope to impart by harder rolling, when our second waterwheel is up, as it will be (tandem fashion) before this month is out. Without any admiration for Mr. Gepp's extravagant theories, we feel that more power for harder rolling is demanded, and perhaps more restricted withering. Meantime our 500 lb. per acre, the result of medium (not coarse) plucking, probably pay us better than if we plucked only half or one-third the quantity and realized considerably enhanced average prices per lb. We may be able some day to compare notes with estates in our immediate neighbourhood which pluck fine for tea making, and are compelled to add the plucking of *bany* (hard) leaves. I may add to my notes that the effect of low pruning (to 6 and even 4 inches from the ground) on a small field of Darjiling-China jät we have, has been marvellous in producing close expanses of plentiful flush. We have come to the conclusion that this jät of tea requires pruning once in twelve months, while the higher jät, which largely preponderate, may be plucked for 18 months, and in some cases, (dependent largely on season,) for two years.

The weather of last month and of the ten months which closed on 31st Oct., and which all through have been so favourable for tea flushing and, in the proper seasons, for planting, is indicated, as far as rainfall is concerned, by the figures in the following memorandum with which I was supplied:—

OCTOBER RAINFALL 1888—UPPER ABBOTSFORD.

Date.	Rainfall.	Date.	Rainfall.		
3rd	.04	23rd	.15	October 1888	7.25
8th	.03	24th	.10	Brought forward	74.77
10th	.04	25th	.44		—
11th	.10	26th	1.33	Total	78.12
15th	1.09	27th	.03		
16th	.07	28th	.70	Avr. for 5 yrs. Oct. 10-14	10.14
17th	.07	29th	1.21	Do 19 months 7-1885	7.38
18th	1.04	30th	.12		
19th	.37	31st	.29	Rainy days in Oct.	19
22nd	.12			Brought forward	138
Total			7.25	Total	157

Average rainy days for October (5 years) 25 2-5ths

Average total rainy days for 10 months 62 3-10ths

Jan. 1888	1.18	May	3.58	September	7.26
February	1.12	June	3.88	October	7.25
March	3.13	July	5.75		
April	6.07	August	7.11	Total	78.12

It will be seen from the figures that the rainfall for October was beautifully distributed, there being intervals of warm, calm and genial weather, rainless or only misty. All through the expired portion of the year the wind gave little cause of complaint, and, as was telegraphed, the mild wind, which has so far accompanied the north-east rains, has been hitherto from the south-west. The 7½ inches of rain in October were nearly 3 inches below the average, but a moderate fall in the north-east monsoon is, by all the laws of meteorology, to be anticipated in view of the enormous rainfall of close on 32 inches of rain in June, that excess being itself a reaction from the drought of January and February, when less than one-third of an inch fell in the two months, the first quarter of the year getting only 3.43 inches. July saw even a reaction from the rainstorms of June, when 17 inches fell in three days, but a little over 7 inches for each of th

three months, August, September, October, respectively, indicate, with mild winds and gentle temperature, most desirable weather. Similar weather to the end of the year seems probable.

HIGH ALTIITUDES AND RE-AFFORESTING—AUSTRALIAN EUCALYPTS AND ACACIAS—TOONS AND CRYPTOMERIAS—NATIVE IRON SMELTING IN FORMER DAYS AT NUWARA ELIYA.

COLOMBO, Nov. 6th.

As this matter has been delayed, I add a few words about high altitudes.

In the course of a trip to Nuwara Eliya, I noticed that several patches on the edge of the forest on the right-hand-going up, which had been largely denuded for timber and firewood purposes, had been fully cleared, doubtless by the Forest Department and evidently with a view to re-afforesting. This is a process which, I suppose, will go on. It will be interesting to notice what species of trees will be chosen to replace the natural jungle. If firewood alone is in view we have Dr. Trimen's decided opinion, founded on experience at Hakgala, that no better or quicker growing trees for the purpose can be chosen than the Australian acacias, known popularly as "watties," of which four are well established in Ceylon: *A. melanoxylon* (good for timber as well as firewood), *A. dealbata*, *A. pycnantha*, and *A. decurrens*. All these have the habit of profusely throwing up subsidiary plants from their lateral roots, the scraping away of the top soil encouraging this tendency to an extraordinary degree. A few trees can thus, in a short period, be the parents of a dense grove, which can be regularly thinned by the coppicing process. If there be any intention to grow superior timber trees, then the Australian eucalypts,—the blue and red gums, the jarrah, *E. robusta* stringy and iron barks and others included in Baron von Mueller's *Eucalyptographia* offer a wide range of choice. Again, to see the growth of a timber tree of first rate quality, common to India and Australia (the "red cedar" of Queensland and New Guinea—the *Cedrela Toona* of India), the forest officers ought to visit the really striking grove of these closely-planted, straight-stemmed, branchless trees, with their crown of luxuriant, red-coloured foliage, on a 10-acre block of land near the Lake Bund at Nuwara Eliya. This is my own experiment, and as yet it is a marvellous success, one of the trees only just over two years in the field measuring 22½ feet in height. This is at an elevation of 6,400 feet above sea-level. I mentioned on a previous occasion that at this elevation and even at 4,700 on Abbotsford, no insect has ever attacked trees which in the latter place are eight years old. The toons, too, unlike the Japan *cryptomerias* interspersed amongst them, are exempt from attacks by hares or rats, to which the tender succulent tops of the pines seem so acceptable. Dr. Trimen has expressed the apprehension that for this fine tree *Cryptomeria japonica*, the climate, with 100 inches of rain, may be found too moist. But the climate is certainly favourable to the rapid and luxuriant growth of the plants. Those not topped by animals shoot upwards beautifully, as do those which have been attacked, when they get beyond reach of their enemies. Straight and upward growth can, in the case of these pines, be encouraged by pruning off the lateral branches, by means of which the tree can be propagated. We find that the toon, also, coppices freely and can be easily reproduced by cuttings, but seed both of toon and *cryptomeria* can be so easily obtained that cuttings need not be resorted to. A few specimens of *Pinus stewartii*, obtained from the Hakgala Gardens, are also doing well in the same locality. The beautiful and fine

timbered *Pinus longifolia* of the Himalayas, I was sorry to notice, had not made equal progress; but as it has grown well at Hakgala, its comparative failure with us must be owing to causes which are capable of cure. I submit to the head of the Forest Department that *Cedrela Toona*, as one of the best possible timber trees, ought to receive special attention in the high altitudes around Nuwara Eliya where it is now pretty evident, the succulent ends of the branches are exempt from those attacks by little boring beetles which have given such a disreputable appearance to a toon I saw in the Peradeniya Gardens. But even there the stem and well-grown branches were in no ways affected. In India the tree flourishes at high altitudes: at Darjiling at 7,000 feet above sea-level, equivalent to nearly 10,000 in Ceylon; on the Dehra Doon at somewhat over 2,000 feet; but the latter altitude in about 30° north, is quite equivalent to 5,000 in Ceylon. I am not likely to forget the intense cold of a drive to and over a tea plantation on the Doon (the down place as compared with Mussooree, Landour, and the snow-covered Himalayan peaks above) in the month of February. The mention of the Doon and the recollection of its beautiful plantations of *sal* trees, leads me to ask if nothing can be done to introduce this fine timber tree, *Shorea robusta*, into Ceylon? Once, in reply to a request for seeds, we were told that the seeds of this tree cannot retain their vitality for any appreciable period, but surely they could be packed in earth, so germinating in transit? The matter cannot have escaped the attention of Dr. Trimen.

The soil in which the toons are flourishing at Nuwara Eliya is excellent,—a fact the more remarkable from the prevalence of rock fragments so rich in iron, that half-a-dozen native smelting furnaces were found on the place, one of which we have preserved as a memento of the times when the abundance and cheapness of iron and steel imported from Britain had not annihilated the native manufacture. Now that the jungle undergrowth has been cleared away, a great heap of charcoal and slag débris has been revealed, which doubtless will prove to have a manurial value. Many pieces of the slag, however, are worthy of being preserved as curiosities and ornaments. In some cases the formation is fluted with a polished and occasionally an iridescent surface. The resemblance in some instances to the products of volcanic fires is so close, that we could not wonder at the existence of pieces of the slag resulting from the old native iron-smelting furnaces being adduced to us as proof of former volcanic activity in Ceylon.

CHINA TEA has of late been so persistently run down, says the *L. & C. Express*, that it has been somewhat jocularly queried at times, "Well, is China Tea to be wiped out?" The general reply, and one in which we fully concur, is that there will always remain a demand for China Tea. It will not be as large as it has been in the past perhaps. At all events there is no prospect of such being the case for some time to come, though possibly the popular taste, aided by medical opinion, may again pronounce in its favour. There are certain qualities—not to mention aroma—in China Tea which do not exist in the importations from other countries, and as long as this remains so the demand will exist. For quality it certainly maintains its place; it is only low common grades which have given way so disastrously. Anything like wiping out China Tea is for the nonce too absurd to be seriously discussed, as it does not enter into the realm of practical politics.

Correspondence.

To the Editor.

INTERCHANGE OF PLANTS BETWEEN
JAPAN AND CEYLON.

Yokohama, 7th Sept. 1888.

DEAR SIR,—I was much interested in the remarks made by Dr. Trimmen about Japanese plants in Ceylon. It can be quite understood I think why plants from here are not likely to be suitable to Ceylon, when it is remembered that vegetation in Japan has a distinct period of rest during the dry cold winters. The climatic conditions of Japan again vary very much, more so in fact, than most countries. For the same distance in latitude you have a greater difference of temperature than can be found in most countries. This is owing to Japan's position being placed between two opposing extremes of climate, viz. that pertaining to the northern part of China, Kamschutka and Behring's Strait and the well known "Kuro Siwa" or Gulf Stream that bathes the shores of the south and south-eastern part of these islands.

It is for this reason that almost every mile of latitude combined with the distance from this warm stream has its distinct influence on the vegetation of the country. It therefore occurs that many plants that are hardy and flourish in one part of Japan will not grow in another part. This peculiar geographical position and consequent variety of climate should always be taken into account, when the hardiness or otherwise of Japanese plants is under consideration.

I see no reason however why many Japanese plants should not grow and even thrive in Ceylon, particularly those indigenous to the southern portions of these islands.

Dr. Trimmen mentions the "koya-maki" the conifer however that goes under this name is the well known umbrella pine, *Sciadopitys verticillata*. The *Podocarpus macrophylla* is the "maki" of the Japanese. I have some fine specimens of the former in my garden that are now full of cones, and shall be glad to send some of the seeds for trial. I don't think Dr. Trimmen will have any difficulty in raising plants from them.

With reference to the cycad family, the *Cycas revoluta* is perfectly hardy as far north as Yokohama. It is one of the handsomest of the group and many specimens are 20 to 30 feet high and much branched. Immense quantities have of late been shipped from the Liu Kiu Islands and Province of Kiushiu to Europe and more particularly to Germany. The Ceylon species, *C. circinalis*, is not cultivated here, even if it is known yet to the Japanese growers, but it should be as hardy as its congener. Neither the "hinoki" (*Thuja ostenii*) nor *T. pectinata* I think would thrive in tropical countries. The *Magnolia hypoleuca* that Dr. Trimmen mentions under its Japanese name of "honoki" is a deciduous species. It is very common on the hill around Yokohama; it is a very fast growing tree, and attains a height of 30 feet or more.

Has the *Cinnamomum Camphora* been tried yet in the hill districts of Ceylon?—as being the source of the camphor of commerce, it might be worth the attention of planters. It grows principally in the warmest parts of Japan, and is getting scarcer every year. I should strongly draw the attention of experimenters to this tree. The solid stearopten of the oil and known as the ordinary camphor of commerce is an article that will increase in demand, while it is now known that the oil is not that is the liquid portion of the crude camphor, consists of many valuable components that are now being used for many purposes.

S. COCKING.

[NOTE BY DR. TRIMMEN.—The camphor tree was introduced to Ceylon over 30 years ago, and grows fairly well, but the climate generally is too wet for it. *Cycas revoluta* can live anywhere, from a wet tropical garden like Peradeniya to the dry and dusty staircase of a German hotel, or the saloon of an ocean steamer. Seed of the curious and picturesque *Sciadopitys* would be very acceptable, though I fear no part of Ceylon will prove suitable for its full growth.—HENRY TRIMMEN.]

SINHALESE v. TAMIL LABOURERS ON
ESTATES; AND THE SETTLEMENT
OF SINHALESE COLONIES UNDER
RESTORED TANKS.

DEAR SIR,—The letters in your issue of the 27th on "Sinhalese labourers on plantations in the Kalutara district" are most interesting. Still more so, and more important, is the result of Mr. De Soysa's importation of Kandyan villagers to his lowcountry estate, as recorded in the same issue.

As regards the former, it seems to have been forgotten of late that the original coffee estates were all opened and cultivated with Sinhalese labourers. The objection urged against them was their proneness to return to their villages continually without due regard for their obligations to their employers. The proximity of their homes to the plantations where they worked was a great temptation to them, and their frequent absences were a serious inconvenience to their employers. Hence, when Tamils offered their services, they were eagerly taken on. Moreover, the demand for labour, which arose when the rage for coffee planting fairly set in, soon exceeded the local supply, and this went on diminishing just in proportion as the demand increased, because the money of the planters flowed amongst the villagers and made them more independent. Thus it came to pass that all the regular work of the estates, which required resident labour, fell to the Tamils, and the heavier works of felling and carting as well as the skilled work of carpentry, masonry, &c., were performed by Sinhalese, who were ever eager to undertake these more laborious pursuits.

The fact is that Tamils in their own country within reach of their own villages are even worse than the Sinhalese for running away to them from their employment on estates. Planters in S. India complain of them more bitterly than the Ceylon planters of old had reason to do of their Sinhalese coolies. Besides, Tamils are not the only race who behave better in all respects abroad than in their own country.

It is satisfactory to find that planters of today are discovering the value of the local supply of labour, and to know that henceforth the wages they pay will circulate for the good of the island, instead of being carried away to enrich the southern provinces of India.

Mr. De Soysa's splendid experiment affords reason to hope for results still more beneficial to the country, even than the employing of Sinhalese labourers on the plantations. His success shows the fallacy of the only excuse the ruling powers have ever been able to allege for not settling the people from overcrowded villages upon the lands under restored tanks. The lands so rendered cultivable at the public expense ought to be let, not sold; but the Government, whilst admitting the want of such a resource for the poor destitute villagers, always says that the people will not leave their homes! In vain is it shown that numbers of them actually do leave, and are often better off than they were, and are enabled to either to themselves or their families. In vain has it been shown, in answer to the alleged unwillingness of villagers to leave their homes, that the

terms offered by the Government are such as no man in his senses would or could accept. Even the enterprising, energetic British colonist would not go empty-handed to a strange land and settle in a wilderness, nor does he go alone. He goes in company, laden with supplies to last till his first harvests come in, and with capital or tools wherewith to house himself and comrades or family. Mr. De Soysa, wise and good man as he is, first built lines and villages to receive his immigrants, and therefore they came willingly, and soon spread the report of their newly-found homes amongst their still desolate old friends, who, in like manner, came freely to share the blessing. So, likewise, would it be on the lands under the restored tanks, if the Government were as wise and as good as their worthy exemplar, and every acre would be occupied as in the good old days.

The ostensible justification of the expending of public money on the restoration of the ancient works is to benefit the poor people who still linger upon the parched places where plenty once prevailed. Yet how is it possible for these poor parang-stricken, destitute people to buy the lands, or even to provide the scanty stock to work them, or to wait for the harvests? What mockery it is to offer the land on such terms, either to them or to their compatriots in villages whose lands have long been insufficient to support the natural increase of their population! Let the Government follow Mr. De Soysa's splendid example, and finish their work, by making the lands *tenantable*, and by offering them on terms that could be accepted. Then hundreds of villages throughout the country might have effectual relief, and thousands of villagers would have honest employment, to whom the jails now offer subsistence, diet, and homes which, miserable though they be, are immeasurably better than any others they can command. G. W.

THE EXPORT TRADE FROM THE MALABAR COAST, 1887-88: COFFEE, AND PEPPER.

Tellicherry, 24th Oct., 1888.

DEAR SIR,—We have the pleasure to hand you herewith our Annual Statement of Exports of Coffee and Pepper from the West Coast for the year ending 30th June last, which may be of interest to you. You will gather from the figures that the exports of both these products are in excess of the quantities shipped in any of the five preceding years as shown in the Statement, and we may add for ten years previous to those during which we kept statistics. The Mysore Coffee crops last year were exceptionally good, the result being that the shipments from Mangalore were very heavy, and as has been the case of late years, a considerable portion of the native coffee found its way to Tellicherry for shipment, thence to Europe: this accounts to a large extent for the imports deducted from the Tellicherry totals. Pepper is becoming more and more an important item in the exports from Malabar, and the shipments of this product is steadily increasing at Tellicherry and Cannanore, and seeing that each year is bringing a larger acreage under cultivation, there is no doubt that a bigger business in this article may be looked for.

The coming Coffee crops in both Mysore and Coorg, we anticipate, will compare unfavourably with last year: this applies more especially to estates belonging to native owners, which are not so highly cultivated as those of Europeans; but as a considerable extent of new coffee is coming into bearing, the shortage may not be so apparent as would otherwise have been the case—Yours faithfully,

p. pro. ALSTON, LOW & Co.,
RALPH TATHAM.

* Including the following:—For Genoa, 252 cwt. Tellicherry Native Coffee and 1,225 cwt. Pepper. For Bremen, 22 cwt. Calicut Plantation Coffee, 63 cwt. Native Coffee and 14 cwt. Pepper. For Hamburg, 605 cwt. Tellicherry

Native Coffee and 1,150 cwt. Pepper; 1 cwt. Calicut Plantation Coffee and 327 cwt. Pepper; 1,231 cwt. Cochin Pepper. For Anconu, 200 cwt. Tellicherry Pepper and 225 cwt. Calicut Pepper. For Malta, 85 cwt. Tellicherry Pepper. For Venice, 255 cwt. Tellicherry Native Coffee. For Suez, 903 cwt. Tellicherry Native Coffee and 543 cwt. Pepper. For Bombay and other Indian Ports, 129 cwt. Cinnamon Native Coffee and 22,323 cwt. Pepper. For Turkish, African and Arab Ports, 797 cwt. Cinnamon Pepper.

TEA ROLLERS.

Wynaad, 20th October 1888.

SIR,—Knowing you always interest yourself in all matters regarding planting and the various machinery for tea, will you kindly let me know your own as well as the neighbouring planters' opinion *re* the Kinmond-Richardson Patent Tea Rolling Machine. I have heard a lot about it, but wish to satisfy more fully before investing in one. Trusting you will excuse trouble, and oblige, as I know no one in Ceylon, having got all my experience in planting in the Wynaad.—Yours faithfully,

W. RYAN.

[The Kinmond-Richardson Tea Roller does not appear to be a great favourite in Ceylon, to judge by the few at work; but in one or two cases it has proved very useful. Mr. T. Dickson of Lebanon estate, Madulkele, likes it very much for a first roll of his tea which he finishes off afterwards in a Jackson's roller.—Ed.]

ON PLANTING: TRANSPLANTERS AND BASKETS.

DEAR SIR,—The question of how to have an estate without vacancies in it has occupied the attention of tea planters for many years, and since the days of Colonel Money's Prize E-say, various schemes have been promulgated for planting an estate, so that there may be no vacancies.

When once the tea on an estate is established and the bushes two years old and upwards, the difficulty of getting a supply to start almost amounts to impossibility by the ordinary methods.

The system of putting the seeds much wider apart in the nursery and planting with a lot of earth round the roots, has been long in vogue; in some parts of India with great success; in some cases the seeds being put in 6 inches apart each way in the nursery. In Ceylon seeds are usually planted very much closer than this from 1 1/2 to 2 1/2 inches apart, with a result of economy in nursery expenditure and a far larger percentage of vacancies in the field and consequent loss of crop.

The system of jamming plants into avanga holes and giving the coolies a large "kanak" of plants to do in a day, enables Brown to proclaim to the world that his sowing only cost R19-11 to hole and plant, "whereas Jones spent no less than R30 on his work," but a difference of 100 or more lb. an acre in crop every year will be some consolation to Jones for his spending R10 more in careful planting to begin with.

When expensive seed is being purchased my impression is, that it would pay in every case to put out plants with transplanters, or with large balls of earth on the roots. I prefer the former to the latter as (1) properly done the work is cheaper; and (2) the coolies are apt to seize the balls of earth and knock them about the roots, which throws the plants months back if the nursery soil is stiff and clayey; while if it is sandy the earth is apt to break off the plants and leave the roots as bare as if they had been hand-pulled.

As I write I have before me a piece of tea a few years old sown in 1872 was put out with a transplanter, and the plants adjoining it were larger than those put out with it, in fact it was because the plants were so tiny that it was unable to put them out in any other way that it was used and its use over the whole of the field cost the owners of expense R2-50 to R3-00 an acre.

The adjoining tea had 20 per cent of vacancies; this field with worse plants had not 2 per cent, while it has given and will continue to give far larger crops.

I planted over 250 acres in this manner during the last 18 months, and the results well justify the expenditure: one field planted with Sinhalese women at 20 cents a day and no pence money, had not 2 per cent of vacancies in it this year I believe, and the cost was only R5 an acre over 60 acres. The seed was mostly "indigenous," and cost on estate R90 a maund, giving about 10,000 plants a maund, so that the plants were worth at least R12-50 per 1,000 and more.

I do not believe that the average clearing has fewer than 20 per cent of vacancies in it; indeed 10 per cent the second year is very good.

And 10 per cent only of vacancies is 330 an acre at 12-50 per 1,000—to R4-16 saving in plants to begin with that more than repays your extra cost, and your tea comes 3 to 6 months sooner into bearing than if put in, in the ordinary way.

This is the result of my experience after having planted more than 1,000 acres in different ways.

Filling up vacancies in tea two years and upwards old, is a harder nut to crack, as the roots of the bushes already established, extract the moisture from the ground round the young plants before they are established and they droop and die after struggling on for some months, in most cases. The one successful mode that I have found of supplying vacancies, is to use supply baskets.

I have found them perfectly successful when all other plans failed, and instead of going over and over the ground year after year with most unsatisfactory results, the work can be completed at once with uniform success.

I know of one estate in Dimbula that was partly planted with them with magnificent results:—

The cost of baskets was, say	3,000		
per acre @	R5R15
Railfare say	R1 3
Extra cost of planting, say 7 per acre.

R25

Against this put the cost of 15 per cent at least			
of 3,000 indigenous plants R7-50
Coolies, supplying, &c. 2-50

Say a saving per acre ofR10-00
--------------------------	-------	----	----------

And we have got a field of tea for R15 per acre extra 6 months earlier in bearing and worth at least R100 more per acre than the adjoining tea.

With supply baskets available all over the country at R5 per 1,000 and say rail-fare R1 per 1,000, it is possible to fill up every vacancy in the country presuming them to be 10 per cent at a cost of R3 to R4 per acre and I fully believe that from the same area 10 per cent more crop would be got by so doing.

I know one man in the lowcountry who has 100,000 plants now in baskets going out, and that their use is becoming common both for tea and fuel trees, anyone would conclude from the truck loads that leave Kallutara railway station regularly "for the hills."

SUPPLY.

COTTON CULTIVATION IN CEYLON.

DEAR SIR,—With reference to cotton cultivation in Ceylon, perhaps the following may interest your readers. Last June I received a small bag of Indian cotton seed from Mr. Mitchell, and on the 22nd and 23rd of that month I roughly dibbled it out in rows in a new chena clearing on Crystal Hill estate. The month of June was showery, but since the planting there has been no rain to speak of to date; in fact as you are aware there has been a hard drought. Beyond two rough weedings, it received no further care or attention. Within two months from sowing it began to bud freely; for some time back the plants have been covered with blossoms, and now (this 2nd October) say some fourteen weeks after sowing, an open boll of ripe cotton has been found. The pod is very small; but whether this is due to the drought or the kind of cotton I can't say. Anyway the time required for the cultivation seems exactly to suit the north-east monsoon in this part of the country.—Yours truly,

A. G. K. BORRON

CHINA AND JAPAN TEA EXPORTS FOR 1888-89 : TOTAL SUPPLY FOR UNITED KINGDOM.

As three-fourths of the current season's supply from China for Great Britain has now been shipped, the interest in the export returns has so diminished as to render it unnecessary for us to incur the expense of having the fortnightly figures telegraphed to us from the Far East, for the information of our planting subscribers. We have therefore discontinued these telegrams; but we shall resume them when next season's supply becomes one of interest to our readers. In the meantime, in order to keep our tea-planting friends in touch with a subject of so much importance to them, we will occasionally publish comparative returns as we did before we commenced the special messages. Our readers will see that to provide for deliveries of 220 millions of pounds in Great Britain, the estimated quantity required between the 1st June 1888 and the 31st May 1889, the probable receipts were given by Messrs. Stenning, Inskipp & Co. at 221 million lb. They put forward in June last, the following figures:—

Probable Tea Shipments to the United Kingdom :

China and Japan	100,000,000 lb.
India	93,000,000 "
Ceylon	25,000,000 "
Java	3,000,000 "

Together 221,000,000 lb.

It was evident, therefore, that the supply to Great Britain and the deliveries for consumption and export were so nearly equal, that there were good grounds for anticipating a healthy state of the Tea Trade until the prospect of the supplies for 1889-90 had to be dealt with, provided the figures for this season's supply were not under-estimated.

As three-fourths of the China and Indian supply for the current season have now been shipped, we are in a position to form a tolerably correct opinion on the above estimates put forth at the commencement of the tea year. By the subjoined figures it will be seen that the China and Japan exports to the 20th March amounted to 75,359,963 lb., against 90,676,023 lb. last year:—

Exports from China and Japan to	United Kingdom for...	1888-9	75,359,963
"	"	1887-8	90,676,023
"	"	1886-7	120,088,784
"	to America for...	1888-9	42,304,225
"	"	1887-8	37,786,845
"	"	1886-7	47,988,874
"	to Australia for...	1888-9	21,859,531
"	"	1887-8	20,516,371
"	"	1886-7	18,627,307
"	to Continent almost entirely to Russia...	1888-9	18,070,667
"	"	1887-8	12,820,667

To make up Messrs. Stenning, Inskipp & Co.'s estimate of 100 million lb. 24½ millions of lb. only should be shipped during the remainder of the season to the United Kingdom. Last year between the 20th October and the end of the season 32½ millions of pounds were shipped. The question therefore is, as regards the China and Japan supply, what is the prospect of the remainder of this season's export being 8 millions of pounds below last year's figures? Taking into consideration the advanced period of the year, and the stocks in the chief treaty ports, we are inclined to think that the China supply will be from 3 to 5 per cent over the estimate, but 13 to 20 millions below the total of last season. The great falling-off so far this year has been in the Poochow supply: the decrease has been 1½ millions of pounds. From the Yangtse ports it has only been 1½ million, and from

Canton and Macao 2½. There is little doubt, but that there will be a further considerable decrease from the Yangtse ports, as the stock at Shanghai is only half of what it was this time last year. The supply from Canton and Macao is dwindling down into very small figures, and the quality of what is now coming to market is of the lowest possible description. The arrivals at Poochow have as usual at this time of the year become small; but, as the stock there is 30 per cent more than last year, namely 10 million pounds against 8 millions, there may be some increase from that port. A careful comparison of the figures induces us to think that the total supply from China will be under 105 million of pounds.

From India up to the 1st instant to the United Kingdom, 57 million lb. have been shipped out of an estimated supply of 93 million pounds. Judging from the tenor of the Indian advices we should say that the full quantity estimated will not be shipped to the United Kingdom from Calcutta,—the increase will probably be this season 8 millions of pounds against an estimated increase of 10 millions. The only doubtful element, then, in the calculated supply is that from Ceylon. The export from the 15th of April to the end of October, or 6½ months, has been 14 million lb., out of an estimated supply of 25 millions for the year ending 31st May 1889. There is thus 11 million lb. to be shipped between the 1st Nov. and 15th April next. The question is, will it be more or less? Our own idea is that the quantity will be about 13 million pounds, against Messrs. Stenning, Inskipp & Co.'s estimate of 11, showing an increase which exactly balances the estimated decrease in the case of Indian exports. The estimated supply from Java to the United Kingdom may be taken at from three to four million lb.

Looking at these figures as a whole, therefore, there is nothing to indicate an oversupply of our staple to the 31st May next, and therefore no occasion to anticipate otherwise than a firm market and good prices, save from any passing fluctuation due to temporary causes.

CEYLON TEA AND COPYING OF ESTATES' NAMES.

The lessee of Taprobana estate, Dimbula, has just had a curious experience. His London Agents, in reporting a sale of his tea (9th October) as follows:—

Marks.	Packages.	Goods.	Price per lb
Taprobana	16 half chts.	Pekoe	1s
	8 "	Broken Pekoe	1s 6½d.
	10 "	Orange "	1s ld.

34

add in their letter:—

"You will be interested in seeing the enclosed wrapper which covers packets of tea sold by a tradesman in the Borough. We have brought and tasted the tea which is fairly good, but as the man sells it at 1s 10d per lb. we expect there is cheap China mixed up with the Ceylon, but it is difficult to detect it." The label enclosed is a bright yellow one, and runs as follows:—

"Rich Ceylon tea,—Taprobana,—Harrington and Lucas, Tea and Coffee Merchants, 155, Borough High Street, London, S. E.

11d per half lb.
This delightful tea surpasses in excellence the growth of China or India: it is absolutely pure and unmixed combining the delicate flavour of the finest China teas, with the strength and fragrance of fine Indian. This tea is peculiarly adapted for the dyspeptic and for invalids, being free from excessive astringency and tannin. To be had only of Harrington and Lucas, 155, Borough High Street, London, S. E."

Of course Mr. Morrison had never heard of Messrs. Harrison & Lucas before, and for them to say that "Taprobana" tea is only to be had from them and to sell it at a rate which inevitably means "mixing China" is rather too much. Of course they will say that "Taprobana" is used as another name for Ceylon; but, as regards the "pure Ceylon" tea, Mr. Morrison's Agents should not let the matter drop, but communicate with Mr. Leake and see whether a test case cannot be tried.

TEA IN AUSTRALIA.

I quote the following from a private letter just received from a friend settled in New South Wales:—"You are quite right about the people having chiefly the cheap rubbish from China; the general quality which I meet within my travels is innocent of the slightest flavor of the leaf, and it has always been a marvel to me that rich men, big squatters, bankers and prosperous hotel-keepers will buy such fearful stuff. Yet I am doubtful of any success in introducing your tea, simply because habit has so overcome any antipathy. This is a town of 1,300 inhabitants, and a centre of supplies for at least 4,000 square miles, and there are some 3 or 4 large stores where tea is sold. I am afraid the price would be a little too high for general consumption, because tea which is consumed on runs and large farms is bought wholesale, and sold in small quantities to the hands on the run, who will not give a high price, although they could afford it. I have spoken to the principal storekeeper here, and he says that the only persons who could introduce it would be the large merchants in Sydney. Tea (so called) is drunk here at every meal. Wine, spirits and beer are taken between meals."—*Cor.*

THE NEW BRITISH PROTECTORATES IN THE PACIFIC.

It was recently announced from Auckland that the acting British Vice-Consul at Rarotonga had been instructed to proclaim a British protectorate over the Cook Islands. The proclamation is to be made on the 20th inst. at Rarotonga, and as soon afterwards as may be possible at the remaining islands of the group. News has since been received to the effect that Savage Island is also to be proclaimed a British protectorate. The accompanying chart shows the position of all the new protectorates. They are situated, as will be seen, between the Friendly Islands of Tongas, an independent group, and the Society Islands, which belong to France. To the north-west the nearest islands are the Samoan group, or Navigator's Islands, where German influence is practically paramount. To the south-west, the only islands between the Cook group and New Zealand are the Kermadecs, which were annexed by us in 1886.

Cook Islands were discovered by Captain Cook, and have since been visited by, among others, Captain R. D. Bethune, of Her Majesty's ship "Conway," in 1837; Captain T. Harvey, of Her Majesty's ship "Havana," in 1857; Lieutenant A. Quentin of the French ship "L'Archeche Treville," in 1861; and Captain K. H. A. Mainwaring, of Her Majesty's ship "Camelion," in 1872. The group consists of the Islands of Rarotonga, Mangaia, Takutea, Atiu, Mitero, Mauki, Aitutaki, and the Hervey Islands, and consists of one or two other islands the names of which are not known. Rarotonga, the largest and one of the most fertile islands, is intimately associated with that of the missionary John Williams, in a beautiful island, on the eastern coast, the central portion having an elevation of 2,000 ft. It is about thirty miles in circumference,

and is surrounded by a reef, but there is no anchorage. Small craft may, however, lie within the reef off Avarua, which is the chief village in the place. The other villages are Atania, Ngatangia, and Arognani. The total population is now about 3,500 souls; but in 1837 it was said to be 7,000. Cotton, coffee, and fruit are cultivated with great success. The island has hitherto been under the rule of an independent queen. Mangaia, or Mangea, is of about the same size as Rarotonga, and is also volcanic. Its highest summit does not nevertheless exceed 700 ft., and it is, upon the whole, rather flat. There are neither reefs nor anchorage, the surrounding sea being extraordinarily deep. The principal village, Oneroa, lies on the west. The island has hitherto been governed by an independent king. As for the population, it was once fully 5,000, but is now not more than 2,000. Takutea, Atiu, and Mitero form a confederation of petty kingdoms. Takutea, or Wenua-iti, is but three miles in circuit and has a very small population. Atiu, otherwise Vatiu or Wateo, is twenty miles in circumference, and the population numbers about 1,400. Mitero is some sixteen miles in circuit, and supports 250 souls. Mauki, or Parry Island, is only two miles in diameter and is very low. The population does not exceed 300. Aitutaki was discovered by Bligh in 1793. It is rather flat, about eighteen miles in circuit, and dangerous to approach. It is governed by three chiefs, whose subjects number nearly 1,700. There is a jetty, but only small craft can lie alongside.

Savage Island, which was discovered by Cook in 1774, and so named by him on account of the ferocious reception which he met with at the hands of the inhabitants, is properly called Nieuve, or Innie, or Felekaho. Its inhabitants, some 5,500 in number, are of a different race from those of the Cook Islands, and resemble rather the Samoans. Cook seems to have been the only person who found them savage. Captain Erskine, R.N., in 1849 found them perfectly trustful and harmless. They are, moreover, very industrious, and according to Mainwaring, have never been cannibals. The island, which is thirty-three miles in circuit, is low and of coral formation. Of late years it has been a favourite resort for German traders; and the Messrs. Godeffroi, of Hamburg, established an agency there early in their business career. This fact is, no doubt, sufficient reason for the protest which Germany makes against the proclamation of the British protectorate. In none of the Islands does there appear to be any harbour of sufficient size to admit even a small man-of-war; but was watering places, and perhaps as coaling stations on a small scale, the new dependencies may be useful when the opening of the Panama Canal creates a new route between England and New South Wales.—*St. James's Budget.*

DRUG TRADE REPORT.

LONDON, October 18th.

CARDAMOMS.—At today's auctions only 88 packages were offered for sale, and the bulk of this sold at a sharp advance, medium qualities occasionally at 3d to 4d beyond the variations, but not quite so much higher for the best lots. Ceylon Malbars, good medium yellow 1s 0d to 1s 10d; small 1s 8d; medium to small lacy-capped and dull 1s 4d to 1s 5d per lb.; small and brown lacy-capped and lacy 5d per lb. Mysore, medium to good smooth berry long 2s 3d to 2s 4d; small 1s 8d; long fair small to medium 1s 6d to 1s 5d; yellow speckled and split 1s 4d. Peppercorn good pale 1s 7d; fine old brown 1s 5d; ordinary brown 1s 4d; seed 1s 3d to 1s 2d per lb. The following figures refer to the exports from Ceylon in the period between October 1st and September 25th.

1887-8, 303,063 lb.; 1886-7 310,859 lb.; 1885-6, 230,804 lb. A planter at Haputale (Ceylon) writes as follows:—"Cardamoms have benefited by the long drought, as the sun penetrated to the very roots, and has brought out excellent blossoms; the coming crop should be a good one; pity the market for this product is so ridiculously low, the prices realised barely pay for gathering and curing."

CINCHONA.—The South American barks offered today realised exceptionally high prices; Guayaquil, fair to fine bright silvery quill, 1s 9d to 2s 5d; good thin brownish Huanoco, 1s 2d to 1s 4d; stout brown and damaged from 4½d to 8d per lb. Flat Calisaya, hard medium to bold good bright, 1s 11d to 2s; thinner, 1s 9d; damages, 1s 3d to 1s 10d per lb. The following are the exports of bark from private plantations in Java during the first six months of 1886, 1887, and 1888, as given in Government statistics:—

	1886. kilos.	1887. kilos.	1888. kilos.
To Holland	341,587	234,704	575,552
To United Kingdom	80,794	40,036	62,842
Total	422,381	274,740	638,394

CROTON SEED.—Ten bags Ceylon seed sold at 15s 6d per cwt.

OIL (EUCALYPTUS).—The 3 cases Spanish Eucalyptus oil offered at the last drug sales have been sold at 1s. 10½d. per lb. With regard to this oil we understand that it was distilled in Valencia by a grower there as an experiment, but the price obtained not yielding sufficient inducement, the grower will not, at present, continue to make it, and means to cut down a greater part of his trees next month to sell the wood. The 3 cases referred to were accumulated stock of several years, about 168 kilos. altogether. Fresh oil, if distilled, would cost about 4s. 6d. per lb. f. o. b. Valencia.

OIL (PALM) is now firmly held at £24 to £24 10s. for fine Lagos, but this fresh advance has checked business to a great extent. Our stock has been reduced to a minimum.

QUININE is again lower. Sales of some importance are reported during the week at 1s 4d for forward delivery of German bulk quinine to strong buyers in Mincing Lane; and it is said that 5,000 oz. B. & S. quinine have changed hands at 1s 3½d, cash in second hand. The quotations are now as follows:—Howard's bulk, 1s 7d to 1s 8½; bottles, 1s 9d to 1s 10½; Whiffen's bulk, 1s 5½d; Pelletier's bottles, 1s 10d; Fabricca Lombarda, 1s 5d; Zimmer and Jobst, 1s 5½d; Auerbach, 1s 5d; B. & S. and Brunswick, 1s 4d per oz., all bulk. It is remarkable that at the same time that a firm of German manufacturers issued a circular in Europe calling attention to the increase in the consumption of quinine in America, owing to the ravages of the yellow fever in the Southern States, the New York agent of one of the German makers circularised the trade in America with the statement that "the stir caused in Europe through the report of fever in the unfortunate South has no justification, as the dreaded scourge there is unaccountable by quinine."

Messrs. Oscar Andrae & Co. desire us to say that the quantity of cinchona bark bought by them for the Auerbach quinine works in the auction of October 9th was 146,638 lb.—*Chemist and Druggist.*

RICE.—According to the first reports of the season, the area under rice cultivation in the ten chief rice-producing districts in Burma this year is 3,603,932 acres as compared with 3,475,567 acres, the actual area of last year, the increase being 128,415 acres.—*M. Mail, Nov. 3rd.*

COFFEE can hardly be a very common surname and Ellen Coffees must be still more rare. It is all the more remarkable, therefore, that at Bow-street Police-court one Ellen Coffee should have been convicted of assaulting another Ellen Coffee—prisoner and prosecutrix not being related to one another.—*L. & C. Express.*

TEA.—The following appeared in the London *Times* of Friday last:—For sale, an Indian Tea Garden, has averaged dividends for the last three years of 8½ per cent, after allowing £450 a year for management Books may be examined by any firm of accountants Price £5,000. Write Teaplant, May's Advertising offices, 162, Piccadilly, W.—*Home and Colonial Mail, October 28th.*

THE INTRODUCTION OF COFFEE INTO JAVA PROHIBITED.—We have received a copy of a circular in French issued last month by Dr. Treub, Director of the Government Botanic Garden, Buitenzorg, Java, to the following effect:—"The introduction of seeds and plants of coffee and other tropical Rubiaceae having been prohibited pending further orders into Netherlands India, correspondents of the Buitenzorg Botanic Garden are earnestly requested not to send to this establishment either seeds or plants of the abovementioned trees."

COMPRESSED FUEL.—An anxious problem with coal merchants in London and the provinces, as well as upon the seaboard, has long been that of the disposal of the dust or slack from their coal, which in some cases has accumulated to the extent of several hundred tons and is still accumulating. Attempts have been made from time to time to solve this problem, but without any apparent practical success. Now, however, there appears to be a reasonable chance of the question being settled in a satisfactory manner by the aid of a briquette making machine which has been invented by Mr. Mowll and Mr. Messenger, C. E., of Dover. There are already several machines extant for making patent fuel bricks for steam purposes, but among other drawbacks incident to them, the machines are too large and costly for use by coal merchants, while they produce blocks of fuel which are much too large for use by the public in general. The new machine which we recently saw in operation at Creek-bridge Wharf, Greenwich, is of comparatively small size, and the briquettes made by it measure only 4½ in. long by 2½ in. wide and 2½ in. deep, and weigh 1½ lb. each. In making these briquettes the coal dust is first mixed with 10 per cent. of crushed pitch, and the mixture is fed into a vertical mill in which the ingredients are thoroughly incorporated by stirrers. At the bottom of the mill the ingredients encounter a jet of steam which melts the pitch and brings the mixture into a plastic condition. The mixture is then fed into a revolving mould and the charge receives its initial pressure from a horizontal plunger. The mould then makes a partial turn and the partially compressed charge encounters another plunger which gives it the final pressure. Another partial turn brings the compressed charge to an ejector which pushes it out of the mould into a trough, from which the briquettes are removed by a boy on to a tray to be taken away for stacking. The briquettes are ready for use in about an hour from the time they have been delivered from the press. The action of the machine is continuous, the operations of moulding, pressing, and ejecting being carried on simultaneously by means of the rotary mould block. The rate of ordinary working is about 14 briquettes per minute, or five tons per day of 12 hours, which can be increased to six tons if necessary by working at a higher speed. The machine can be erected at a comparatively small cost, and can be worked by unskilled labour. It can be driven either by horse or steam power, so that its services are available where steam is not to be had. The result of the burning of this fuel in ordinary grates was shown to be very satisfactory, a good bright fire being maintained without trouble and with but very little ash. The machine is being introduced by the Universal Patent Fuel Machine Company, of 32, Fenchurch-street, London.—*London Times.*

CARTHAGENA BARK.

BY DAVID HOOPER.

[We give this paper as being much fuller than the one on page 300.—Ed. T. A.]

The following two papers were read and discussed together at the Twenty-fifth Annual Meeting of the British Pharmaceutical Conference on Wednesday, Sept. 5, 1888:—

Some of the cinchona barks are known by the names of the localities in which they are collected, others are named from the ports whence they are distributed, and perhaps none of these barks has been less noticed than that bearing the name of Cartagena in the United States of Colombia. As the botanical source of this bark will very probably be cleared up at an early date, it would be interesting in the meantime to link together historical facts on the subject, and to give the results of the experiments connected with the introduction of the Carthagena bark trees into the Nilgiri Cinchona Plantations of the Madras Presidency.

José Celestino Mutis, at the request of the Spanish Viceroy, was the first botanist sent out to explore the bark region of New Granada,* and discovered the first cinchona tree at Tena, in the year 1772. A few years later Ruiz and Pavon were sent round to Peru to investigate the bark regions of that country, and a hot discussion sprang up between the botanists as to the respective merits of the species they had discovered in the two countries. It would indeed seem that Mutis was not acquainted with the more valuable species of cinchona, as the large quantities of bark that were subsequently exported from Carthagena and Santa Martha were found to be so worthless that the barks of New Granada were brought into disrepute.

The distinguished traveller, Alexander von Humbolt, with Aimé Boupland, visited the ports of the Caribbean sea in 1801, and expresses an interest in the bark trade of South America. He says: "The proximity of the port of Carthagena would render the neglected cultivation of cinchona an object of great importance to European trade. The real febrifuge cinchona with the haray corella is nowhere else found so near the coast, if we except the Sierra Nevada of Santa Marta." Whatever might have been the value of the barks exported at this time, the trade was considerably brisk; it is shown in the Report of the Administrator that between 1802 and 1805 the shipment of New Granada bark from Carthagena was 3,240,000 lb., and the first arrivals in Spain sold at 5 to 6 dollars a pound.

Dr. Karsten, a German botanist, arrived in South America in 1844, and during a long residence examined the cinchona trees of New Granada, and determined the origin of several barks exported from the northern towns. He found *Cinchona lanceifolia* of Mutis to be a very valuable plant, and to furnish barks of very different appearance. This species, he says, affords principally two kinds of barks, the valuable variety called soft Colombian, or Calisaya, of Santa Fé, and the less valuable variety, called Carthagena, or Cogueta bark, or Carthagena cognate of the French. Other investigators refer the latter bark to the species named by Mutis, *C. rosulata*, a tree largely distributed in South America, and considered to be very poor in alkaloids. The same variety from *C. lanceifolia* was exported very largely between 1849 and 1855, but after that time the supply began to fail. About the year 1872 Colombian barks were again in the market, and 12 cwt. was shipped to Europe from Carthagena and neighbouring ports, but the bark trade at this time ceased to be characterized by one or two special kinds, as the Pitayo bark had been recently explored by travellers, and quantities of bark from this district formed the bulk of the exports. Within the last decade Remijns have been discovered

* In 1810, after the war with Spain, Colombia was proclaimed a republic. In 1831 the Confederation resolved itself into three independent states, New Granada, Venezuela, and Ecuador. In 1851 the former was reconstituted Colombia, with Bogota as chief town.

in the forests of Colombia, and cuprea barks have taken the lead in the commerce of that country; in 1881, for instance, out of 87,000 serons exported, 60,000 serons were cuprea bark.

The United States of Colombia at the present time probably yield the greater portion of the South American cinchona bark of commerce. The cuprea bark comes from low elevations at Antioquia in the north-west, from the basin of the lower Magdalena in the north, from Bucaramanga and Llanos on the eastern slopes of the eastern Cordillera, and from near the several affluents of the Orinoco and Amazon. The mountainous territory in the south-west affords the Pitayo bark and the Calisaya of Santa Fé, and includes the habitat of the Carthagena bark trees. In nearly every part of the country, from 9000 feet on the three branches of the Colombian trifurcation of the Andes, down to river basins a little above sea-level, are numerous rubiceous trees more or less valuable as quinine producers. The bark from this country is not all exported from Carthagena, but this port still holds an important position in the trade. In the consul's report on the trade of Carthagena for the year 1837, 135,000 pounds of cinchona bark were passed out, together with some drugs of less importance, as balsam, ippecacuanha, and sar-aparilla.

Mr. Robert Cross was employed in 1877-1878 to collect plants of the Calisaya Santa Fé on the eastern Andes and of the Carthagena bark on the Central Cordillera. This intrepid traveller and accomplished gardener made a successful journey through Cali and Popayan, over the western and central Cordilleras, and returned with cuttings and seeds of the plants for which he went in search. He defined the Carthagena bark region as situated on the eastern declivities of the central Cordillera on the border of the Magdalena Valley in the district of Paéz, a little below 3° north latitude. The tree grows at elevations of from 4000 to 8000 feet in forests with a heavy rainfall. It is rapid and robust in habit, and stands great variations in temperature. Five specimens of bark were collected from trees in the Cauca Valley, and one from Coralis Inza in the district of the Magdalena, and the latter was the only one that was found to contain quinine. The analyses of the six samples by Mr. J. E. Howard might here be conveniently reproduced.

	1	2	3	4	5	6
Quinine	·00	·00	—	·01	1·88	·00

No. 1. Paniquita variety, Popayan. 5000 feet, valley of the Cauca.

No. 2. Paniquita variety, Usenda. 8500 feet, district of the Cauca.

No. 3. Smooth leaved variety, Pueblo Nuevo, 5000 feet, district of Cauca. Mr. Howard remarks this is the *Quina Major* of Carthagena, and does not belong to the Cinchona, but to an allied family.

No. 4. Paniquita variety, Silvia. 7500 feet, district of the Cauca.

No. 5. Magdalena variety, Coralis Inza. 7000 feet, district of the Magdalena.

No. 6. Paniquita variety, 6000 feet, district of the Cauca.

The plants were taken to Kew, arriving there in March, 1878, and early cuttings were obtained from the root pieces of the plants; much difficulty was experienced in preserving the Magdalena plant, owing to the frost of the following winter and to the cockroaches feeding upon it. Next year the young plants were brought to India, and six Carthagens planted out on the Nilgiri, in October, 1880. The high elevation of Desudalia was avoided to insure free and more rapid growth, but two plants at Nilgiri were found to more gain strength, and even now three more are in fruit. Several specimens were sent to the plantations in June, 1881, and one of the five plants brought lately by Mr. Cross from the central cordillera

near Bogota (elevation 4000 to 6000 feet), are healthy and strong growing, and are being propagated. The prospects of establishing it on the Nilgiris is promising. It is supposed to be a strong growing and large tree, which its present appearance does not belie; its yield in quinine is much the same as that of succirubra, and it will probably succeed in the same localities as that species." Mr. Cross tells me that he believes the "China Cuprea" from Bogota is the same species. In 1884 they flowered and seeded, and in the same year 400 young plants were put out and grew rapidly.

One of the trees planted by Mr. Rowson in Ossington Estate, Naduvatom, was cut down and uprooted last year; it had been growing in a poor soil with a southern aspect, and was five and a half year old.

This year some bark was taken from an original tree six years old, on the Government Plantation, and examined with the other specimens, with the following results:

	Government Stem-bark	Ossington Stem-bark	Ossington Root-bark.
Quinine	—	—	1.10
Cinchonidine40	.22	.55
Quinidine	—	—	.36
Cinchonine	1.64	1.60	1.77
Amorphous alkaloid	1.51	1.33	.62
	3.55	3.15	4.40

The appearance of the bark was not very different to that of other species; the outer surface was marked by transverse rings at rather regular intervals and warty exuberances. The powder of the stem, and especially of the root-bark, was decidedly more yellow than other kinds of cinchona. Although this bark is known in some quarters as "hard Carthagenia," no particular hardness was noticed in the small sample from the locally cultivated trees; if the hardness depends upon the heaviness the name would not apply to this bark, as the specific gravity of some of the powder showed it to be like the cuprea, lighter than the red and crown barks. The analyses, however, are of the most importance, and these show the bark to have the same composition as those brought by Mr. Cross from Usenda and Sylvia in the district of the Cauca, and analysed by Mr. J. E. Howard in 1878.

It is very evident that this variety of Carthagenia bark, now being cultivated on the Nilgiris, is a very useless one commercially, and that the better kind, brought from the Magdalena valley, never reached India at all, or was one of the plants that was unsuited to the climate and died. Now we know of the little value of this species, its propagation will not be continued, a few trees only will be reserved for botanical identification and future chemical investigation. In the first analysis of the root bark the small quantity of alkaloid named quinine appeared to have some of the properties of homoquinine, an alkaloid found in cuprea bark, but further tests on a larger scale showed it to be chemically and physically identical with quinine. Cinchonidine was also readily detected in each sample, and as the absence of this alkaloid constitutes a perfectly distinct character of the Remijias, it is very clear that the barks above examined are from a separate species of cinchona from any of those hitherto introduced into India.

In concluding this paper I must acknowledge the use I have made of the works of Markham, Howard, Kaisten, Triana, Humbolt, Cross, Flückiger, Van Gorkom, the Reports of the Madras Government, and the statistical notices of the cinchona trade in the *Pharmaceutical Journal and Chemist and Druggist*.

THE HYBRIDISATION OF CINCHONAS.

BY DAVID HOOPER, F.C.S., F.I.C.,

Government Quinologist.

The hybridisation of plants belongs to the department of vegetable physiology, and when plants contain alkaloids and principles which admit of precise quantitative determination, the processes of Nature might well be studied from a chemical point of view. Cinchona hybrids have received a great deal of attention from a number of botanists, and without re-

producing the different conclusions arrived at, and only using botanical terms sufficient for explanation, I intend to treat the subject in the light of the chemical analysis of the barks.

There are two well-defined species of Cinchona on the plantations of the Madras Government, the one is *C. succirubra* (Pavon), yielding red bark, and the other *C. officinalis* (Hooker), yielding the crown bark of commerce. Between these two species, many hybrid barks are recognized, and have been cultivated and exported to a very large extent from this country, and the time has come when their nature should be thoroughly investigated. The facility with which these plants made their appearance on the estates seems to imply that forms of cinchona were produced that were more adapted to the climate and situation of their adopted country than the parent forms brought originally from South America. Those having a greater vigour of growth should be propagated, as the robust habit is usually indicative of a richer bark. Hybrids assume the quick growing character of the succirubra, yet they contain a greater proportion of quinine than that species. They do not as a rule contain the percentage of quinine usual to officinalis, but the large quantity of bark yielded by the tree, and the high total alkaloids, make them equal in value to the best crown barks.

It will first be necessary to discuss the alkaloidal composition of the two species between which hybridisation on the plantations has taken place, and for this purpose the analyses of natural stem bark will be quoted, excluding branch, root, and all barks submitted to artificial treatment. *Cinchona succirubra* has a peculiar centesimal arrangement of alkaloids in its bark varying between certain limits. In the following table it will be seen that in fifty selected barks the quinine ranges from 17 to 27 per cent., cinchonidine from 26 to 51 per cent., cinchonine from 17 to 47 per cent., and amorphous alkaloids from 4 to 23 per cent.; besides these the alkaloid quinidine occurs in traces in red barks, and occasionally reaches 0.5 per cent.

Average	41.2	40.9	0.5	9.7	7.7

The above analyses were made on the natural bark of individual trees from 7 to 16 years of age, and they are arranged according to their value in quinine, which occurs from 55.3 to 30.8 parts per 100. The figures for cinchonidine more or less increase with the decrease of quinine; these two alkaloids together form four-fifths of the whole. The quinidine as a rule is found in those barks in which the quinine predominates, and in that kind called pubescens. With regard to the less valuable alkaloids, it is very satisfactory to notice their deterioration in the hybrids compared with the species; the cinchonine is seen to be in the same small proportion peculiar to the crown bark, and the amorphous alkaloids, commercially regarded as worthless, are much lower than in the red bark.

The arrangement of the analyses according to the percentage of quinine shows how the hybrids take up an intermediate position between the succirubra and officialis. The highest amount of quinine in the succirubras is the lowest in the hybrids, and the highest in the hybrids merges into the lowest in the officialis. This illustrates the complete fusion that takes place in the alkaloids of the barks through the process of species-hybridization.

Several plots at Naduvatam are devoted to the cultivation of hybrids, and the plants, as might be expected, are of many varieties. About 70 per cent. are forms of hybrids previously noticed and the remaining 30 per cent. is a mixture of the two parent species and a few other new strains. A few analyses of barks from selected trees of five years of age will show the variety of forms raised from hybrid seed.

Character of trees.	Quinine	Cincho- nidine.	Quini- dine.	Cincho- nidine.	Amor- phous Alka- loids.	Total.
1 Hybrid	3.32	2.99	—	.41	.49	7.21
1a "	2.58	2.91	—	.33	.63	6.55
2 "	.87	.98	.13	2.96	.70	5.64
2a "	.90	2.75	—	1.05	.40	5.10
3 Officialis	2.85	1.11	.11	.46	.35	4.88
4 Succirubra	.85	1.24	.15	2.79	.57	5.60
5 Officialis	3.10	1.88	.09	1.17	.56	6.80
6 Succirubra	1.35	2.67	—	1.36	.96	6.34

No. 1. Height 9 feet. Girth 6 inches. Leaves broadly ovate, crumpled, glabrous, dark green, glossy above, strongly pubescent beneath, 6 x 4 inches, base rounded or slightly produced on the leaf-stalk.

No. 2. Height 10 feet. Girth 6½ inches. Leaves 8 x 4½ inches, ovate, flat, glabrous above and beneath, as also the young shoots, dark green, shining base rounded or slightly produced.

No. 3. Approaching the officialis type. Height 9 feet. Girth 8 inches. Leaves 5 x 3 inches, very broadly ovate, dark green, shining above, glabrous on both surfaces, base rounded, scorbiolæ on upper surface prominent.

No. 4. Approaching the succirubra type. Height 8 feet. Girth 7 inches. Leaves broadly ovate, shining above, slightly puberulous beneath, dark green, crumpled, produced at the base.

No. 5. Approaching the officialis type. Height 9 feet. Girth 5½ inches. Leaves 4 x 1½ inches, lanceolate, narrow, perfectly glabrous, dark green glossy, folded inwards upon the upper surface, leaf-stalk reddish.

No. 6. Approaching the succirubra type. Height 10 feet. Girth 8 inches. Leaves and young shoots pubescent. Leaves 10 x 8 inches, light green, variable in size, crumpled, base scarcely produced.

The two barks marked "1" and "1a" are in appearance like the pubescent hybrid, and their analysis confirms to some extent the resemblance in that they contain a large proportion of quinine and cinchonidine in their alkaloids. Nos. 2 and 2a have the habit of the magnifolia hybrid, but the presence of quinidine and the large amount of cinchonidine and cinchonine respectively, indicate new features in the alkaloidal composition that might be referred to new forms produced by hybridisation. Nos. 3 and 5 are the broad-leaved and narrow-leaved officialis, and are very characteristic in their analyses. Although the latter is the richer of the two, it is superseded in quinine and totals by the first pubescent hybrid. Nos. 4 and 6 are the dark and light-green-leaved varieties of succirubra. The analysis of the former corresponds throughout with the glabrous hybrid No. 2, while the analysis of the latter reveals a composition almost identical with the true type of the Nilgiri succirubra. In the plot where these barks were collected it was noticed that the trees of the parent forms flowered and seeded sooner than the hybrids, but on the other hand the hybrids were more vigorous in their appearance and had more foliage than the species; this perhaps, is in confirmation of a botanical law that in hybrids the growth is strong but the sexual functions are weak.

Before concluding the subject some analyses might be quoted of hybrids grown in the Bengal Government Cinchona Plantations at Mongpoo, near Darjeeling, at 3500 feet elevation. The results are very interesting in showing the difference between hybrids from foreign localities grown in the same situation. The three kinds were from trees raised from seed from Jamaica, the Nilgiris and Mongpoo, and each sample was taken in strips from about forty trees of varying types. Mr. J. A. Gammie, in sending the samples, says, "Here at Mongpoo our own type of hybrid yields quite double the bark that the Nigiri type does, whilst it in its turn yields double as much as the Jamaica sort. Perhaps on the Nilgiris our type would be the poorest of the three. The Nilgiri and Jamaica plants approach much nearer than ours to the officialis, a species that is a failure with us."

	Jamaica.	Nilgiris.	Mongpoo.
Quinine	2.22	2.47	2.02
Cinchonidine	1.93	1.98	2.50
Quinidine	—	—	.17
Cinchonine	.75	.58	.66
Amorphous alkaloids	.64	.59	.31
	5.54	5.62	5.66

In this case it would be misleading to place much importance upon the analysis of the bark alone, as the samples are pretty equal in value, considering their content of alkaloids; but, taking into account the fact that the Mongpoo hybrid yields so much more bark than the others, it would, of course, be more remunerative to cultivate this variety in the Himalayan plantations.

In a future report to the Conference I hope to be able to give the results of a large number of analyses of the Ledger hybrid, a cross between two species of cinchona, the *C. Ledgeriana* and *C. succirubra*.

The PRESIDENT, in proposing a vote of thanks to Mr. Hooper, said the Conference might be congratulated on being the medium of the publication of two such valuable papers.

Mr. GROVES asked whether the result of the hybridization would not be affected by the selection of the parents,—whether the male parent should be of one kind or another. The paper did not state anything on that point, but he should imagine, though he knew nothing about hybridisation, that it would affect the result very materially.

Dr. PAUL said it was somewhat difficult to offer any remarks on a paper which went into such a mass of detail; but incidentally he should like to point out that the mode in which these figures had been placed before the meeting illustrated in a striking manner the disastrous consequences of the enterprise which had been pushed forward with so much unusual zeal by the Government in India. The introduction of cinchona cultivation in India seemed to have been marked by mishaps. The selection of succirubra plants under the influence of the red bark craze, which prevailed some years ago, had been perhaps the most pernicious step which had been taken. The bark of the trees of that type cultivated in India had certainly shown an improvement on the red bark brought from South America, but it was characterized by the presence of such a large proportion of the more worthless alkaloids that practically red bark was at present almost worthless as a source of quinine. The cultivation of other kinds of bark, crown especially, had resulted in a very much more favourable production of alkaloids, not only in regard to the total quantity, but in their relation to each other. The reputation of the officialis barks, which used to be known as Loxa bark, was almost gone as an alkaloid-yielding bark; but when that tree was grown in India it produced bark yielding two, three, four, and sometimes as much as seven or eight per cent. of sulphate of quinine. However, official prejudice was in favour of the red bark, which had been largely cultivated, and wherever that was the case it had not only produced bark comparatively valueless in itself, but it had spread a degrading influence to all the neighbouring plantations, and so the hybrid referred to in the paper had been brought into existence. He could not regard the figures given as having any value beyond showing the unfortunate result which had almost brought about the ruin of the succirubra planter, the quinine manufacturer, the bark merchant, and everybody connected with the industry. Cinchonidine and cinchonine were exceeding the table in much greater quantity than was wanted, and at the same time the quantity of red bark grown had increased to such a point that it had become literally so much a drug in the market that no use could be found for it. Moreover, the comparison between the barks as shown by the table was not accurate. The crown bark as described there was what would be called by everybody acquainted with bark a very mean specimen. The proportion of alkaloids yielded by crown bark of any value was from 3 to 5 per cent. of sulphate of quinine, with something less than 1 per cent. of cinchonidine, but in the author's table there was a statement that crown bark of average composition gave half as much cinchonidine as quinine, which was altogether wrong. Passing on to the red bark the conditions were reversed, and in favour of that craze about 1870 or so to which he had already referred. The well known proportions in red bark were 1½ per cent. quinine with 1, 4, and 5 per cent. of cinchonidine. The result of a cross of hybrid bark a ruin was what he should call a pity. He would say, for one of a table of analyses of the Ledger hybrid, which you give in your paper, that the figures are not, but such figures represented nothing which really existed in nature, and were of no kind of value. The introduction of Carthagena bark was another illustration of the misguided way

in which the cultivation of cinchona had been carried out. There was no reason why Carthagena bark should be cultivated to any extent in India as an article of produce. So long as it existed in South America, and a good price could be got for it, it was very well to import it and work it, but to propagate its existence was not at all desirable. The kinds of bark fit for cultivation and encouragement were the crown bark and the calisaya, but above all things the crown as being rich in its yield, comparatively more hardy than any other, less liable to decay, and in every respect the best kind of bark to use. The feeling in favour of succirubra had extended even to the Pharmacopœia, with the result that every bark preparation that appeared there was in fact an officially adulterated article. Those preparations were made, not with such a drug as was formerly ordered, crown bark or calisaya, but with the most inferior bark that could be selected, which contained for every unit of quinine, the only really valuable constituent, 2, 3, or 4 per cent. of the comparatively valueless ones.

Mr. HOPEKIN said he was glad to be able to corroborate in great measure what Dr. Paul had said. The way in which the centesimal analyses were presented was most fallacious, because for these percentages to be of any good whatever it could be necessary to assume that the percentage of the total alkaloids of the bark was the same in the various species; but everybody who knew anything about the total percentages of alkaloids in these barks must know that the percentages were not by any means equal, but that in some barks they were very much higher than in others. With regard to the crown bark analyses the figures did not represent a typical *officinalis*. If you took the analyses and examined the proportion that the quinine and cinchonidine held to one another, you could only come to the conclusion that the bark was a hybrid and not the *C. officinalis* which the Indian Government had in their own plantations. In the Nilgiri hills they had a plantation of the *Officinalis*, var. *Uritusinga*, cultivated from some plants his uncle, the late Mr. J. E. Howard, gave them some years ago, and large quantities of the bark had been sent to this market, but the analyses shown by no means represented that bark. Mr. Hooper had started with bark which was by analysis most certainly hybrid. Then he took the mean of that analysis and that of a succirubra—which he had really no right to do because the total percentages varied so immensely—and proceeded to build up a theoretical hybrid upon it. What the Indian Government ought to do was to take a hint from the Java Government. They had a kind of "*Calisaya-succirubra*" hybrid which Mr. Hooper alluded to in his paper, and some of the private growers in Java had had this bark on the market for some years. On testing, it gave 7 to 8 per cent. of pretty nearly pure sulphate of quinine. This bark, when examined carefully, presented the peculiar characteristics and marking both of the calisaya bark and of the succirubra. Mr. Hooper carefully left out any reference to what might be called the celebrated Indian hybrid, the "*robusta*" bark which was produced by Col. Beddome when he was director of the woods and forests. It did not appear from the figures shown what the percentage of alkaloids was, and therefore he could make no comparison between these government hybrids and those which were on the market. The robusta bark in the Madras forests contained 4 to 4½ per cent. of sulphate of quinine, and sometimes one came across a hybrid from Ceylon, which was a calisaya hybrid, either with the *officinalis* or the succirubra, which came up to 6 or 8 per cent. Those were the hybrids the Indian Government ought to go in for.

Dr. THURSH, in reply to Dr. Paul said Mr. Hooper gave in the paper in detail the analysis of the barks, and also the mixture and formula, and in two cases calculated out tables of means. He (Dr. Thursh) had simply calculated out the other two so that they might be compared, although the tables might be of no value in themselves, if they contained the tables in which the details were given, it would be found there was a considerable fund of information to be obtained.

Dr. PAUL said he had no desire to throw any discredit on the labour Dr. Thresh had so kindly given to make the paper understood; he merely referred to the illustration which the tables afforded of the fallacies and mistakes of the Indian cinchona cultivation.

Mr. HODGKIN, in reply to Mr. Groves's question, said, to begin with, the bulk of the plants would take the form of whichever parent was the stronger plant, and not of the other one, so that in some parcels containing hybrids from the same plants originally, from calisaya and succirubra, it might be found, if the calisaya had been the stronger plant to begin with, that the resulting bark would test better than if the succirubra had been stronger.—*Pharmaceutical Journal*.

COFFEE AND TEA IN THE UNITED STATES: SIMULTANEOUS DECREASE IN THE CONSUMPTION OF

COFFEE AND INCREASE IN TEA.

The imports of coffee into the United States for the year ending June 30, as reported by the Government were 92,463,396 pounds less than during the preceding year, comparing with previous years as follows:

Year.	Imports Pounds.	Exports Pounds.	Consumption Pounds.
1888 ...	433,645,774	15,083,019	418,562,755
1887 ...	526,109,170	25,289,583	500,819,587
1886 ...	564,707,533	27,495,752	537,211,781
1885 ...	572,599,552	33,335,196	529,264,356
1884 ...	534,785,543	26,152,679	508,632,863

Average yearly. 526,369,514 25,471,246 500,898,268

In glancing over the above table the first question it prompts is, Why has the consumption decreased every year since 1885, until during the year just closed it fell 82,335,513 pounds below the average yearly consumption for five years past, and this in face of an increasing population and general prosperity?

High prices, as the result of short crops, and speculation are the two chief factors in bringing about the remarkable change noted.

The following table shows the cost per pound of imports, based upon value as declared at custom houses, and the per capita consumption, based on Prof. Elliott's table of population:

Year:	Cost per pound.	Per capita Consumption pounds.
1883 ...	16	6.81
1887 ...	10.7	8.36
1886 ...	7.6	9.20
1885 ...	8.2	9.45
1884 ...	9.3	9.16

Within two years coffee advanced 113 per cent., a rise which placed a premium upon the use of substitutes and caused many consumers to abandon the berry for tea.

The consumption of the latter has increased 23,883,554 pounds, or 39.7 per cent. within five years, as the following statement of imports and consumption shows:

Year.	Imports.	Exports.	Retained for consumption.
1888 ...	84,627,857	682,350	83,945,498
1887 ...	89,831,221	2,350,035	87,481,183
1886 ...	81,898,522	3,015,697	78,882,825
1885 ...	72,104,956	5,730,591	66,374,365
1884 ...	67,665,910	7,603,966	60,061,944

The above table shows an average yearly consumption during the past five years of 75,349,164 pounds; that for the year ending June 30, 1888, being 8,596,334 pounds above the average yearly consumption, against a decrease of 82,335,513 pounds in the consumption of coffee below the annual average of the same period.

The cost of tea has decreased and the consumption increased, the cost per pound as declared at the custom house, and per capita consumption comparing with that of coffee as follows:

Year.	Tea		Coffee	
	Average cost per pound. Cents.	Per capita c'n's m't'n Lbs.	Average cost per pound. Cents.	Per capita c'n's m't'n Lbs.
1888 ...	15.7	1.36	16	6.81
1887 ...	18.7	1.46	10.7	8.36
1886 ...	19.6	1.33	7.5	9.20
1885 ...	19.5	1.22	8.2	9.45
1884 ...	20.2	1.18	9.3	9.16

It is claimed that one pound of tea is equivalent to four pounds of coffee, as to quantity of infusion. In a country as large as the United States there are many whose purses would force them to abandon coffee at high price and substitute tea. One pound of tea costing at retail fifty cents would last a family of five as long as four pounds of coffee costing from \$1 @ 1.20. Necessity knows no law, and therefore the unskilled laborer and the needy farmer have been forced to buy tea instead of coffee. This is not true everywhere, but in enough territory to make the changes noted. That probably accounts for the great disparity recorded in the per capita consumption of tea and coffee in the United Kingdom as compared with this country, and which is here shown:

Year.	United Kingdom		United States	
	Unit'd Coffee. Pr cap. Lbs.	K'gd'm Tea. Pr cap. Lbs.	United Coffee. Pr cap. Lbs.	States Tea. Pr cap. Lbs.
1887 ...	0.80	4.89	8.36	1.46
1886 ...	0.88	4.83	9.20	1.33
1885 ...	0.91	4.93	9.45	1.22
1884 ...	0.91	4.82	9.16	1.18
1883 ...	0.90	4.74	8.9	1.23

The demand for chicory has rapidly increased during the period marking the rise in coffee as shown by the following statement of the quantities and values of chicory root, burned or prepared, ground or unground, imported into the United States during the years ending June 30, 1884 to 1888:

Year ending June 30:	Pounds.
1884 ...	1,730,298
1885 ...	4,239,370
1886 ...	3,415,655
1887 ...	5,227,995
1888 ...	6,762,473

Fifty years ago a supply of 150,000 tons of coffee was needed to meet the consumptive requirements of Europe and the United States. In 1848 the two countries absorbed 250,000 tons, in 1867, or just twenty years ago, 375,000 tons, or little less than one-half of the present consumption, which in 1887, reached 703,714 tons.

To meet the home demand, we import 75 per cent. of the supply from Brazil; about 11 per cent. from Venezuela; 6 per cent. from the West Indies; 5 per cent. from the East Indies; 3 per cent. from Central America and sundry points.

The exports of coffee from Brazil for the past five years, ending June 30, were as follows:

Year	Rio.	Santos.	Total.
1888 ...	1,879,174	1,310,209	3,189,383
1887 ...	3,453,353	2,493,228	5,946,581
1886 ...	3,642,202	1,660,169	5,302,371
1885 ...	4,093,889	2,175,627	6,269,516
1884 ...	3,086,446	1,919,793	5,006,239
Total ...	16,155,064	9,559,026	25,714,090
Average ...	3,231,013	1,911,805	5,142,818

The above table reveals the cause of the rise in the cost of the bean, the deficiency in the Brazil crop falling 2,570,619 bags below the average annual supply for the five years, 1833-37. This was a decrease of 151,212 tons, or nearly one-fourth of the world's annual requirements. This year there is promise of a supply equal to the world's requirements. Speculators, in forcing up the price of coffee until it reached 22½ cents for Fair Rio in June, 1887, failed to estimate correctly the power of high prices and the

substitution of tea, and adulterants of coffee, to force a reduction in consumption as an off set to short crops. The outlook is once more in favor of cheap coffee as the profitable character of the industry since 1885 has stimulated the setting out of new plantations, the effect of which will be left in 1890.—*American Grocer.*

THE USE OF DIVI-DIVI IN TANNING LEATHER.

In tanning with divi-divi, carefully selected pods deprived of their seeds should be used. They may be reduced to powder, or roughly broken, and infused in either cold or warm water. Divi-divi may be used either as a pure or mixed tannage, i. e., skins soaking in divi infusions may be stratified with layers of the material itself, or with layers of other tanning material, or, *vice versa*; infusions of other material may have layers of divi-divi for stratifying skins and hides soaking in them. This plant possesses certain advantageous qualities that ought to find favor with tanners, were it not that they are more than counter-balanced by its bad qualities. It is rich in tannic acid, containing from 30 to 40 per cent., and if tannic acid alone were taken as a standard in estimating the value of tanning materials, divi-divi would take the palm of most others. But tannic acid, though the chief, is not the only factor in the formation of leather; it simply forms *tanno gelatine*, and it requires something more than mere tannic acid to form real leather. Experience also teaches that in course of manufacture skins and hides, while soaking in infusions of bark, etc., stratified with layers of the material used in order to facilitate absorption, absorb other matter held in solution besides tannic acid. This soluble matter contains coloring matter, and characterises the leather when tanned, giving it color and other qualities desirable or otherwise; it is known in the trade as "extractive matter." Leather, like all other commodities, in order to be marketable, is judged by a certain standard such as color—from a light brown to cream. It must be mellow, close in texture, silky to the feel in case of skins, and firm though pliant in the case of hides. In fact, it must take the eye. Such being the case, it is quite natural that a tanner will look about him for some material yielding an extractive matter producing these results, and such a material we have in the bark used in the Madras Presidency.

Divi-divi possesses the excellent and much desired property of giving weight to leather, but yields an extractive matter producing most disagreeable results; it imparts a reddish brown color to the material, which is very often horribly streaked. It also possesses that worst of all properties, gallic fermentation, which may be reckoned among the worst of the tanner's enemies, as it is a great source of loss and annoyance to him, though, in its way, gallic acid is very useful to him. All materials containing tannic acid are subject more or less to gallic fermentation, but divi-divi possesses this property in an extraordinary degree, fermenting rapidly under an increase of temperature even in the presence of antiseptics, so that it is not suited to India, where more favorable tanning materials abound, and where, in the absence of scientific skill in the trade, these difficulties cannot be contended against. From a few specimens of divi-tanned leather that I have by me I find that it is influenced by the weather, having the peculiarity of being firm in the dry, and soft and flabby in the wet weather. In some of my experiments with divi-divi, when the temperature of the atmosphere had risen, I found that gallic fermentation set in within a few hours, so much so that I suspected the presence of ferrous matter, and had to use vessels scrupulously clean, and into these I introduced fresh infusions together with a small quantity of an antiseptic, and found that gallic fermentation is lost in, then a not in so marked a degree as when not antiseptic; it was only by means of an antiseptic that I succeeded at all in tanning with divi-divi. From the incident, on appearance of the surface of the finished I saw that the rapidity with which described fermentations set

to the presence of a soluble oil, or fatty matter; but with the limited quantity at my disposal I was unable to make further experiments to bear out this inference which, after all, may be a mistaken one. Divi-divi should find favor in Europe, where tanning materials are scarce, as it has certain advantages over other imported materials, such as its comparative cheapness, richness in tannic acid and its excellent weight-giving property. Moreover, its disadvantages can be better contended against where the climate is more favorable, and where science and modern appliances are brought to bear on them with very favorable results. Science in all its branches is making giant strides in this wonderfully progressive century of ours, and the tanning community, hitherto a few centuries behind time, contented to walk on the same lines chalked out by their forefathers, are awaking to the fact that science must go hand in hand with their trade as it does with most others, with the result that ere long obstacles supposed to be insurmountable will yield to its influence. Probably in the near future divi-divi will, in the estimation of tanners in Europe, rank among their chief imports. In conclusion, I would suggest to those who have both the means and leisure, and are interested in seeing this article a commercial success, to make an extract of it, as tanners in Europe affect extracts preferably to the materials themselves. An extract would be more advantageous to the exporter as it would find more ready sale than the material itself, provided it is free from foreign matter; moreover, the cost of freight is comparatively far cheaper. In making the extract good colored and well-matured pods should be selected, and all discolored and decayed ones rejected. The pods may be roughly broken, or reduced to powder and digested in hot or cold water, the latter where a good colored extract is required, and the former where tannic acid is the chief object. Another suggestion I would make is to mill the pods prior to making an extract, in order to see if oil in any appreciable quantity can be obtained. A quantity of carefully prepared extract, sufficient at least for a fair, if not exhaustive, trial should be sent either to Europe, or to some local tanner willing to make experiments with it himself, without entrusting it entirely to the hands of his servants.—E. G. THORPE.—*Madras Mail.*

TEA-LEAF PLUCKING AND CARRYING IN UVA.

A Badulla planter lately told me that his pluckers a day or two previously had plucked from 5 to 13 lb. per cooly by 11 a.m. from a rather straggling and irregular field, and the kangani tasked the coolies to bring in 20 lb. each, from 11 to 4 p.m., as they had more regular tea and a better flush. He thought the task too much, but to see if it were possible he promised 3d each to every cooly who brought in the 20 lb. at 4 p.m. and to his surprise 39 pluckers out of the gang brought over 20 lb. each and got their 3d each, while all the rest had also done well. He also told me that he finds he can transport leaf on coolies' heads a distance of about four miles in ordinary *ponny bags* without the leaf being the slightest bit injured, and that it is really a waste of labour and money to make coolies carry loads of leaf in these large baskets, and that he shall do so no longer.—*Con.*

USEFUL HINTS TO TEA PLANTERS: HAWES & Co's FORNIGHTLY CRYSTALS TEA REPORT.

London, 14, MARK LANE, 26th October, 1888. The following quantities have been offered at Auction since our last issue, dated 12th October:—

Oct. 15th	2,801	pkgs.	which sold at an average price of	1 1/4	per lb.
" 18th	169	"	"	1 1/4	"
" 23rd	3,812	"	"	1 0/11	"
" 25th	1,229	"	"	1 0/11	"

The average price realized for the past, compares favourably with that of the previous fortnight, being 1s 1-16d per lb., against 1 1/4d per lb. The teas offered have, shown generally improved quality and received keen competition from the trade, and late full and profitable prices have been easily obtained; this is owing to the moderate quantity offering, and to the trade recognising the fact, that the exports will be less than estimated, namely, 23,000,000 lb. Judging from latest advices from Colombo, we anticipate the season's crop will be about 2,000,000 lb. short. The greatest demand has been chiefly for fine and choice Broken Pekoes, Pekoes, and good liquoring Pekoe Souchongs, which we quote fully 1/2d to 1 1/2d per lb. dearer. Medium and common Pekoes show the least improvement, while the lower grades of Pekoe Souchongs, Souchongs, and Broken Teas are about 1/2d per lb. dearer. In our opinion the following gardens have represented the best and most useful teas for this market:—"Chapelton," "Dickoya," "Hope," "Elbedde," "Glen Alpin," and "Goatfell."

PERCENTAGE OF GRADES SOLD IN PUBLIC AUCTION.

Oct.	Broken Pekoe, per cent.	Pekoe, per cent.	Pekoe Souchong, per cent.	Unassorted and Souchong, per cent.	Souchong and Congou, per cent.	Broken Tea, per cent.	Dust, per cent.
16th	26	30	19	5	12	7	8
18th	21	42	21	—	5	1-7th	7 3-7th
23rd	26	33	23	—	5	1-7th	8
25th	29	26	22	—	5	1-7th	8

RANGE OF PRICES REALISED DURING THE FORTNIGHT.

Broken Orange Pekoe and Orange Pekoe	Broken Pekoe	from	to
Broken Orange Pekoe and Orange Pekoe	Broken Pekoe	10 3/4d	1s 11d.
Pekoe Souchong	..	9 1/4d	1s 8 1/2d.
Souchong and Congou	..	8d	1s 1 1/2d.
Broken Tea and Broken Pekoe	..	7d	11 1/2d.
Dust	..	5d	10 1/2d.
Unassorted	..	3 1/4d	1s 3 1/4d.

We would draw Planters' attention to the following tables, and our explanatory remarks with reference to "Weighing Teas," which if strictly adhered to will save loss in weight between Colombo and London. Planters must also keep in mind that all teas must be packed in well-seasoned wood, if not, it will dry on the way home, causing the weight to be different, and probably damage the flavour and condition of the tea.

HOW TEAS OUGHT NOT TO BE PACKED.

Actual Gross Weight of each Package in Ceylon, including all iron hooping, nails, &c. 139 lb. 15 oz.
 Customs Gross Weight in London 139 lb.
 Actual Tare or Weight of each Empty Package in Ceylon 40 lb. 1 oz.
 Customs Tare in London 41 lb.
 Actual Nett Weight in Ceylon 99 lb. 14 oz.
 Customs Nett Weight in London 98 lb.

In the above example it will be seen that the importer loses 15 oz. on both the gross and tare, say

1 lb. 14 oz. per package, and, though this may be termed an extreme case, yet it frequently occurs.

HOW TEAS OUGHT TO BE PACKED.

Actual Gross Weight of each Package in Ceylon, including all iron hooping, nails, &c. 140 lb. 2 oz.

Customs Gross Weight in London 140 lb.

Actual Tare or Weight of each Empty Package in Ceylon 39 lb. 14 oz.

Customs Tare in London 40 lb.

Actual Nett Weight in Ceylon 100 lb. 4 oz.

Customs Nett Weight in London 100 lb.

The loss, it will be observed, is only 1/4 lb. per package. Should, for example, a package be found to tare (which tare must be ascertained before filling in every case) 39 lb. 13 oz., then 100 lb. 2 oz. must be packed in order still to make the gross 104 lb. 2 oz., tare 40 lb.= 100 lb. nett; but in the event of packages taring, say, 39 lb. 12 oz., 11 oz., or 10 oz., these packages must be increased in weight by adding wood to the interior, so as to bring them up to the requisite standard, viz., 39 lb. 13 oz. or 14 oz. Although 39 lb. 13 oz. or 14 oz. is given as an example, it is immaterial that all the packages should run the same; the great principle is that the tare of all should be 2 oz. or 3 oz. under a pound.

Teas, if properly bulked, are always weighed nett; that is, the contents of 10 per cent. of each break is weighed in bags, and the average nett weight represents the parcel.

Care should be taken by packers in Ceylon that the nett weights run as evenly as possible; 2 oz. or 3 oz. should be allowed as overweight in each package.

We think that if more Ceylon Teas were packed in Chests it would be advisable.

We venture to give our criticisms on most of the complete invoices of Estate Teas, sold during the past fortnight, which we hope may be of interest to those concerned, and may shew estate owners the condition in which their teas are received here:—

Estates—Teas—Descriptions.

Hope.—Broken pekoe, pekoe and souchong:—Rather well-made leaves, malty, good Ceylon-flavoured liquors.

Adam's Peak.—Broken pekoe, pekoe, pekoe souchong Well-made leaves, thick, malty, Ceylon-flavoured liquors.

Uva.—Orange pekoe:—As orange pekoe too bold, being more like an Indian pekoe. Pekoe:—Too bold, pekoe souchong leaf, and wanting tip. Good pekoe-flavoured teas.

Laxapana.—Broken pekoe:—Black and tippy leaf. Pekoe and pekoe souchong:—Good style. Flavoury, but too thin.

Dickoya.—Broken pekoe, pekoe, pekoe souchong. Well-made leaves, fair strength, good pekoe-flavoured tea; desirable trade teas.

Glencairn.—Broken pekoe:—Too small. Pekoe and pekoe souchong:—Too brown and mixed. Fair strength, rather soft flavour.

Goorookelle.—Broken pekoe:—Too dusty. Pekoe:—Unevenly rolled and too dusty. Pekoe souchong:—Badly rolled, open and choppy leaf. Thick, rather coarse liquors.

Rangbodde.—Broken pekoe:—Fairly well made leaf, too dusty. Pekoe:—Evenly twisted leaf. Pekoe souchong:—Fairly rolled, wanting tip. Thick, rather soft, flavoury teas.

Nanoo-oya.—Broken pekoe:—Too small and too dusty. Pekoe:—Fairly-made leaf. Pekoe souchong:—Too dusty and choppy. Dull, strong, rather coarse liquors.

Gorthie.—Broken pekoe:—Good style, but too dusty. Pekoe:—Rather well twisted, tippy leaf. Fair strength and flavour.

Dalleagles.—Fair strength, rather malty.

Atherfield.—Broken pekoe:—Uneven and too dusty. Pekoe:—Good style, rather choppy, wanting tip. Pekoe souchong:—Rather open leaf. Plain liquor, wanting strength and flavour.

Deanstone.—Broken pekoe:—Rather small flaky leaf. Pekoe:—Fair pekoe leaf. Pekoe souchong:—Brownish, unevenly made leaf, rather dusty. Rather thin, little burnt flavour.

Queensbury.—Good style of leaves all round:—Thick, rather soft, flavory teas.

Malahiti.—Fairly made evenly rolled teas:—Strong, brisk, flavory liquors.

Glen Alpin.—Broken pekoe:—Uneven, mixed, rather flaky leaf, few tips. Pekoe No. 1:—Rather well made leaf, little tippy. Pekoe No. 2 and pekoe souchong:—Too choppy and dusty. Desirable trade teas, fair strength and quality, good flavour.

Hindagalla.—Broken pekoe:—Fair broken pekoe leaf, wanting tip. Pekoe:—Fairly twisted, rather uneven leaf, wanting tip. Pekoe souchong:—Fairly made, rather choppy. Fair strength, flavory, but too soft.

Dedugalla.—Fairly made leaves, rather too choppy:—Fair strength, thick soft flavour.

Gallebodde.—Rather well made, evenly rolled teas. Broken orange pekoe:—Too small and flaky. Fair strength, plain, soft, flavory liquors.

Mariawatte.—Too choppy:—Thin, and wanting flavour.

Hillside.—Loosely twisted leaves, wanting tip:—Thick soft flavour.

Summerville.—Fairly made leaves:—Fair flavour, and quality rather thin. Imboolpittia.—Loosely twisted bold leaf:—Plain soft, flavory teas.

Katooloya.—Unevenly rolled, little dusty:—Rather thick, wanting quality.

Elbedde.—Well made desirable teas:—Thick, good quality, desirable trade teas.

Anfield.—Broken pekoe, pekoe, fairly made. Pekoe souchong:—Rather too bold and open. Pure, good flavour, rather thin.

Chapelton.—Broken pekoe:—Fair broken pekoe leaf, few tips. Pekoe:—Small wavy leaf, wanting tip. Pekoe souchong:—Fairly twisted leaf, rather choppy. Very flavory, but rather too thin.

Kintyre.—Broken pekoe:—Too small and flaky. Pekoe:—Irregular leaf, few tips. Broken pekoe souchong:—Open, choppy leaf, dusty. Little flavory, thin and poor quality.

Moray.—Broken pekoe and pekoe:—Fairly made leaves. Pekoe souchong. Rather irregular and choppy. Fine, pungent, flavory teas.

Humesgeriya.—Well made leaves all round:—Thick, plain, useful teas.

Goddes.—Rather well twisted leaves:—Fair quality and flavour, but wanting strength.

Youldell.—Blackish, fairly made leaf:—Brisk, flavory, rather coarse.

Andromedha.—Broken pekoe:—Fairly made, leafy broken pekoe, few tips. Pekoe:—Fairly twisted leaf, wanting tip. Pekoe souchong:—Unevenly rolled choppy leaf. Soft on sour flavour, rather thick.

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LIMITED.

Report by the Directors of the Scottish Trust and Loan Company of Ceylon, Limited, to the twenty ordinary general meeting of shareholders, to be held within the Company's Registered Office, No. 123 George Street, Edinburgh, on Friday, the 26th day of October 1888, at three o'clock p.m. The Directors beg to present their twentieth report to the shareholders, being for year to 31st August 1888.

ESTATES IN COMPANY'S POSSESSION.—There have been carefully farmed. The cultivation of coffee and cinchona is continued whenever it is thought advisable, while tea planting is steadily proceeded with. A tea factory has been erected at Anfield, and preparations have been commenced for building a permanent one at Alwicket. The return for the year was 56,019 lb., as against an estimate of 41,000 lb. The estimate for the current year is 128,000 lb. The decrease on the net return upon the estates, as compared with last year, arises largely from the loss of orange pekoe and coffee.

PROFIT AND LOSS ACCOUNT.—This has been carefully estimated. As in former years the actual receipts during the current year far exceed the amount estimated at the close of last year, and compared favourably with the estimate.

MON. ACC. HELD BY THE COMPANY.—The interest has been well met, and considerable sums of principal have been repaid.

DEBENTURE DEBT.—This has been reduced during the year, and will be further reduced at the approaching term. Such renewals as were considered advisable were readily arranged at 4 and 4½ per cent.

1884-87	£4,886	11	1
1887-88	2,297	16	7

Total expended on Tea extension	...	£7,184	7	8

TEA CULTIVATION.—Indian tea now forms 50 per cent. of all the Tea used in the United Kingdom, whereas no longer ago than 1865, China furnished 97 per cent. According to an article in *Nature*, the Australians consume 81 oz. per head of the population, English people 73 oz., while the inhabitants of the United States come next with 21 oz., those of Russia, Belgium, Holland, and Denmark consume only from 7—8 oz per head of the population. Unfavourable contrasts are sometimes drawn between the services rendered by botany and botanists to the State, and those rendered by chemists and engineers. The botanists, however, can show a good record—Indian Tea, Cinchona, Cotton, India-rubber, Gutta-percha are all substances, the development, and, in some cases, the discovery of which was due to botanists, and their culture to horticulturists.—*Indian Tea Gazette*. [Who but botanists could discover, and who but horticulturists could cultivate new plants?—E.D. T. A.]

THE SECRETION FROM ROOTS.—Recent investigations on this subject undertaken by D. Hans Molisch have shown that the acid secretion from the roots of plants attacks organic even more powerfully than inorganic substances, not merely dissolving them, but causing in them important chemical changes. It exercises both a reducing and an oxidizing power. It stains guaiacum blue. It oxidizes tannin and humic substances, and hence, greatly promotes the decomposition of humus in the soil. It transforms cane-sugar into reducing sugar, and has a light diastatic action. Plates of ivory are corroded by it. The root behaves in many respects like a fungus, specially in the fact that the fungus alters the organic constituents of the soil by definite excretions, and causes their more rapid decomposition. This root secretion does not merely impregnate the epidermis, as has been generally supposed, but is often excreted over its surface in the form of drops.—*Indian Tea Gazette*.

ADAPTATION OF PLANTS TO RAIN AND DEW.—Professor N. Wille records in Oohn's *Beitrage zur Biologie der Pflanzen*, 1887, the results of a series of experiments for the purpose of determining the extent to which plants can absorb moisture through their leaves or other aerial organs. The experiments were made on a number of different plants by placing on the leaves drops of a 1 per cent solution of lithium chlorate, and then examining, by means of the spectroscopic, the extent to which the lithium was absorbed. The general results obtained were that water is absorbed so slowly, and in such small quantities, through these organs, in comparison to the amount taken up through the root, that it is without any physiological value to the plant. This applies equally to ordinary leaves, and to those which possess what have been regarded by some observers as organs specially constructed for the absorption of water.—*Indian Tea Gazette*.

CEYLON ESTATE ADVERTISED IN LONDON.—Ceylon.—For Sale.—Good opportunity for a Small Capitalist, or a Father wishing to Start his Son in Life.—A nice Tea Estate, in a healthy and favourite district; cart road adjoins the estate; the Kelani River runs almost at the foot of the estate boundary; splendid chances for extending; good bungalow, tea factory, tea rolling machinery, and cooly lines. Tea in bearing as follows: 64 acres, from 2-7 years old. Forest and Ohena 61 acres. Total 125 acres. Free. Crown title. Crop average 25,000 lb of tea. Price £2,500. Apply to C. F. Ross Wright, Labugama, Ceylon.—*Morning Post*.

"BLISTER BLIGHT": WHAT IS IT?—The following paragraph appears in the *South of India Observer*. Has any Ceylon tea planter had experience of the blight referred to? Is it due to insect or fungus, or purely chemical?—"We regret to hear from a correspondent of the occurrence of 'Blister Blight' on the tea plant. It is said to be seen on low and high land; on low and high pruned bushes; on bushes thoroughly cleared of all small twigs; where there is shade and where there is none; on young and old plants; on well and badly cultivated gardens; in rainy and fine weather; it is also to be seen on rich and poor soil; but it may be said to increase where there is a continuation of successive rain for a week or more."

NEW CALEDONIA.—The report just issued by Mr. Edgar Layard, Her Majesty's Consul at Noumea, upon the trade of New Caledonia for the past year, although to some extent incomplete and unsatisfactory, owing to the slipshod manner in which the French Colonial Bureau at Noumea issues its official statistical statements, contains some highly interesting facts. The Consul has had to take the figures as supplied to him, and Mr. Layard tersely explains the extraordinary confusion of the returns by observing that New Caledonia is a penal settlement first and a Colony afterwards, and that commerce holds a very secondary place in the estimation of the authorities. The effect of sending the heavily-subsidised Messageries steamers to New Caledonia has been to decrease the trade with the Australian Colonies, as the contracts are now executed in France. The French Government has given instructions that all orders for the supply of the convict establishments must for the future be executed at home.—*European Mail*, Oct. 12th.

DR. BURCK'S REMEDY FOR COFFEE LEAF DISEASE.—The *Soerabaia-Courant* of October 17th contains an extract from *De Landbouwer*, a translation of which is as follows:—"The Coffee-Doctor.—Dr. Burck, or the *toean doctor koppie*, as the natives of the Smeroe at once named him, is at present making an experiment with his pricking method in the Toeren district, Malang division. He is also visiting a single private estate. We have learnt from a good source that Dr. B. was delighted when he saw the fine private plantations here in the Oosthoek. In Mid-Java they do not know such trees, he said. [A note is appended to this, as follows:—"No longer at present perhaps, though we believe that a single good estate is still to be found also there, in the *high lands*. But five years ago the finest estates were still to be found in Mid-Java."] Dr. B. still continues to speak confidently of his repressive method, and explained to the planters that one woman can sprinkle three bouws during one month. Only the third pair of leaves, however, must be operated on, and Dr. B. maintains that in this manner a pair of leaves can be prepared each month, so that the tops of the branches do not die, the fruits ripen, in a word the object is attained. He had not yet been able to find a suitable pulverizer for his preventive method. We learn further that the pulverizer of Mr. D. de Waal has not given satisfaction at Buitenzorg."

PLANTING REPORTS FROM THE HILL-COUNTRY OF CEYLON:

AUSTRALIAN EUCALYPTS AND ACACIAS—RAILWAY SLEEPERS: SOFT vs. HARD WOOD.

Colombo, Nov. 12th.

In writing about the eucalypts of Australia as suitable for re-afforesting our high altitude jungles, I might have added that the red gums (there are several, but eminently the common *E. rostrata*), make excellent railway sleepers. About the singular and numerous family of "gums," there is an immense mass of interesting information, couched occasionally in curious idioms in Baron F. von Mueller's elaborate and splendidly illustrated *Eucalyptographia*. Possessing and valuing this work, I wrote to ask if there was a similar publication in regard to the great family of Australian acacias. In response I received the first seven decades of Baron von Mueller's "Iconography of Australian Species of Acacia." The well chosen motto is "SED GAUDEBIS ET EXULTABIS USQUE AD SEMPERITERNUM IN HIS, QUE DEUS CREABAT.—*Prophetia Isaiæ LXV, 18.*" [But be ye glad and rejoice forever in that which I create.] After the ample information, popular as well as scientific, afforded by the Victorian Botanist regarding the eucalypts, the work on acacias was to me a great disappointment. The illustrations, it is true, are all that could be desired, faithful and beautifully executed, but not only are the descriptions purely and technically botanical, but the Baron avows that his object was to depict those species of native acacias of which no drawings had previously appeared anywhere. Hence we look in vain for portraits of the species which have become familiar to us here in Ceylon, as well as for indications of the economical uses or suitability for cultivation of the species actually dealt with. The following is a specimen of the information afforded:—"ACACIA CONTINGA. Bentham, Flora Australiensis, ii 322 (1864) 1, part of a branchlet. 2, flower head. 3, bracts. 4, unexpanded flower. 5, expanding flower. 6, longitudinal section of a flower. 7, front- and back-view of a stamen. 8, pollen grains. 9, pistil. 10, lower portion of a fruit valve with seeds. 11, a seed separated. 12, transverse section of a seed. 13 and 14, longitudinal sections of seeds.—All enlarged, but to various extent." In some cases there are botanical details, such as, "phyllodia, part of a phyllodium;" and so forth. For botanical identification, and I may add for identification by intelligent observers who may not call themselves botanists, nothing could be more perfect than the detailed drawings and the descriptions, but for popular accounts of the species we must resort to other volumes. The grand feature in von Mueller's *Eucalyptographia* was the combination of equally full botanical and general information, (quality of timber, suitability for firewood or charcoal, richness in gum, essential oil, &c.) face to face with the portrait plates and the botanical details. The species of acacias in Australia appear to be more numerous than even the eucalypts. In his penance von Mueller speaks of at least 400 acacias! But a couple of extracts from the introduction will be interesting:—

"Through the liberality of the Victorian Government it became possible, to prepare in the Phytod. Department of Melbourne successively several volumes, descriptive of some portions of the Australian Flora. Thus in earlier years appeared a series of lithographs in illustration mainly of orders and genera of Victorian plants; in latter years an almost complete iconography of the Eucalypts of Australia became elaborated, and this was followed quite recently by an Atlas of Myrtaceous plants. In a desire of continuing these

pictorial issues it was deemed best, to devote the next volume to those native species of Acacia, of which hitherto no drawings had appeared anywhere. As the genus Acacia is by far the largest in the Flora of this part of the globe, numbering more than 300 well-marked specific forms, hardly one-third of them hitherto illustrated anywhere, much difficulty was experienced by horticulturists and artisans, here as well as abroad, to identify with systematic accuracy any particular kinds of these plants, either cultivated for ornamental purposes or drawn into use for technic objects, so that a work like the present one seemed specially called for. Moreover it appeared likely, that by offering additional means for naming any of the numerous Acacias of ours now known, they might become restored in European Conservatories to that favor, which they enjoyed so much in the earlier part of this century, when they were largely reared as the first harbingers of the spring, and were the objects of much admiration and delight for the profuseness of their flowering or for the oddity of their fantastic foliage. Since then various of the arborescent Acacias of Australia have attracted forestal attention very widely also in countries with mild climes on account of the celerity of their growth, or the technic importance of their wood, or the great value of their bark for the tanning industry, or the copious yield of mimosa-gum, so that this vast genus of plants is now surrounded by a multifarious practical interest, alien to it when but comparatively few of the species were known and the significance of many for technology remained unascertained. Indeed it may be readily foreseen, that through a publication, such as the present one, various branches of applied workmanship, including that of the seeds-trade, will become promoted or benefited.

"A work of this kind ought to have some bearing on our educational efforts likewise, as by its dispersion through the Australian dominions, not merely as patterns for drawing or as text for some phytologic glossology, but also as easy means for directing pleasurable the attention of residents all over Australia to some of the leading features of the floral world near them, and this perhaps far through the next century, when our rich-blooming or curious or fragrant Acacias, while they have become widely naturalized elsewhere, will no longer extend in their gayness and loveliness over all the vast pristine spaces occupied by them now!"

The materials for the plates, it is stated, have been accumulating for forty years. The drawings show diversities of forms in leafage and especially in the seed pods, comparable to the vagaries of the orchid tribe. Some of the leaves are extremely long and thin, others out of proportion broad, while others again are merely little angular bits ranged along the stalks. In some cases thorny spines predominate. The pods in many cases curl round like wheels, while in others they assume the serpentine form. One acacia is so like a heath that it is popularly known as the Australian heath, and its botanical name favours the idea. In the seven decades published the number of species figured and botanically described is no fewer than seventy, ten in each decade, so that, of course, 100 at least will be figured and described in the complete work. By means of the *Eucalyptographia*, from the detailed descriptions as well as the plates, a large number of the eucalypts growing on Abbotsford estate have been identified, including jarrah (*E. marginata*), *E. robusta*, stringy bark, &c. We have also some acacias, not yet identified, so truly magnificent in growth, that we cannot help thinking that many of the Australian acacias, beside those known to us, may be found valuable for railway sleepers as well as for general timber and firewood purposes, not to speak of tanning bark and fine gum, in which latter substance the gigantic trees we speak of are rich, the crystallized exudation being of a beautiful ruby tint.

As to the question of soft and hard wood sleepers for railway purposes, the impression prevails that the railway Department often prefer the soft

perfectly creosoted pine wood of Scandinavia mainly on the ground of superior elasticity. It was, I suppose, on some such ground that a quantity of hard-wood (doon) sleepers which Mr. Nowell meant to have used on the Nawalapitiya-Nanuoya section were rejected and compensation made to him? Residing as I do within a couple of hundred yards of the Colombo seaside railway, the quality and life-term of the Norwegian sleepers have engaged my special attention. I have constant proof before me in my "walks abroad," that the merit of elasticity in the soft-wood sleepers involves the serious demerit of liability to be crushed. In a great many cases, too, it becomes speedily evident that sleepers blackened with the creosoting process and solid looking on the outside are composed of white sap-wood internally, which soon decays from dry rot or some other form of "Eremacausis." The process of removing crushed or decayed sleepers has gone on for years at a rate calculated to give serious thought to an onlooker, and to suggest the idea that hard-wood sleepers—made from timber not only hard but calculated to resist the action of damp earth and broken gneiss, laterite or sand ballast—might be cheaper in the end, even if they cost twice or thrice the money to begin with. We have plenty of excellent timber trees in Ceylon, but, unfortunately, the mass of them are at such distances inland, with means of carriage so ineffective and expensive, that sleepers cannot be delivered where they are wanted at the railway price of R5 each. We actually want railway extension through the densely-forested regions of the north-west, north-central, northern and eastern portion of the island, to secure good sleepers for our railways. At present a considerable portion of the railway line near Colombo is bare of top ballast, and we suppose the experiment is being tried of ascertaining whether the sleepers will not last longer when fully exposed to atmospheric influences? Iron and steel sleepers are being increasingly used in India, and I suppose experiments have been made with metal sleepers in Ceylon. But for a long time yet, if not always, wooden sleepers will be in request, and especially hard wood sleepers. The deodar (Himalayan cedar) of India seems to be closely analogous in quality to the Norway pine, being soft and easily crushed and disintegrated, while *säl* (*Shorea robusta*), as a material for hard-wood sleepers, seems to occupy the same place on the Indian Continent that red-gum wood does in Australia. With deodar sleepers, it is asserted in an article in the *Indian Engineer*, correct gauge cannot be long maintained, and I suppose the same difficulty with Norway pine leads to the constant and expensive removals and renewals which I have seen for years (since the formation of the line, in fact) proceeding on the seaside line. From the article referred to, I make a suggestive extract:—

"From experiments made some years ago, it was found that curves of from 1,000 to 1,500 feet radius required to be re-spiked to gauge every six months—at least, when laid with deodar sleepers—and, in some cases, where the traffic was exceptionally heavy, the rails were half-an-inch wide to gauge three months after being laid with new sleepers. The same curves laid with good *säl* sleepers were only from one-eighth to one-quarter of an inch wide after two years' heavy wear; and where the traffic was ordinary, the gauge remained correct for over three years. This speaks for itself both as regards economy and safety.

"After many years' experience in railway working, and thoroughly examining the statistics compiled from time to time in Europe, America, and Australia, the writer can only confirm the opinion which he ex-

pressed nearly twenty years ago; that, for Indian Railways, no better wooden sleeper has ever been known, or is ever likely to be found, and that wherever the use of wood is desirable, or compulsory, only the best *Nepai säl* should be used. First cost is always a serious consideration; but it is high time that Railway Managers should know that cheap material is seldom, if ever, economical. Twenty-six years ago, with the exchange at two shillings per rupee, Sir A. M. Rendel expressed his opinion that it was cheaper to pay R5-8-0 for *säl* sleepers than to import creosoted firs, and that it would pay better to give R6 each for *säl* sleepers than to import iron bowl sleepers from Europe. If this was the case in 1862, what can be said now with the exchange at 1s 4½d per rupee."

The creosoted pine sleepers, discarded after a few years' use, realize nothing or next to it, while hard-wood sleepers of good quality after a service of a score or more of years would still have an appreciable selling value. The objection to Australian jarrah sleepers was their liability to split, but we should think that a proper mode of seasoning (perhaps in water?) would obviate this difficulty. Col. Clarke in his late report, it will be remembered, indicated the large and prevalent kumbuk tree as a material for sleepers and we trust the timber of this magnificent tree may be so utilized. Some, at least, of our many hard-wood trees ought to be found suitable in quality and cost. To quote again:—

"From tests made with different descriptions of sleepers at Boston, in 1886, it was found that hard-wood sleepers at one dollar to 1½ dollar each were cheaper than soft wood sleepers at from 50 to 75 cents each.

"Concerning the experiment Mr. Sargent says:— 'None of the ties which have been removed from the track were decayed, with the exception of the *salantus* taken out in November, 1882, and this stick was defective and partly decayed when laid down. The other ties, when taken out, have been worn out by pressure, and not by decay. The whole mass of wood directly under the rail has been so crushed and disintegrated to the depth of the spike holes (5½ in.), that the spikes have no hold upon the tie, which has to be abandoned. The experiment, if it has done nothing else, has confirmed the opinion of the most experienced Railway Engineers, that ties do not rot out, and, therefore, ability to resist decay in contact with the soil, is a less important quality in a wood to be used for this purpose, than ability to resist a direct crushing and wearing pressure."

The following confirms my own observation in regard to pine sleepers on the seaside line:—

"In addition to the crushing of soft wood sleepers complained of in America, creosoted fir sleepers in this country, are subject to a dry rot internally. It is nothing uncommon to find sleepers of this class quite hollow inside, although from outward appearances, they would be passed as sound, first-class, sleepers. Experienced men have often been deceived in this way, and although no reason has been given for this rapid deterioration which it appears has not been found to exist on English Railways, it is, no doubt, a source of danger in India on account of the difficulty of detecting it."

The summing up of the article by "Railroader" in the *Indian Engineer* is as follows:—

The advantages to be gained by the use of *säl* or any other similar sleeper, may be summarized as follows:—

- (1.) Less danger from fire.
- (2.) Correct gauge.
- (3.) Smooth road in consequence of less renewals.
- (4.) Fewer thefts of spikes.
- (5.) Reduced cost of maintenance.

The four first-mentioned, not only represent less danger from accidents—and it must be remembered that a very slight accident often costs from R10,000 to R15,000—but the 2nd, and 3rd, also mean less wear and tear of both rolling stock and permanent-

way material, and consequently important reductions in the yearly working expenses. In fact, as in all other matters pertaining to Permanent-way, the best is the cheapest in the end.

I may add that soon after the railway was laid on the seashore I saw sleepers taken up which were swarming with white-ants, but for years back I have seen no trace of these destructive insects on the line. Added to the reverberations from frequent trains, gangs of coolies are constantly disturbing and re-settling the ballast. So much about soft and hard wood railway sleepers, for the present.

CEYLON UPCOUNTRY PLANTING REPORT:

PLANTERS AND MACHINISTS: THE NEED OF PLAIN INSTRUCTIONS—*C.g.*, FOR MR. DAVIDSON'S "SIROCCO"—THE SCHOOLMASTER ABROAD—NEW COOLIES AND NEW WAYS—TEA SEED WANTED IN UVA—TEA SEED IN HUSK—"ALL ABOUT TOBACCO" MANUAL.

13th November 1888.

Some planters like to have tradesmen about, and some don't: I fancy there are more of the latter than the former; for the worry that carpenters and masons give, has, I believe, shortened the lives of most of us. How we affect their lives is another question, and need not be discussed here, except to say, that if they can assimilate and utilize half of the energy which is expended on them when they have fairly roused us, they should in time become changed characters, and more of a credit than they are at present. If Mr. Davidson of the "Sirocco" fame knew how much we have to suffer already, I think he would have been more careful in the drawings that are sent out with the instructions for erecting his Driers. These drawings are a snare and a delusion, and the amount of inconvenience and extra work they have caused are a source of considerable complaint. The drawings of the side view and end view do not correspond, and the figures given for the depth of the pit are not according to scale. When the figures given and the depth shown are taken as a guide for other measurements the result is a pit which does not suit your "Sirocco," but into which you may actually fall and metaphorically do fall. Now for a man to dig a pit, and himself fall into it, is a state of things which we have the highest sanction for regarding as aggravating in the extreme and leading to no good. In fact only got up hand-sets are all very well; but if the information therein contained is inaccurate, and gives a busy man more trouble than he need have, let exactness take the place of ornamentation, and let our way be plain. Scholastic advertisements ought to be above suspicion in the matter of grammar. For some time back there has appeared in your columns a notice referring to education for Ceylon boys, in which there is the following unhappy sentence:—"Mr. (and Mrs.) — would superintend *their* boarders' home studies and treat them as *his* own children." When the schoolmaster goes abroad for pupils, it were well if he were not quite so much abroad himself.

Some new coolies were introduced to an estate lately. They had formerly been employed in the French island of Réunion, and when they arrived in Ceylon everything was new to them. Why they came here I do not know, for they had no connections; unless it be that they had heard that money was to be made on tea estates, and that the Indian Government had prohibited the Indian emigrant coolies from proceeding to the French Settlements. Anyhow their advent at the Government colony lines caused quite a commotion; kaddie-keepers,

kanganies, and others were anxious to get them, for forty-six coolies, owing nothing, were clearly a mine of wealth. A number were enticed away, and it is of the remainder that I would write. When they reached the estate they settled down, and in doing so have quite unsettled the conductor. Their home is far afield from the usual recruiting ground of the Tamil kangani; their language is not Tamil; and several of them know a little French. The men dress in loose trousers, with a shirt and coat, while the women have cotton print gowns. Old Soodin the conductor deems it an affront that these labourers should call an alavanga by any other name; all their peculiarities he indeed resents; but the climax of their audacity he felt had been reached, when he discovered that they ate their rice with spoons! It was then he came to his master, and seeing perhaps an expression of incredulity on his face when the spoons were mentioned, he emphasized his statement with the words "I saw them."

Those who are selling tea seed have, I am told, a good market at present on the Badulla side. One estate I know, which has a name both for its tea and for its seed, is booked up for some time to come with Badulla orders. Prices of course are not so high as they were a couple of years ago, but, even at present rates, seed orders are remunerative.

An estate in the lowcountry, that is out of the way, and has in consequence a considerable distance to be covered ere supplies reach it, was a little unfortunate at times with the seed sent down. An effort has lately been made to overcome this difficulty by having the seed dispatched in its natural husk, with I understand the happiest of results. The seed arrives almost as fresh as if taken from the trees, and the extra weight carried is as nothing compared to the advantages gained. Perhaps if Indian seed were sent in this way the failures so often deplored, might be materially decreased.

I am glad to hear that in your new Manual, "All About Tobacco," the brochure in *Ms.* which I mentioned some months ago, as being so full of information on that new product, and as likely to be published, is to be incorporated in your book. What with that, and wrinkles which can be got elsewhere, the budding tobacco grower, who at present is searching about pretty much for information, will feel, when your book is in his hand, as if he had got on the right side of the secret society. I have no fear whatever, if a few score of intelligent Ceylon planters go into tobacco, but that the result will be success, and this success should be more easily attainable, when they have the right methods of curing explained to them, and experience only wanting. In that day the tobacco esoteric circle will evaporate: the "cock in their beaver" will disappear: indeed, I should not be surprised, if, in sheer shamefacedness, they do not use their "beaver" to extinguish themselves.

PEPPERCORNS.

INTERESTING ITEMS ABOUT INDIA.

The following extract from a Calcutta letter, sent by one of the correspondents, is interesting, and clearly demonstrates that manufacturers in England have great difficulty in competing with Bombay spinners:—"As a matter of curiosity we send you under separate cover a knot of yarn, which is one of thirty comprising a bundle of a local spinning, lately brought to us from the bazaar. The 30 knots made up a bundle of 8½ lb., which was sold as 'light 30's.' The yarn really is 20's or 21's, and is so short reeled that the knots, instead of cou-

taining 10 hanks, contain less than six, though these six are divided into 10 skeins, and each skein into seven divisions by the tie. The bundle actually contained 173½ hanks of 20's or 21's, made up to resemble 300 hanks of 30's. Strange to say, there is a very strong demand for this deceptively packed yarn, and it fetches 9 pies per lb. more than it would do if it were honestly bundled as 20's. We shall be glad to know what the Merchandise Marks Act would have to say about such yarn in England. The bundle had no ticket or stamp upon it, but we have seen another bundle of the same spinning which bore a ticket with the words "light 20's" on it, and which contained 127½ hanks of 17's made up to resemble 200 hanks of 20's."

The following table, compiled from the 90th table in the New Indian Statistical Abstract, shows the growth in the export of the principal Indian staples during the past ten years. It will be understood that they refer solely to the sea borne, and not to the trans-frontier trade:—

Articles.	Exports, in Millions of Rupees.	
	1878.	1887.
Raw cotton	93·8	134·7
Opium	123·7	110·7
Seeds	73·6	92·2
Rice	69·5	88·3
Wheat	28·7	36·2
Hides and skins	37·5	51·4
Tea	30·6	48·8
Raw jute	35·1	48·0
Manufactured jute	7·7	11·5
Indigo	34·9	36·9
Cotton twist and yarn...	7·4	34·1
Cotton manufactures ...	15·5	24·3
Raw wool	9·6	13·4
Coffee	13·4	15·1

Of the 34 articles of which the figures are given in the abstract, only nine show a decrease, and of these the only one of first-rate importance is opium. On the whole, the exports increased from 651·8 million rupees in 1878 to 884·2 in 1887, and they have never been so great as in the latter year.

Mr. Heneker Heaton, writing to *The Times* on the subject of cheap postage to Australia, says:—"In May, 1887, I was able to announce in *The Times* that a 3d. rate for Australian letters would be conceded. I have since received (on Jan. 31st 1888) a written assurance from the Postmaster-General on the subject, and the Postmaster-General of New South Wales and several Agents-General also promised their support or openly favoured the scheme. This morning I am informed that the postage will be 4d. instead of 3d. for the ocean-borne letters to Australia. I strongly denounce this charge as being most unsatisfactory to the public. Threepence is a convenient charge in itself; the man with many letters to write or few sixpences to spend being able to send two letters to Australia for 6d. instead of one, would not be likely to forget the boon. The threepenny bit, too, still circulates, and the fourpenny is doomed. The 3d. rate would be accepted as a real instalment by itself and others. But Mr. Raikes should clearly understand that we would prefer to wait rather than accept the 4d. rate."—*H. & C. Mail*, Oct. 26th.

PLANTING AND AGRICULTURAL PROSPECTS IN THE GALLE DISTRICT.

A well-informed correspondent writes as follows:—"I have observed some extensive tracts of Crown land in Hinidum Pattu, connected with the Matara district, in the Southern Province, which are well adapted for tea and coconut cultivation, in case Government decides to offer them for sale. In addition to the excellent soil (of which there is abundant proof in the exuberant vegetation), precious stones, principally

catseyes, are found in both high and low lands. There are also very valuable timber forests. The present Government Agent of the Province, than whom no one has better experience of the country, has been instrumental in opening a minor road to connect Hinidum Pattu with the Matara district. It will join the principal road on the Morawak Korale line at the 32nd mile-post, and intersect the Crown lands above-mentioned. The distance is only 7½ miles from Opata to Debigaspe and the junction is 9 miles from the Akuressa resthouse. The cutting of the line is in progress; on completion it will be necessary to improve the existing bridlepath through Habarakada to Hinidum as to admit of wheeled traffic. It will be a better road, and involve less expenditure, than the line through Udugama, as the construction of bridges on the latter will make it costly. When I was last at Hinidum Pattu the villagers frequently complained that they had been reduced to great poverty since the abolition of chena cultivation in that part of the country, and expressed themselves willing to pay Government Rs250 per acre annually if they were allowed this privilege, explaining that the yield of paddy on low lands was very unremunerative. I witnessed several cases of fever in the Hinidum Pattu during my visit. The native practitioners prescribed some powders (not quinine), allowing the patients to partake freely of curds, coconut water, &c.: strange to say most of them recovered."

TEA IN TRAVANCORE.

When the European planters in Travancore lost heavily in coffee they were compelled to put their land to other uses, and so took to the cultivation of tea, encouraged by the total remission of tax conceded by the Government of the Maharajah, and by the large grants made for roads, which had fallen into disrepair when the planters were not in a position to maintain them. Thus fostered, tea planting is becoming a thriving industry in the State, and the produce competes well in the market with the teas grown in older settlements, 935 cwt. of tea were exported from Travancore in 1886 and 1,567 cwt. in 1887. From the hills the plants strayed into the plains, where they grew luxuriantly, showing that the low country was adapted to their cultivation as well as the hills. The Travancore Government was not slow to take advantage of this circumstance to benefit the people. The Dewan recently issued a proclamation offering waste-land in the low country free of tax for a few years, and thereafter at a low assessment, to natives disposed to take to the planting of tea in small plots. The plan apparently is to tempt the European capitalist to open up estates in convenient localities in the plains by giving him, on easy terms, a few hundred acres here and there where the native can learn how to cultivate tea, and where he can find a factory which will buy his raw produce for manipulation and export; for, as yet the native is neither rich nor expert enough to establish factories of his own and go into the manipulation business. Two of the most experienced planters of Peermaad have sent in applications for land in the low country.—*M. Mail*.

DRUG TRADE REPORT.

LONDON, Oct. 25.

CINCHONA.—At the fortnightly auctions on Tuesday a fair average quantity was offered, the catalogues comprising:—Of—

	Packages.	Packages.
Ceylon bark	... 1,857...	of which...1,391 were sold.
East India	... 302...	" ... 254 "
Java	... 245...	" ... 245 "
South American	... 1,210...	" ... 356 "
African West Coast	10...	" ... "
Total	... 3,624	2,226 "

The auctions proceeded rather slowly, and in the beginning several parcels sold below the valuation; subsequently the tone improved somewhat, only to flag again towards the close. A number of parcels

were bought in, the limits not being obtainable, for others the holders seemed to meet the market. The result of the sales leave the article slightly weaker, although not perhaps to a quotable extent, and the unit value may be placed at 1 1/4. The following are the approximate quantities purchased by the principal manufacturers and agents:—

	Lb.
Agents for Messrs. Böhringer & Sons ...	118,855
" the American and French works ...	112,686
" the Auerbach works ...	107,161
Messrs. Howards & Sons ...	47,723
Agents for the Brunswick works ...	35,304
" Messrs. Zimmer & Co. ...	35,304
Mr. Thos. Whiffen ...	10,610
Sundry buyers ...	8,265
Quantity sold ...	497,519
Bought in or withdrawn ...	225,246

Total offered ... 722,765

SOUTH AMERICAN BARK.—The supply consisted mainly of Calisaya quills from the Bolivian plantations, of which 297 packages sold at 11d to 1s 1d. per lb. for good stout to bold silvery quill, and at 6d to 11d for more broken and damaged lots. For 117 bales Soft Colombian bark 4d was refused, the price being 3d per lb. more. Of 11 bales new Carthagena, part sold at 4 1/2d for sound, and 4d for damaged. Uprea in good supply, but mostly bought in; 64 bales of new import (via Havre) are limited at 6d per lb. but only 3d was offered. Thirty packages very common, imported in 1883, sold at 3d per lb.* A parcel of common red bark was bought in, from 1s 1d to 1s 6d being asked for the best lots.

CAYLON AND EAST INDIA BARK.—The following prices were realised: Succirubra, dust 1 1/2d to 2d.; branch, 1 1/2d to 3 1/2d.; chips, small and weak mixed to good stem, 1 1/2d to 5d.; spoke shavings, dull to fine, 2 1/2d to 6d.; root, 2d to 4d; renewed shavings, coarse to fine rich 2d to 1 1/2d.; quill fair silvery, 6d. Officialis, branch, 2 1/2d to 3d.; chips, mostly mixed with branch, &c. 3d to 1 1/2d.; spoke shavings, 3d to 6d.; root, 6d to 8 1/2d. Hybrid, &c. chips, mixed to good, 2d to 6d.; spoke shavings, 2 1/2d to 1 1/2d.; root, 6d to 6 1/2d.; renewed fair to fine, 5d to 9 1/2d.

JAVA BARK.—The on fire supply, consisting mostly of Ledgeriana bark sold at 3d to 9d for medium to fine sound stem chips; 2d to 1 1/2d for damaged ditto, root 1 1/2d to 1 1/2d, dust 3d to 9d, on 1st reaching 1s 2d per lb., the highest price paid for any bark at the auctions. Achen West Coast Bark 10 bales—total 1,120 lb.—dull thin quill of "green" character, sea and oil damaged were brought in at 11 per lb., no bids being made. The parcel was imported from or via the Island of St. Thomas.

CHINA.—The German manufacturers report a somewhat better enquiry, but prices have not been altered, and there does not seem much prospect of a change.

CHINA.—The quotations are nominally unchanged. Nineteen bags were imported here per "Dorchester," 3 bags per "Patriotus," and 4 bags per "Glaucus"—all from Singapore.

QUININE.—Towards the end of last week sales of about 15,000 oz. second-hand quinine (Auerbach, J. & Co., and F. Lombardi brands) are said to have been made on the spot at 1s 1/4 per oz. The manufacturers are said to have sold scarcely anything until today, when a run of 20,000 lb. quinine, March delivery, were sold by the agents at 1 1/2d per oz. The B. & S. agents have advanced their quotations from 1s 11 to 1s 1 1/2d for December, and 1s 1 1/4 for February delivery. About 200,000 lb. quinine is quoted at 1s 1 1/2d to 1s 1 1/4 per oz. respectively.

CHINA.—On 12th inst. 100 bags of quinine Caylon (German chips, renewed left wing) and at auction at 2 1/2d per lb. In Ceylon a daily trade has been done at

* One halfpenny per lb. What with cost of production, freight, charges and interest on capital, there must have been a loss of fully 1s. per lb. on this lot. —Ed.

8 1/2d in the begining of the week, but subsequently at an advance, spot and forward delivery, closing at up to 8 1/2d per lb. None were offered at the auctions. Trade in Ginger remains exceedingly quiet, and the only sales made at the auctions consisted of a quantity of small to bald, cut, wormy Cochin at 24s 6d to 42s, and Jamaica, fair Bhatoo at 56s, and medium up to 68s per cwt. Mace is obtainable at lower rates ordinary to good red Penang 2s 4d to 2s 7d; West India 2s 3d to 2s 5d; good bright wild Bombay 9 1/2d to 9 3/4d per lb. Nutmegs dull and tending lower. Sales have been made of Penangs (67's to 151's) at 3s 5 1/2d to 1s 9d per lb., and West Indian (90's to 127's) at 2s 4d to 1s 11d per lb. Pepper, black dull, with very little business. Pepper, white has declined to 11d for fair Penang, Pimento animated, and still rising at the auctions; 3 1/2d to 3 3/4d per lb. was paid for fair Jamaica, but since then 3 7-16ths d. to 3 1/2d per lb. has been conceded.

THE DUTCH MARKET.

AMSTERDAM, October 24th.

CINCHONA.—The next public sales will take place on November 8th, and will contain 257 cases and 1,395 bales Java bark, consisting of about 97 ton manufacturers' bark and about 31 tons druggists' bark or: Ledgeriana, quills 64 cases; broken quills and chips, 24 cases 866 bales; root, 302 bales; Officialis, broken quills and chips, 54 bales; Schuckkraft, broken quills and chips, 58 bales; Caloptera, quills 9 cases; Hybrids, broken quills and Chips, 10 cases 6 bales; Succirubra, quills, 150 cases; broken quills and chips 76 bales; root, 33 bales—total 257 cases 1,395 bales. Of these 1,654 packages, 24 cases and 609 bales were imported by the Netherlands Trading Company for account of the Government. The total quantity offered contains the equivalent of about 172,800 oz. quinine sulphate.—*Chemist and Druggist*, Oct. 27th.

SULPHIDE OF POTASH.—An American contemporary gives the following particulars of a successful experiment with sulphide of potash in the suppression of mildew on roses. It says:—"A stock of some 2,000 young rose plants become infested with mildew to such an extent that their leaves were curled up as if quite withered showing only a dull grey. No green surface appeared on all the foliage. They were treated to sulphide of potash a quarter of an ounce to a gallon of water, syringed with a very fine rose. In the morning the remedy was applied again and the plants kept close. Before night nearly all the plants had expanded their foliage, and the fungus was evidently destroyed. They were then syringed with clear water and have since made a good growth."—*Indian Agriculturist*.

QUININE IN CHOLERA AND FEVER.—The following hints may perhaps be useful to Planters in most parts of India:—*Dorcan Times*, on the authority of Dr. Lawrie, the Residency Surgeon, Hyderabad, says that a preventive for cholera has been found in quinine: "While the disease is about, every one ought to take from 3 to 5 grains of it before each meal. No one who does this, Dr. Lawrie is persuaded, will take the disease." A correspondent of a contemporary asks how quinine ever been brought forward in this light before? With regard to the articles which have been appearing lately about "heroic doses" of quinine, I may mention that five years ago when about to leave home for this country, my brother, who was not then commencing to practise as a medical man, told me to disregard the advice of old men, and urged me to take 3 to 5 grain doses, the proper thing, he said, was to take as much as was possible without permanently injuring oneself, say 30 to 40 grains, and then retire to bed, making up one's mind for a couple of hours, getting freshened, and leaving it to the Lord. When I have symptoms of cholera, and have some fear of it, I find that a powerful dose of quinine, I have found the treatment will cure me myself and on another small dose we both take as a preventive only.—*London Led Gazette*.

Surely all prices under 5d. left a loss?—Ed.

Correspondence.

To the Editor.

CEYLON AND INDIAN TEAS.

Peermaud, 2nd Nov. 1888.

SIR,—I send an advertisement cutting from a home paper, from which you will observe the light in which Ceylon and Indian teas are regarded and represented by certain dealers.—Yours faithfully,
D. M.

[The advertisement referred to, from a Scottish Highland paper, says:—"It is well known that this quality of souchong and the finest monings have for many years been shipped to Russia, thence the introduction in many cases by British merchants of somewhat doubtful quality of Assams and subsequently Ceylons. Assams and Ceylons have found more or less favour of late in this Country, owing to the absence of finest China teas. The subscriber holds a stock of teas varying from 1s 3d per lb., up to the price of his direct importation of souchong 3s 9d per lb."—Ed.]

INDIAN TEA EXPORTS.

Indian Tea Association, Chamber of Commerce
Calcutta, 3rd Nov. 1888.

DEAR SIR,—In their circular of the 14th April last the General Committee gave an estimate of the outturn of the present Season's Crop of Indian Tea based upon the following figures which they had been able to collect:—

ORIGINAL ESTIMATE OF CROP OF 1888.
Estimated Outturn of
Crop of 1888.

Assam	...	40,432,979
Cachar and Sylhet	...	30,542,905
Darjeeling, Terai and Dooars	...	17,222,468
Chittagong and Chota-Nagpore	...	1,630,960
Dehra Doon, Kumaon and Kangra	...	4,000,000
Private and Native Gardens	...	2,000,000
		95,829,312

From figures which have since been obtained a revised estimate has been prepared, based upon actual results to the 30th September, as follows:—

	Manufactured to 30th Sept. 1887.	Manufactured to 30th Sept. 1888.
	lb.	lb.
Assam	27,375,978	30,645,941
Cachar and Sylhet	19,690,863	19,444,086
Darjeeling, Terai and Dooars	11,672,722	14,602,295
Chittagong and Chota-Nagpore	972,415	961,623
	59,711,978	65,653,945

REVISED ESTIMATE OF CROP OF 1888:

Assam	...	41,869,654
Cachar and Sylhet	...	28,731,581
Darjeeling, Terai and Dooars	...	17,808,714
Chittagong and Chota-Nagpore	...	1,348,379
Dehra Doon, Kumaon and Kangra	...	4,000,000
Private and Native Gardens	...	2,000,000
		95,758,228

It will be seen from these figures that while the estimates for Assam and Darjeeling, Terai, and Chota-Nagpore, are increased by about two million lb., those for Cachar and Sylhet, and for Chittagong and Chota-Nagpore, are induced by the same number of lb., so that there is hardly any difference on the whole between the original and revised estimates.

The Exports to Australia, America, and other places during the past season amounted to 3,544,790 lb., and if this quantity, together with the requirements of Northern India, calculated at

1½ million lb. be deducted from the estimate, there would remain about 90½ million lb. for shipment to Great Britain during the season of 1888, but looking at the fact that the figures collected by the Association are generally short of the actual results it is probable that the present season's shipments to the United Kingdom will total 92 millions.—
Yours faithfully,
G. M. BARTON,
Assistant Secretary.

CINCHONA.

SIR,—Can any of your Planter Subscribers verify the annexed table on Cinchona Barks? It appears to be a very good return if true.

	Yield per ton Shavings.		Yield per acre Shavings.	
	At 4 years.	At 7 years.	At 4 years.	At 7 years.
	oz.	oz.	lb.	lb.
Succirubra oz...	5	1'25	14	2'25
Officialis "...	3	2'25	3	3'50
Robusta "...	5½	2'00	14	3'50
Ledgeriana "...	5	6'00	12	3'00
Ooty, 25th Oct.				L. W. G.

[The above table looks very businesslike and compact, but is really very misleading: An "acre" may be anything in cinchona planting: from 500 to 1,000 or 2,000 trees. Again "per ton shavings" must be a misprint for "tree" and "shavings" ought to be printed above the 4 and 7 years. We do not think that statistics have been kept in Ceylon so carefully as to verify these calculations in the form in which they stand: 1 lb. or 16 ounces dry bark per tree at 7 years' old has been obtained in Ceylon from succirubra and Robusta.—Ed.]

COFFEE AND TEA DOING WELL IN THE AGRAPATANA DIVISION OF DIMBULA.

Balmoral, Agrapatana, 10th Nov. 1888.

DEAR SIR,—Noticing in your London correspondent's letters remarks re the continued good quality of Ceylon plantation coffee, I send you by today's post a sample of what the coffee estates still cultivated on the Agrapatanas are producing this season. This is not a picked sample, but merely a handful brought from the heap by my conductor to show me what like it was, as I am confined to my room at present by sickness.

To show you what tea is going to do on the Agras, the writer has about 100 acres in full bearing, about 100 partially in bearing, and 100 just beginning to bear, and the daily gathering from this is over 2,000 lb. green leaf.—Yours faithfully,
R. B. LAWRENCE.

[The sample looks well: an expert pronounces it, "if ready for delivery as worth R12-25 if the quantity be 500 bushels or upwards. For 250 bushels and under R12-12½. The beans are not so perfect as the appearance of the parchment would lead one to expect."—Ed.]

CINNAMON PLANTING AND THE RETURNS IN CEYLON.

12th November 1888.

DEAR SIR,—I read with pleasure and interest your Siyane Korale correspondent's letters, though not always agreeing with his views upon agricultural matters. He is usually careful in his figures and quotations; but in his letter of the "End of October 1888," appearing in your issue of the 8th instant, he transgresses in this particular. Writing on the subject of Cinnamon he quotes figures from the "Planting Molesworth" as given he says by "two old planters"; and after making liberal deductions from the rates for cost of different works, he forms an estimate of what it would cost to produce a bale, or the expenditure on the upkeep of an estate per acre, the yield being taken at 100 lb. or one bale,

and then asks how is cinnamon made to pay when it sells for R4 per bale less than it costs to produce it? Truly this is a tough problem, and one I am glad to say I have not yet been called upon to solve in my experience, though I must admit that it has been, and is still, a puzzle to me as to how some estates manage to make expenditure and income meet. Partial abandonment, no expenditure except on preparation, and taking what nature gives under such conditions, is the solution to some; but this is at the cost of the steady ruin of the property and less income each year. Your correspondent a short while ago, in replying to a trenchant attack made on him by his Hapitigam rival, twitted him with misquoting his words, and of setting up a "man in buckram" that he might have the satisfaction of knocking him down. There is an old axiom to this effect: "People who live in glass houses should not throw stones." I said above that your correspondent gets his figures by mixing those given by the "two old planters;" this I object to as it is not fair to either. "Another Old Planter," in Notes on Cinnamon in your "Planting Molesworth," had left cinnamon planting for over a decade; he gives the cost of works at that time when probably owing to good prices and better yield, a few rupees extra of expenditure per bale was not thought much of: it is very different now, and you may remember that I sent you a few Notes on this subject shortly after the appearance of the "Planting Molesworth." Where does your correspondent get his information that superintendence is put down at from R12 to R15 per acre? Certainly not from the notes of "An Old Planter;" there he will find that the "cost of upkeep, including superintendence, is given at R13 to R15 per acre,—a very different thing to that sum being put down to superintendence alone. It may interest your correspondent to know that superintendence, weeding and pruning on the estate "An Old Planter" manages, does not cost R12 per acre; and he is vain enough to think that there are few estates kept in better order! I do not think that either of the "two old planters" would "look askance" at your correspondent for saying that "on a well-cultivated and well-managed estate the yield will be more than a bale per acre, and the expenditure less than the figures quoted." If he will kindly look at the Notes of "An Old Planter" he will then read: "Crop per acre 150 lb. quill bark, old estates with many vacancies will not give more than 100 lb. per acre." I think your correspondent would hardly venture to estimate more than this. What handicaps so many of the old estates is the large number of vacancies; and it is a hopeless task trying to supply these, particularly when the soil is very sandy. A proprietor who owns an estate that yields 150 lb. quill bark per acre is a lucky individual, and should make a fair profit annually. I quite agree with your correspondent when he says "anyway the profit from a cinnamon estate in these days of low prices is out very fine, and is hardly discernible." I am afraid the valuation of R300 per acre is much too high; the first value of an estate commonly be arrives at by taking the average yearly profit, after allowing for proper upkeep and cultivation, and allowing ten years in which to pay off the purchase money. The only remedy for the low price of cinnamon is the discontinuance of preparing chips; almost all the cinnamon property in the island is in the hands of natives, and if large owners would combine and agree, the matter would be settled at once. It is hopeless however to expect this; they have no confidence in each other to believe that the terms of such an agreement would be honourably carried out.—Yours truly,

AN OLD PLANTER.

CINNAMON PLANTING AND THE COST OF WORK.

S. YANE KONAIE, 17th S. V. 1888.

DEAR SIR,—In mixing up the figures of two "old planters" I have done your correspondent an injustice. I crave his pardon. It was unintentional. I must apologise to your correspondent for having unintentionally

credited him with giving R13 to R15 for superintendence alone. It does interest one to know that superintendence, weeding, and pruning cost R12 per acre on the estate your correspondent manages. It certainly shows careful and intelligent supervision. But is not the good order of the property your correspondent manages, due as much to the nature of the soil as to careful management? And is not the cheapness of weeding due to the same cause? Let confidences be mutual. The property I manage is planted with coconut and cinnamon and crediting each product with half the superintendence, the cost of superintendence, weeding and pruning is R15 the acre, and yet I cannot say that my estate, at least the cinnamon, is in good order as regards cleanliness, the weeds keep growing at the backs of the weeders. So you see, in spite of higher expenditure, I cannot indulge in the proud boast of your correspondent. With crop at from a bale to a bale and a half per acre, all I have to say is that if it is meant as a general average it is too high. I have known an old estate, as old as the one your correspondent manages, give two bales the acre once. That was many years ago and the figure has never been reached again. I also know a young estate with bushes not $\frac{1}{2}$ the diameter of the bushes on old estates, yield two bales the acre recently. I attribute it to exceptional causes, but I am confident it will yield two bales the acre again. But of course these figures are exceptional.

I am sorry your correspondent thinks my valuation of cinnamon land high, and yet only a few years ago a well-known estate in his neighbourhood changed hands at about three times my figure, and the purchaser was said to have made a profit by his purchase: "How have the mighty fallen."

I am glad to hear your correspondent thinks the remedy for low prices is the discontinuance of scraping chips. I have been always of this opinion and did my little best to bring about this desirable change, and have even gone so far as to give practical evidence of my belief by ceasing to scrape chips. I do not go with your correspondent and attribute the continuance of this suicidal system to native proprietors distrusting each other. Men of intelligence and position have been spoken to and they cannot see, because they will not, that the contemptible sum above cast they get for their chips is not profit, but an indirect loss, as it takes away from the price of their quilled cinnamon.—Truly yours,

A YOUNG PLANTER.

THE CULTIVATION OF TEA IN THE GALLE DISTRICT.—The cultivation of tea is not only rapidly on the increase in the district, thousands of pounds being now regularly forwarded every two months once to Colombo for public sale at the Chamber of Commerce Sales' Room, but it will be seen that its manufacture is well understood by the local producers, and compares very favorably with the tea placed on the market from other parts of the island, where the conditions of soil and climate are generally considered more favourable to its growth. At the sale of the lots put up last Wednesday, by Messrs. Forbes & Walker, it is well to mention that one tea garden alone in Galle, situated barely four miles from the town, contributed 2,332 lb., and the exceptional quality of the manufacture may be gathered from the fact that it prominently tops the market with 72 cents realized for its Broken Pekoe, a figure not reached by any single other estate—some twenty four or thereabouts in number—the teas of which had been exposed for sale by the same firm on the day in question. To prevent misapprehension, it is right to mention that, taking the bulk of the teas (sold last week by all the five firms of brokers), bearing the distinguishing marks of some 65 estates in all, the price realized for the same was 65 cents, 10 lb. down for 294 crates, mark "M. C. S." is the only one instance in which the sum of 72 cents for Broken Pekoe has been exceeded, the value, as given in the list published in your issue of the 11th inst., being 65 cents, which, if not a misprint, is presumed to represent the price realized for Orange Pekoe, must be a figure paid for a splendid tea of the description given far above the general run of teas.—Galle Chronicle, November 14th, 1888.—Local Examiner.

AN OLD CEYLON PLANTER IN BRITISH NORTH BORNEO.

Mr. P. Christian, for many years a planter in Ceylon during the old coffee days, sends the following letter to a friend here, who has kindly placed it at our disposal. Writing under date Oct. 3rd, he says:—

"Your letter received, but I still think you should stick to Ceylon, unless you can go somewhere else with £1,000 in your pocket, or to a certain situation with a good salary. Land here costs \$1 per acre, but planting operations must be commenced within 12 months after selection, or it is forfeited. This is to prevent speculators obstructing progress, and the same rule is carried out in India, Burma and Australia.

"I am the only English planter here; all the rest are Dutch and German, from Sumatra. They plant tobacco, which is a most profitable cultivation, but only people with very large capital can go in for it. The Government do not need any more people as far as I know; in fact I think they might do the work with the half of them. You just wait a bit and see how things turn out. But you might study Malay. It is very easy to learn. Get Marsden's grammar and dictionary. Malay is the language in the Malay Peninsula, including Singapore and Penang, also in Sumatra, Java, Borneo, Celebes, &c., and is of course a useful language to know. If I had travelled all through the planting world 15 years ago when I could have done it, I would never have been ruined. That nonsensical idea of 'Coffee is King' did for us. It gave the trees leaf disease and us hemileia on the brain. Many thanks for the paper you sent; Ceylon seems in a worse plight than I thought it was. I fancied that tea was selling well and people making money. I was sorry to learn from your letter than I— and W— were dead. I never heard of it. I never get a letter, but someone dies that I would like to see again.

"So B—and I—are in America. Well I hope they will get easy times some day, that is, if they are as tired of hard lines as I am. Burma is a good place to go to, with a few hundred pounds. In Tavoy they give up to 1,200 acres of land for nothing till 1895, and then 7 annas an acre, but one could pay by that time. There is a fine field there too for surveyors. A railway is certain to be made into Yunnan in China, either by Bamo or Moulmein, or both, and perhaps from Assam. Read up Burma, and China bordering on it and Siam. I will have ripe Liberian in a month or two from 20 acres, but I can't afford a pulper or pulping-house, but I dare say I shall manage somehow or other. I lost 4 or 5 acres newly planted land at the beginning of the year by deer. They bite the plants in two, and the supplies they pull out. I never was troubled with that in Ceylon, and we had the same deer there—the sambur or elk as we called it. There were cheetas in Ceylon to keep them in order, however, and we have none here, so deer, pigs and wild cattle are too plentiful for farmers."

TOBACCO is accepted by Rev. W. J. Woods, B. A., of Clapton, as "a gift from heaven," and those religionists who condemn its moderate use are regarded as "successors in office of the Pharisees". Mr. But Woods, who contributes a paper on smoking to *The Young Man*, pertinently adds, "I hold it my duty as a smoker to maintain perfect mastery over the habit; to discourage the practice in all whose physical stature is immature: to forbear from obtruding tobacco upon those who dislike it; to consult my wife's wishes respecting the rooms in which I smoke at home; and never to light pipe or cigar in any other house except by invitation of my host. In a word, I hope I take my pleasure as becomes a Christian gentleman."
—*Christian World*, Oct. 25th.

TEA FROM THE SOUTH SEA ISLANDS.—The *Grocers' Chronicle* in a late issue writes:—Those who have watched how in India, Java, and Ceylon, the experiments in tea planting have, after much patient effort, proved commercially successful, will be somewhat prepared to note that in the South Sea Islands similar experiments are being made. Messrs. Pringle and Crichton, tea merchants, of Glasgow, have called our attention to the fact that they have just added to their wonderfully interesting and instructive exhibit of the teas known to commerce in the Glasgow Exhibition, two samples of tea—Pekoe and Pekoe Sou-chong—grown in Fiji. Although we have not had an opportunity of examining the samples of this, the latest attempt to extend the growth of tea, yet we are quite prepared to take the word of this well known firm that "they are very well made, fair liquor, with trace of Java flavour, and considering the newness of the undertaking, very promising," and we congratulate this firm on the enterprise they have shown in thus demonstrating to the public what is being done in the way of developing the production of tea. Although we believe so far the attempt to grow the plant in South Africa has not been followed by any very marked success, yet the samples we have seen would indicate that with increased experience something might be done there. But this new departure in the South Sea Islands has apparently been patronized by the New Zealand buyers, who are reported to have taken two hundred boxes, and if in this early stage this leaf has thus commanded the market, we see no reason why we should not ere long hear of some being offered in Mincing-lane. Certain it is, as we pointed out last week, that the supremacy of Chinese growths in English markets is now gone beyond probability of recovery, and it must be highly satisfactory to the people of Great Britain that her tea supplies are coming forward in steadily increasing quantities from various parts of Greater Britain.—*Indian Tea Gazette*.

PROGRESS IN UPPER BURMA.—From the Commissioner's Administration Report for 1887-8, we quote the following satisfactory summary:—

The results of the administration of the past eighteen months may now be briefly summarized. The police force has been organized and brought up to strength, and the work of maintaining order, which a year ago was performed by troops, is now being efficiently done by the police under the immediate control of Civil officers. In the case of serious disturbances the aid of the troops is sought and is always cordially afforded. Except in two or three districts there are now no large bands of dacoits, and there are not more than four or five dacoit or rebel leaders of any note or influence in the province. Jails have been or are being provided. Court-houses have been built. The Medical department has been entirely re-constituted. Enquiry has been instituted into the revenue system of the country and preparation made for its establishment on a firm basis. Municipal institutions have been introduced. The village system, the basis of the successful administration of the country, has been organized in accordance with the customs of the people, and the hands of District Officers has been strengthened to enable them to administer their charges with the aid of the well-disposed portion of the community. The result has been satisfactory. In every district the people are daily becoming more accustomed to our rule, more willing to aid in the maintenance of order, and more ready to recognize that their interests and those of the Government are identical. During the period of report the Chief Commissioner has visited each district of Upper Burma and has met the leading men, taking advantage of every opportunity to point out to them their duties, privileges, and responsibilities, and to establish confidence in the stability and justice of our rule. There is every reason to believe that a course of steady and continuous progress in all branches of the administration will be sustained throughout the province.

AGRICULTURE IN MALACCA.

MALAY IDOLENCE.—The Malay, who is of an improvident disposition, and entertains peculiar aversion to hard work, will never, we fear, be induced to emulate the thrift of the Chinaman. Only the other day a Malay cultivator of padi was spoken to on the subject of agriculture, and he was asked why he did not engage more extensively in padi cultivation. "Well, you see," he said "I have four *koyans* of padi a year, two of these I keep for my family, and the other two I sell. A *koyan* brings \$15, so that I get \$30 for my two *koyans*. This means \$750 a month, a sum which keeps myself and family in comfort until the next harvest." This gives one a fair idea of the disposition of the Malay. It is on this account we assert that Government should use all its best endeavours to induce the industrious Chinese to take to padi cultivation, if it is desired to grow sufficient grain for home use and for exportation.

PADDY GROWING.—While we deplore the smallness of the area under cultivation, and the very meagre crop produced in the cultivated portions of the Settlements, the present occasion may not be unfit for briefly pointing out why this branch of agriculture is not more generally successful.

We frequently hear it remarked: "Why does not the Malay grow two crops of padi in the year?" The answer to which is, because the Malay grows a crop of padi during one part of the year, and during the other part he grows what has been styled a crop of manure. But he has a special difficulty to contend against in many places, and that is the want of water. If padi planting is to be made a successful and remunerative undertaking, and all available land put under cultivation, a proper system of irrigation must form the first consideration. The padi lands of Malacca offer no special difficulties for this work. Canals could be dug which would ensure a copious supply of water in dry seasons, and drain off superfluous water in exceptionally wet ones. Few plants, however aquatic in their requirements, will thrive when immersed "head over ears," we may say for any lengthened period in water. In wet seasons a large area of padi is destroyed by inundation, and, so long as this state of things lasts, we cannot wonder that, independent of the cultivator's idleness, the supply of padi is limited. The irrigation works should be taken up by Government with as little delay as possible, for a proper irrigation system would, as we have said, secure the crops against heavy rains or drought, and inspire the half-hearted planter to go to work with greater cheerfulness and confidence.

CAUSES OF FAILURE.—There are very few of the inhabitants of this place who understand anything of planting, and many thousands of dollars have been wasted in trying to grow crops of various kinds on ground which has been totally unsuitable, a result which an expert would have foreseen with a glance at the soil. Tapioca will grow everywhere, and it requires little attention; but the objection to it is that it impoverishes the soil. We cannot expect tapioca to be superseded by more desirable plants until planters acquire some knowledge of their habits, the treatment they require, and the most suitable soil to place them in. This is a difficult task, and one that would demand much toil and patience. But we think the Hon'ble the Resident Councillor has hit upon the right plan, and the most desirable results may be expected from the holding of an Agricultural Exhibition, for which a vote of \$500 has been taken. In the meantime we have a great fancy for the idea of having a few simple instructions and some general information printed in Chinese and Malay, and the Natives might be induced to visit the Experimental Gardens where copies of the instructions, &c., could be procured, and where the plants could be seen growing.—*Malacca Weekly Chronicle*, 20th October.

BANANA CULTURE IN NICARAGUA.

Under the title of *Banana Cultivation on the Rama River, in the Mosquito Reserve, Republic of Nicaragua*, a Consular Report specially devoted to this subject has recently been issued from the Foreign Office, of which the following is the substance:—

This trade, it seems, has entirely sprung up during the last few years, the first shipment of Bananas for exportation having been made in 1883. The river Rama flows from the junction of two small streams, the rivers Escondido and Sequia, to the Bluefields Lagoon, on the Atlantic coast, a distance of some ninety miles, and previous to the year 1883 the banks of these rivers were uncultivated and uninhabited. About that time the Mosquito Fruit Company cleared a tract of land, with a frontage of three miles, on the river Rama, and commenced the cultivation of Bananas. The first shipment, consisting of about 500 bunches, was made in the latter part of 1883, the fruit being sold at the vessel's side at the rate of 50 cents (Nicaraguan currency) per bunch. The success that attended this first attempt induced many persons, including several foreigners, to commence the cultivation of Bananas, and now the whole of both banks of the Rama River, commencing from about 20 miles from the Bluefields Lagoon up to the junction of the rivers Escondido and Sequia, and such parts of the last-named rivers as are navigable for canoes have been cleared and cultivated. The banks of the Rama River, for about twenty miles from Bluefields, are not adapted for cultivation, being too low and swampy. The following figures will show the rapid growth of the exportation of Bananas from this country:—In 1883 the number of bunches exported was 8000; in 1884, 40,000; in 1885, 45,147; in 1886, 154,434; and in 1887, 255,332.

To ship the Bananas during the year 1887 there were six steamships, each making monthly trips to the United States, where the whole of the fruit is sold; two of these steamers carrying their cargo to New Orleans, three to Baltimore and Philadelphia alternately, and one to New York. These steamers have not only to be fast, to enable them to arrive at their destination before the fruit ripens—as it has to be cut whilst still green, and handled with the greatest care, the slightest bruise leaving a black mark, and consequently depreciating the value of the fruit—but the steamers have also to be of light draught, to enable them to pass the bar of Bluefields Harbour which has only some 14 feet of water. Once inside the bar, the steamers proceed up the Rama River, which has a considerable depth of water—in some places as much as 50 feet—and, calling at the various plantations on the river banks, purchase the Bananas that may be ready. In consequence of the greater part of the planters refusing to accept the low prices offered by the steamers, many of the vessels have been withdrawn, leaving, at the present time, it is stated, only two steamers making monthly trips—both to New Orleans—and in consequence a large quantity of fruit has ripened in the hands of the planters, and has rotted for want of means of transportation.

A plantation of 10,000 Bananas would cost, including clearing the ground and planting, about 10,000 dols. currency. It would commence to give fruit in nine or twelve months after planting, and would last about five years; after that time the ground becomes exhausted, and the fruit so poor as to be unmarketable. The Bananas grown on the Rama River are the ordinary yellow Bananas, about 6 to 8 inches long, and a red variety known as the "Patriota." This is smaller than the yellow form, but has a sweeter and finer flavour.

When the Bananas are stowed away in the steamers they have to be kept shaded from the sun, and the temperature whilst in the tropics must be kept as low as possible by means of a free circulation of air; but in spite of all precautions, some bunches always ripen and are lost during transit, and in some few cases owing to the steamer having been obliged to batten down her hatches from heavy weather, or other causes, the whole of the cargo has been lost. According to the rules of the trade, eight clusters, or hands (as they are technically called) to a bunch forms a whole bunch; bunches having from five, and under eight clusters, or hands, are counted as half-bunches; and, as a rule, the steamers refuse to take at any price bunches having less than five clusters. J. R. JACKSON.—*Gardener's Chronicle*.

LOWCOUNTRY NATIVE PRODUCTS:
COCONUTS AND COTTON.

DROUGHT—TRANSPLANTING—ADVANTAGES OF A DROUGHT
—COCONUT CULTIVATION—CRITICS AND CRITICISMS—
COTTON.

(From a Native Correspondent.)

7th November 1888.

The drought which lasted for nearly 3½ months this year did its full share of damage on coconut and paddy crops, many a poor goyia lost his entire crops owing to it, and they will be in a sad plight for the seed-paddy which they require for the next season's cultivation. So they will have to resort to the seed-paddy lenders who take 100% on their capital, which is a hard drain on the poor cultivator. This practice prevails to a great extent in the rural villages, and it will be for their good to bring some measures to check it. There is one thing which, if generally adopted, will free the cultivators of the necessity of borrowing. It is the system of transplanting. It requires only eight seers of paddy per acre, while the method of broadcast sowing requires ten times the amount or two and a half bushels of paddy. It has also been already demonstrated beyond doubt that the transplanting system yields very much better than broadcast sowing. Any experienced goyia would admit this. Now what is the drawback for their not adopting this, and what will they say if questioned; they would always say it requires more labour; and it is perfectly true. But without considering the ultimate benefits, if we were only to take to account the saving of seed-paddy, it will at once be proved otherwise. If the labour for transplanting be paid for and hired labourers engaged, an acre of paddy land could be planted easily by 2 men and 12 women which costs in money only two rupees. But the seed-paddy saved through this method will be worth at the rate of one rupee per bushel, two rupees and 25 cents. The above will show that it is not at all a bit more inconvenient to transplanting than to sow broadcast, and the system if brought before the goyias should but eventually be accepted by them. This is worth while being considered, especially where seed-paddy is lent by Government to distressed goyias. They should only be given the amount necessary for transplanting, and if they themselves are unable to transplant their paddy, it could be very well done by spending a part of the savings which will amount to R2-25 per acre. Not only will the cultivators get better crops from their lands, but even the most conservative of them will learn to adopt the system which they themselves would see to be greatly beneficial. And the Government which lends the required capital will, instead of spending the whole, have a small saving, and also at the same time will force upon the cultivators a system which will increase their yields without any inconvenience either to the Government or the cultivators.

It is worth while considering whether a drought is an unmixed evil. I for my part will not think so. It is true it plays great havoc on our crops, but at the same time it brings with its train some advantages to the cultivator also. On account of a drought the sun-heat in its course of evaporating the moisture from the soil, draws it from great depths. The more the drought is severe the deeper does the action go in the soil. And the water in its course upwards to the surface brings with it a deal of fertilizing matter from the undersoil, where there is no probability of the roots ever reaching them. Such matter when brought to the surface in solution with water is left on the upper soil, where the water is evaporated, and this gain is sometimes remarkable where they have rich subsoils. By the above process many an unfertile soil is made to produce good crops. And it is not unfrequent to have good crops the season following the one of abnormally dry weather. Thus we see one of the benefits on account of a drought. It also makes a cultivator to leave his land in fallow though unwillingly and unintentionally. This may be taken as one of the reasons why most of our Ceylon paddy lands do not get exhausted, by almost continuous cultivation of

one crop, sometimes without any sort of manuring. The land is laid under fallow, and a good deal of fertilizing matter is added to it through occasional droughts in the course of three or four years, and it becomes a blessing in disguise. Ceylon cultivators have never understood or have recourse* to any fallowing or rotation to restore the fertility of their soils. But in other countries even in ancient times they had a method of leaving land in fallow. For instance, it is said that in Egypt they were required to fallow all their lands once in seven years, and among old Saxon cultivators they had what they called an 'arable mark' and left one-third of their lands always in fallow. But here we have no such fallow or arable mark, and occasional droughts which occur at intervals and which force the cultivators to leave their lands without crops serve as a system of fallow.

In regard to the cultivation of coconuts there were some theories expounded in a Sinhalese paper a few weeks ago. I shall mention some of them here rather for the amusement of your readers. The writer says that it is very destructive for the trees to plough or dig any coconut land or either to trench round trees for manuring. With respect to this he criticises the pamphlet published lately on the subject in Sinhalese, and says that in such and such pages of the pamphlet the author gives the most destructive process for coconut lands, and which is followed foolishly by many intelligent cultivators to the destruction of their valuable trees, and he goes on advising the planters to get their lands scraped or hoed without disturbing the soil, and then heap the rubbish round the trees, and he goes so far as to give a diagram for the instruction of his readers. What will your well-informed and practical correspondents on the subject think of the above? The only thing for regret is that the giving of prominence for such letters in the papers without at least referring them to some one who could form an opinion about them.

While speaking about critics and criticisms let me give you some of my experiences about them. For instance, in connection with the pamphlet on coconut cultivation lately published, some parties went so far as to condemn it entirely only taking into account parts of sentences, and would say that some of the information were sound in theory but not in practice, &c. And there was another thing which such critics had resort to, that of mistranslating parts of it representing them to be parts of the original, thereby trying to deceive those who could not have read the book for themselves. Criticisms well expressed are always for the mutual good of both the parties, but the intention of such ones as I mentioned before are obvious.

I would mention a word about the new product for the lowcountry of Ceylon which is attracting attention at present, I mean cotton. Experiments are initiated in different parts of the Island; and they, I am sure, will yield us valuable information. But those experimentalists should be careful to give the kind of seed they used, as some kinds of seed are not at all fit for our climate or soils. For instance, the Tinnevely seed. In Tinnevely cotton is grown in black peaty soils,† and the soils are also very deep. So the plant use to send its roots far into the soil and get its nutrition. Another point is, it does not prefer excessive moisture or excessive heat. Both these are not present in that district. Because there is no scope for excessive moisture as the rainfall of that district is comparatively very little, and also as the peaty soils have a remarkable property of absorbing moisture, &c., from the atmosphere the crops do not suffer from excessive heat. Such climate we cannot expect in most districts of Ceylon, as during monsoon weather we

*This is surely too sweeping. Between Colombo and the hills, large tracts of paddy land may be seen for years devoted to pasturage, which when rested and enriched with the droppings of cattle, &c., are at intervals cultivated.—Ed.

† We never before heard the black cotton soils of India described as peaty.—Ed.

get plenty of rain and excess of moisture followed by as dry weather afterwards. So it would not be a matter for surprise to hear of the failure of cotton in most places where this kind of seed were used. The Egyptian, Brazilian and Pijian cotton would, I think, thrive better in our districts, as they can very well stand the extremes of weather. I have found the Egyptian cotton to stand three weeks of dry weather just after planting and as much rain after that without any apparent injury, whilst all the Tinnevely planted along with them suffered a sad end.

W. A. D. S.

OUR MANCHURIAN SILKWORMS:

THE OAK-SILK INDUSTRY: NO. I.

The curse of China, as I have seen it, is the want of fuel. Unless, indeed, one go a step further back and say, the true blight is in the apathy of the people, who are informed that they have more fuel stored underground than any country in the world, and yet make no proper effort to use it. And then logic compels us to go further and say, the poor people are ground between two curses: superstition, which makes more of lucky influences than of mineral wealth; and certain unfortunate defects of government, whereby magistrates are compelled to make merchandise of their offices, and are especially tempted to enrich themselves at the expense of new industries. It used to be heart-breaking to me to see the utter desolation wrought on the hills in Shantung. Nothing was safe from the fuel gatherer: everything breakable was broken; everything scrapeable was scraped; what could not be dug out was backed; and a general spirit of destructive recklessness seemed to animate young and old alike, the hereditary transmission of long years of over-population. It seemed a relief to come to Manchuria, and to find one's self almost always within touch, always within easy travel, of luxurious vegetation and wood-clad hills. But alas! every ten years tells us what strides we are making towards the guilty poverty of Shantung. We are not making much of our mineral wealth, and we are smashing up our timber. Thirty years ago, the east of the province was one unbroken belt of forest. The timber stood everywhere in the settler's way. Some little of it he got floated down the Yalu, or dragged to the cities. But it was a drug, and many a fine beam have I seen rotting in the creek where it fell. Then came the doom of the oak scrub. And the Chinese been Anglo-Saxons a few enterprising men would have made fortunes out of the silk industry. They would have done with silk what our countrymen have done with wool in Australia. The conditions are most favourable: a first class oak-growing country; a superior climate; maple on lots for commerce. What an opportunity! The land becomes the inalienable property of the settler. The hills and streams are his, the woods and forests, the feathered and the furred tribes; and he has to over-look, none nearer than the distant Emperor, who claims the paltriest of taxes in name of allegiance. Yet all this glorious opportunity has been thrown away. Emigrants have come in like ants. The very oak scrub begins to be eaten up. It is fast disappearing where it was once the feature of the landscape. In my own time I have seen the oak-belt receding from the seaport from year to year. It is so far removed now that even with winter roads it barely pays to bring it in. Then instead of the silk merchant, the distiller has laid his hands on it. He plants himself in remote valleys by clear pebbly stream, and converts the oak-scrub into fire-water for the million. Fuel is the cry, and the chances of the province becoming the seat of a great silk industry are lessening yearly. What is to be done? The people must live. And so the fuel cutter and the silk grower get to bicker heads. One village guild decides to use its lake-side oak for silk; its neighbour village values it only for fuel. These are the Chinese lawyers of the oak, and I have agreed hitherto to refrain on each other's rights in the use of the oak-patch. But fuel cutters trample on the silk industry. Strike aches, a law-plea, a feud; and the men of the one village gather silently

at midnight, and burn their enemies in their houses. Thirteen charred bodies were there to tell the ghastly tale, while so bitter was the feud that the district Magistrate dared not approach the scene to hold the customary *post-mortem*. But this incident shows also that the people are alive to the value of the silk industry. What we suffer from is the want of connected action. Silk growing is carried on everywhere. In some districts it takes the place of a staple industry. We have southerners resident amongst us who, some of them, would seem to represent capital. I hear wherever I travel of a foreigner who buys largely and gives wise suggestions, which have already led to an increase in the value of the silk. And yet the trade languishes—certainly does not play the part it ought. There are now fewer silk houses in Hai-ch'eng than there were five years ago. I have talked with members of many families who say they have been impoverished by the trade. The people's means are too limited. I frequently hear of a venture of Tls. 10. I knew such a man last year who lost his entire crop in the wet season. I hear of Tls. 50 ventures, of partnerships in which larger sums are distributed among ten or twelve people; but never of any such capital as could possibly create an industry. I fear the common run of things is for a man who has a few taels to say to a man who has rights on the hill: "Let's club together—you give the hill and I find the worms and do the watching, and we shall halve the proceeds." Or a silk merchant goes round and advances small sums—usually without security—and trusts to the honour of a number of poor families to recoup him in a good season. This is all very well in agriculture, where there is commonly security in the land. But the humble silk grower rarely owns his oak-patch. He rents it for a trifle from a temple, or from a village guild, or from a peasant farmer who has had the luck in his original settlement to be first on the hill and to claim it as his own. Foreign merchants therefore are helpless. In their case nothing can be done without capital. For they want a better cocoon better reeled. To this there must be improved knowledge of silkworms improved machinery, and concentrated effort. Who is to head the movement? Who is to stimulate and foster it? The foreigner cannot, were it only that he has no security for his money. In these circumstances it is gratifying to see a most promising move made by the Chinese Maritime Customs. It is foreign to be sure in its inception. But from the character of the men with whom it has originated, it is bound to work itself into the Chinese mind, and to carry with it the sympathies of the highest officials. For this purpose questions have been drawn up in Chinese eliciting scientific information as to the varieties of silk-worms to be found in the Eighteen Provinces. Domestic, semi domestic, and wild—nothing which can by any means claim affinity with the silkworm is to be omitted in these researches. These queries are to be distributed in book form all over the silk-growing districts. They are so prepared that there is room beside the query for the answer of any silk-grower who may be large enough minded to give replies. It fell to me to distribute these in our province; and I must confess there was the usual difficulty. It emanated from foreigners, and of course excited the inevitable low-born suspicion of foreigners. And again it emanated from the Customs, and there were actually fools enough who scorned to help in it as deeming it an artful dodge of the government to put some new tax upon their industry. So the work fell to the missionary and his Christian converts. I would recommend with all deference that the Customs now apply deliberately to the missionaries for help in this matter. As an order they are more deeply than any associated with the history of silk. They introduced the original silkworm to Europe. They have ever and anon been the discoverers of new varieties. They are not new as in old days located in seaports, but are distributed over the interior; and there is not a province in China where they are not represented. It would only be to the honor of missionaries to help in such a work—to return China's original gift to us with interest by giving her

the benefit of our scientific knowledge and improved skill in what was once her exclusive domain. I have no means of knowing the general result of the above enquiries. But for this province (Manchuria) the results have been most gratifying, and promise to be of immediate benefit to commerce. In my own collection, not to speak of new varieties of wild silkworms, there were two new varieties of the oak-feeding worm commonly known as *Antheræa Pernyi*, one of which has now been named *Antheræa Hartii*, in honour of one whose name is supreme as a benefactor of China. The hunt being above all things for new species, I had live cocoons collected over a considerable area, and where practicable had the worms brought to me when about to spin. I had not a hundred cocoons in all, and none of my specimens represented the far east nor the north-east of the province, to which resort is often had for fresh seed when disease invades us. Yet from this small collection it was made manifest that the Chinese are ignorantly cultivating three varieties higgledy-piggledy, in utter ignorance on the part of many that these differ widely in the quality of the cocoons. When the black-brown moth, now named *Antheræa Hartii*, startled me by its novel appearance, I sent for a grower, who answered my query, "Is this not an unusual colour?" by the careless reply, that several of these were sure to appear annually in his son's oak-patch, but that they make nothing of them. To test the statement I sent him to bring me some, and in three days he returned, not indeed with the five pairs demanded by the Customs, but yet with five males and two females. He was a little late, he said, or he might possibly have picked up more, but no one there had noticed particularly the difference among the moths. This was in a small Tls. 10 venture. When I got what seemed a new variety I used to pin it on the wall, and bring in my friend for his opinion. He had seen them all before, and always in the same stock. And in spite of certain peculiarities of the Chinese mind well known to us long residents, I am satisfied the man was right. In making further enquiries this year in regard to the other new variety, a very fine yellow moth, I have, however, found a farm where some twenty thousand worms are kept strictly apart, worms of a bright burnished yellow colour, altogether distinct from the ordinary green worm, and these are thus kept by themselves because the grower is aware they produce a much finer silk. I was unfortunate enough to lose the moth season this year—the season of eclorion—in consequence of the unusual rains. But there is no doubt these are the worms of the yellow moth. There is every reason, then, to believe that the province is rich in varieties, and that the Chinese, true to themselves are jogging among in ignorant courses. Even when an individual hits on knowledge, he keeps it to himself, lest by communicating it he should enrich others. All honour to the customs, therefore, for this move. It is to be hoped we are only at the beginning of a great movement by which foreigners will repay China for the long centuries of benefit we have received at her hands.

Worms are not generally supposed to be an interesting topic, yet in a silk district it is not an offence to speak of them even at meals. And really one begins to lose one's natural horror of the caterpillar tribe when one has had even a slight acquaintance with the gentle family of silkworms. I was once initiated by an old enthusiast into the mysteries of bee keeping, and advanced far enough to know how it takes the form of a craze in many, when one's bees know one, and can be handled summer or winter and recognize the fingers at the feeding slide, even when one does give it an unfortunate jerk on a cold day and brings the nimble sentry upon one's finger nails:—well, worms are not bees. They are like friends with fishy fingers, which make one cold at the touch. It takes some time really to get into the state of craze. Yet, after all, it is imagination. I remember in one of my visits to the Far East my attention was arrested by a party of very swell young Chinamen, who were loitering about with great fat green

caterpillars crawling on their silk sleeves. They seemed to despise me that I did not show appreciation of their fancy. I saw only great, fat, ugly slugs, which I had not the courage to touch, and which if put on my sleeve would have made me creep. Now I wish to describe this slug—for it was none other than the oak-silkworm when about to spin; and to give an account of some three or more varieties I have met with, in the hope readers will be willing to make its acquaintance, and in fact (where they have opportunity) to push its fortunes in the world. One would not think there was much romance in the life of a worm. But look at this worm's enemies. When it is but a tiny little black mite, and indeed to the close of its second stage, it is a tit-bit for the ubiquitous sparrow. It then passes into the hand of the magpie and the crow—the former more especially being a cruel Pharaoh, and quite equal to the extermination of a stock. When the worm is just ready to spin, has no further excrement, and is pack-full of the essence of silk, a pair of four-footed persecutors appear—shall I be believed when I say it?—the fox and the badger. But where is scepticism when I say the Chinese themselves feed on them at this stage, and deem them a delicacy. Here are foes enough. But we are not nearly finished. The big formidable wasps of these parts prick them and suck the juice. So does another enemy which I cannot name in English—the Pi Pa Tsan—and which is even more dreaded than the wasp. The elephant ant worries them always, even to the spinning stage. I have seen an ant attack the head of a four-inch sleeping beauty when resting after a feed—resting with body in mid-air and help only by the tail and feet-prehensiles. The spider is also an abiding plague, blocking the way of the worms as they move from twig to twig—and of course making a meal of the younger ones. And as the spider traps them on the tree, so froggie gapes for them when they fall on the ground. Once on the ground, alas! their enemies are legion, and escape is rare. Is it a mere Chinaman's legend that our children's friend, the fairy little "lady-bird," is also an enemy? It is said to be blown from the land rocks in locust-like clouds, and to settle upon the oak scrub to the injury of the silkworms. But would naturalists believe it sucks their juice? Even on poetic grounds one would fain hold it a libel. Yet the culprit brought me seemed indisputably a "lady-bird." There are also enemies which interfere with the food of the poor creature. The chief of these is a caterpillar, supposed to belong to the *Lesio-campidæ* family, which I have seen destroy an entire oak plantation—a whole valley so that not a leaf was left. Even where present in moderation this is a trying plague, as the silkworm won't touch a leaf which its enemy has tasted. Then comes a round of fell diseases which seizes the worm in its later stages, and which often in the very last stage robs the grower of his hope. One is the yellow disorder in which the worm assumes a sickly yellow colour. Another is the yellow spots, which show in yellow spots like blisters. A third is the black rust, showing in minute black spots like pin points, sometimes dotted over the whole body, sometimes more sparsely along the sides. A fourth is the black spots or bars, showing in larger spots than in the above and in streaks. The last may be described as diarrhoea, known by the excrement clinging to the worm and not falling free. Worms in the power of any of these diseases are considered doomed, and in some seasons a whole stock will suffer. It is hard to say which is more dreaded where nothing is to be hoped from any. But perhaps the black rust is more common in our parts, and as it is a plague of water or damp is most dreaded in autumn, after the summer rains. But when all these are passed, there remains in our latitudes the plague of the north wind, an exasperating one in this, that it frequently arrests the healthy worms within a day or two of spinning, and leaves them as it were spiked on the tree in a comatose condition, when time is precious and a few days loss means simple doom. As early as the 27th September this year I saw whole bushes,

the worms of which though perfectly healthy were pronounced late and unfit to spin—even with a change of wind; and when they do spin, the cocoon is, of course, thin and valueless. So much for the romance of danger. The varied life of the worm has a touch of romance in it. It does not pass its days in a musty Chinese house, but in the open. It is not set out in artificial plantations close by the villages, as in Shantung, but, like our bees in summer time, it is taken to the hills. The moth is tied to a twig to lay its eggs on the leaves, or, when the eggs are hatched in the house, the infant worms are brushed off from a tray, and soon settle to work. The bush itself is not imposing—in our parts. It is kept well cropped, as much for the sake of fuel as to promote the growth of fresh leaves. It is so low that Renard might scan it all over without rising on tiptoe when in search of the sweet essence of silk. It is so small that a company of full grown worms will eat it up in a day, and have therefore to be constantly removed from one bush to another. We have to go very far east to see respectable shrubby trees where the worms can manage fairly well for themselves. But where I have seen the worms, it has been in the midst of charming scenery. In spring and autumn they have the company of some of the loveliest birds of passage, some of which are sweet birds of song. The hill sides are beautified at times with a perfect wealth of wild flowers. There is occasionally the clear, rustling brook with its moss-grown rocks, and the secret treasure of ferns. And nestled in these sweet nooks, they have even there their changes according to the seasons. They pasture upon the airy heights in summer, and they are early withdrawn to the depth of the valley to avoid the autumn winds. In such scenes, then, the worms go through their various stages. First a little black mite, then a green worm, interesting from the variety of the shades of green through which it passes, and developing into a ring of formidable proportions, the bulkiest of all our silkworms. Nor is the worm altogether unworthy of its surroundings. The green worm itself—I speak of the full grown worm—is beautifully marked, though few would say so at first sight. Conspicuous is a brilliant yellow line along the sides at the base. Just under this, along the length of the worm, are nine remarkable oval spots on each side, composed of a gold line enclosed by two black or black brown curves. These spots begin on the first ring, miss the second and third rings, and then go on unbroken to the tail. In every case I have seen, and I have examined many hundreds, the mark on the first ring is lighter, the gold line being set on a light brown ground. Immediately under this again there is a line of hairy tufts with bright blue base. When perfect there are eleven on each side, beginning from the first ring. Some worms, indeed many, have only a few and in some again they are altogether wanting. There are other three such tufts with a blue base on a lower line on each side, one right over each claw. Less conspicuous, because colourless, are two lines of hairy tufts along the ridge of the back, two on each ring. But where there are "gold stars" on the worm a certain proportion are always found forming the base of these tufts, and then the effect is very striking. The blue base of the tufts above spoken of is small, a mere pin point, and does not readily catch the eye—many Chinese who handle the worms are unaware of their existence; but the gold stars flash out in the sunlight like pearl drops. In a sense the most prominent trait in the worm is these gold stars—when they are present. But I have mentioned them last, as they are supposed to be a blemish, and where too numerous it is declared the worm cannot spin. The perfect worm should be free from them. A worm which has more than five or six begins to be in a bad way. They invariably occur on the yellow line above mentioned, and in the hairy tufts on the ridge of the back, where the number is large the majority occur on the yellow line. Where they occur on the ridge of the back there are generally two on each of two rings, with sometimes an odd one on a third ring. The fourth and fifth rings claim the greatest number, but they are not always in pairs even in those. Next

in order comes the sixth ring, while in a large number of cases carefully counted I have only found one or two on the seventh ring. The same rule also obtains in regard to the gold stars on the yellow line—the fourth and the fifth rings never escaping if there are stars on the worm. As to the number of gold stars commonly to be met with, the following table may be of use. In twenty worms taken for the sake of their various markings, two had three gold stars, two had four, three had five, three had six, four had eight, two had nine, two had ten, and two had sixteen. In another set of four, one had six, one had eight, one had ten, and one had fourteen. In another set, out of sixteen worms two had four, two had six, five had eight, one had nine, one had twelve, one had sixteen, one had seventeen, one had twenty, one had twenty-two, and only one was altogether free. But this might be misleading if I did not add that the hunt in this case was for well-marked worms. As a set off against this it would be necessary to institute a separate investigation to find out approximately how many worms are without gold stars. Certainly, in glancing over the bushes the impression grows upon one that few are altogether free. Not unfrequently these "stars" shine with the clear sparkle of silver. But, as a rule, the term "gold stars" is the appropriate one. The largest are equal in size to a large-headed pin. When the worm is in vigorous health they shine with quite a lustrous light, and the light would seem to pale somewhat with sickness, and especially, when the worms are wasting in autumn from the effects of continuous north winds. I am inclined to believe, too, that the silvery look in some is to be thus explained. The head of the worm is in itself a noticeable feature. It is large even for the worm, and has a look of the walrus about it. It has even a more peculiar look, when flattened and drawn in under the skin of the first ring during the periods of moulting. It is marked all over with bright black spots, which though minute stand out very prominently on the light brown ground. There is a method in their apparent irregularity, and I have mostly found them to consist of five large spots on either side of the head, forming on either side an irregular W read perpendicularly; and again of a few smaller ones dotted over and about the singular triangular space—slightly sunk right over the mandibles. A remarkable feature also is the hair all over the body, and above all the vigorous crop of fine dark hair on the legs extending down to the very feet, so to say, *i. e.* to the feet prehensiles. But if the green variety can make thus a good show even among green leaves, what shall we say of a yellow worm, golden yellow, with other colours marking to suit? This I have not seen noticed anywhere, and I am not aware if it has been heard of in Shantung. It makes a pretty show on a shrub, and on a hillside too, when you have some twenty thousand pastured by themselves on the same slope. These have the same head exactly as the green variety, but the colour tints show some interesting variations. Thus the yellow line becomes a rich orange colour; the blue base of the hairy tufts becomes lavender; the oval spots are all there, but appear as if a gold line were marked on a darker shade of yellow. The gold stars prevail here apparently to the same extent, and being of a reddier hue than the ground colour of the worm they lose none of their sparkling effect. The history of this lot gives us some hope for the Chinese. Some two years ago my informant observed that several cocoons which he had secured from the Jalao district as "seed," produced beautiful yellow moths such as he had never seen before. He therefore kept them by themselves. In due course it appeared the worm was yellow and not green; and their original appearance, as well as the high reputation of the East for good seed led him to devote special attention to this new variety. It finally appeared that the silk produced was uncontestedly superior to the common sort as spun by the green worm, and hence his present resolution to cultivate only this sort, which has increased on his lands to twenty-two thousand worms. It is interesting to know in this connection that a moth sent among others to Europe was at once pronounced a new species

and it would seem to be this very yellow moth in question.

There is another remarkable worm of which I was only able to secure two specimens in a patch where fifteen thousand worms of the green variety are pastured. It is in all respects like the green variety save in the head, which is coal black. One keeper made light of it. He sees them occasionally, he says, but they don't come to much—they are unprofitable spinners, and, as if in proof of his words, the very pair he gave me had no intention of spinning. But another keeper at once recognised them as the worms of the so-called black moth (the one now known as *Antheraea Hartii*) which he assured me was one of the best sorts in the province. The grower above quoted denies the connection between this black-headed worm and the black moth. But as to the black moth itself, it came also with new seed from the east of the province. At one time as many as four thousand were kept apart at one farm, and it was found to yield superior silk. But the lot was owned by a co-partnership, and was broken up and dispersed in consequence of a split in partnership. I conclude with a variety I have not seen—an odd-looking blackish hairy worm with a very red head. There is clearly a wide field for investigation. It would well repay a five months' visit on the part of a specialist, nay, an annual visit for some years to come. We can promise him interesting results, and a rare zest even to a devotee from our Manchurian climate and our charming scenery.—JOHN MACINTYRE. —*Chinese Times*.

REPORT ON COMMERCE AND SHIPPING OF THE NETHERLANDS COLONY OF GUIANA FOR THE YEAR 1887.

PARAMARIBO.—EXPORTS.—The production of cocoa, which had fallen off 70,000 kilos. in 1886, increased in 1887 by 100,000 kilos. over 1885, when the amount produced was 1,344,413 kilos.

In this year the duty was taken off the export of sugar and molasses, and the duties on the exportation of cocoa is yearly to be reduced $\frac{1}{2}$ c. per kilo. until the year 1892, when it is to be free of export duty.

AGRICULTURE.—Agriculture, as is understood by the term in England, does not exist in this colony, where no grain crops are grown, beyond a small quantity of rice, &c.: even dairy and cattle farming are unknown, and market gardening is not practised. Cocoa and sugar are the staple products of the estates in this country, and the latter is gradually dying out. Cotton was at one time procured in large quantities, but since the abolition of slavery it has altogether disappeared. Coffee, also, has ceased to be reckoned as an article of export, and all the old coffee estates have either been abandoned or turned into cocoa plantations.

Land has fallen in value in the last few years to such an extent that any investment in landed property here can only be said to be very precarious, and I would not advise any British capital being engaged in either sugar or cocoa planting. For the most part, those who have tried their fortunes here have been heavy losers. The accompanying return of land and estates sold during the past year will show how low the value of land is now in this colony, even where there are buildings on the estate sold.

REPORT ON THE CAWNPORE EXPERIMENTAL STATION FOR THE RABI SEASON, 1888.

From the introduction to this report we quote a sentence:—

The good effects of deep ploughing, green soiling, of gypsum when applied to leguminous crops and of the good value to be obtained in the shape of manure for many materials now neglected of the people, have all been demonstrated before, but constant repetition is needed to keep the memory of these facts green. There are some experiments, however, of former years that have been discontinued which may,

I think, be revived with advantage, such as growing for statistics of produce sample fields of all the main rabi crops, the cultivation of wheat on strips, with alternate strips of fallow, the pedigreering of wheat, experiments with fodder grasses, &c.

The following extracts from the Report are interesting:—

Ploughing in a green crop of hemp is a most economical way of enriching the land, and is most to be recommended for fields were farmyard manure cannot be applied with profit either owing to long distance or scarcity of manure.

Catch crop.—In a field of oats, when the plants were some four inches high, lucerne seed was drilled in which germinated well, but its plants were, of course, kept down by oats. Its addition did not affect the yield of oats, which was rather more than the produce obtained from a neighbouring field to which lucerne was not added. The crop of lucerne was kept for seed and added R12 to the profit. Where water is available this system of catch-cropping can be safely recommended in fields of barley.

Effect of gypsum on leguminous crops.—Gypsum was applied to a field of peas and gram; its effect on the former was not much, but it increased the produce of the latter by 113 lb. per acre.

Effect of certain manure on potatoes.—The following statement shows the result of this experiment: it will be seen that 10 maunds of castor cake with 3 cwts. of gypsum gave nearly as good result as 500 maunds of farmyard manure or 200 maunds of pouddrette, with 54 lb. of iron sulphate. This is, however, the first year in which the experiment has been tried, and the results require to be confirmed for future trials.

Ensilage.—A large pit was filled with *chari* and the common grasses of the rainy season. It was opened in May and proved sound; the ensilage was freely eaten by cattle.

BRITISH GUIANA.—Mr. Jenman's annual report of the Botanic Garden is an elaborate document, giving in detail accounts of the weather and the effect on the plants of a prolonged drought, albeit the annual rainfall amounted to 84.2 inches, the greater part of which fell in the early months of the year, leaving the subsequent months parched. Among the experiments recorded is that of a successful cross between *Peristeria alata* and *P. pendula*. A large portion of the report is occupied with the description of various sorts of Sugar-cane, and an analysis of their chemical composition.—*Gardener's Chronicle*.

COTTON AND TOBACCO IN CEYLON.—Anuradhapura, 28th October, 1888.—Some Egyptian cotton seed has been distributed among the land-owners to be sown as an experiment. I am sure that it is generally known that almost every village in this Province cultivates cotton and some villagers spin coarse cloth out of it! they sow cotton in their chenas together with Kurakkan or hill paddy or other fine grain. Both grow together. But not the least care is taken as to watering or pruning or manuring. The fine grain is reaped, and the cotton allowed to ripen. When ripe it is plucked and sent to the market for sale. They get only one crop and with it the tree dies. If well taken care of, I think the cotton plant will live three years on an average, and the result will be three crops at least. As it is at present, the growth of cotton cannot pay and the people do not care to grow it. But if proper instructions be given, even to the townfolk, I mean the land owners, how to sow and keep the plant, we might expect better results. The Government must teach them to grow it *systematically*, and then it will pay. Tobacco is tried only here and there. I know of two or three men whose attempts at tobacco cultivation were a failure, because it was not done in a systematic way. Only one man, who cultivated about half an acre of land, has succeeded in turning out a splendid yield. His crop is now offered R300. This is good tobacco and really worth the money.—Local "Independent."

NOTES ON PRODUCE AND FINANCE.

We hear rumours as to the formation of a Tea Trust under influential auspices. Should this Trust be formed, it ought to have some effect upon the price of Indian Tea company shares.

An effort is being made to arrange for the sale of Indian tea at the Paris Exhibition. Negotiations have been conducted with this end in view, and the idea was that in the Indian Palace which the British Indian Section will have in the Exhibition building there would be a buffet for the sale of Indian tea. Like other plans sketched out for the advancement of the tea industry, this is hanging fire for the want of funds, but efforts are being made by the Indian Tea District Association to further the scheme; and we hope it may ultimately be carried out, although the monetary difficulty stops the way just at present. The Ceylon planters have arranged their plans, and Ceylon tea will be represented at the Exhibition. No doubt, with numbers of visitors from all parts of the world, the Exhibition would be a fine opportunity of making Indian tea generally known.

The buyers at the Indian tea sales, Mincing Lane, had, on Friday last, a little discussion not altogether of a friendly nature over the question of accommodation for buyers. Mr. Fred Davis moved a resolution to the effect that non-buyers (brokers) shall not occupy front positions in the room to the exclusion of buyers. He declared that his resolution was only aimed at those brokers who occupied front seats in the room, and who rarely, if ever, bought. He said it would be within the knowledge of all present that for some months past buyers of greater or lesser position had been standing up during the whole sale, thereby causing considerable inconvenience to those near them, besides placing themselves in a very unfortunate position. The only alternative to that was that they should go to the back of the room and stand there, and they would be quite prepared to do that if there was no possibility of getting to the front without disturbing buyers. But when they saw the majority of the best seats in the room occupied by gentlemen who rarely bought any tea, they did not think that they ought to be satisfied with their position.

The resolution and the speech of Mr. Davis caused a good deal of opposition, several buyers remarking that the former was uncalled for, and that the culling of the meeting was a ridiculous thing. Ultimately the chairman, Mr. Arthur Thompson, said that to him it seemed that the resolution was very reasonable and fair. In effect it simply meant that the largest buyers should have the preference of position in the room, and both from the auctioneers' and the buyers' point of view, that could not fail to be an advantage. They suffered from too much noise during the sales; what they had most to complain of was the "buzz" caused by nearly everybody talking at once. As a rule, he noticed that the largest buyers were always the quietest. He should support the resolution, as, in his opinion, it would facilitate the business of the room, and would harm no one. They could not be proud of the way in which the business of the room was carried on; there was too much talk and too much noise, and he believed the brokers in most cases were those gentlemen who did the least business. He then put the resolution, when eighteen voted for and twenty-seven against, it being carried by a majority of nine.

The *Graphic* has something to say about Ceylon tea-growing, and it is good enough to tell us that all the mythical hallucinations about tea cultivation have exploded, and the disastrous experience of India prevented Ceylon from falling into any serious errors at the outset, which means, we presume, that it is easy enough to grow tea and make it pay if you know how. It says, "Ceylon has an advantage over India in the fact that its rains are more regular, which is a most important matter for successful tea-growing. It also possesses an advantage over Dehra Doon, Kangra, Kaimson, and other parts with facilities for getting the tea conveyed easily and cheaply to shipping ports. Railways are being spread all over the island, so that in a short time the expense of carriage

will be very small indeed: This certainly will be an important consideration, and may tend, with other things, to reduce the price of tea. Ceylon tea, while, useful for blending, and often suitable for drinking alone, is nevertheless apt to go off so much that many buy it from hand to mouth." "Ceylon tea," the *Grocer* kindly adds "seems to be at the height of its popularity just now, and although some people prophesy that it will have the same fate as coffee, let us hope that they are wrong in their anticipations, and that Ceylon will go on improving year by year the quality and supply of its teas."—*H. & C. Mail*, Nov. 2nd.

THE ERA OF TEA IN CEYLON.

A ROUND OF THE OLD PLANTING DISTRICTS :

WITH TEST CASES FOR TEA.

(By "Old Colonist.")

[Written before he received our letters on the Matale district.—Ed.]

Perhaps no colonial newspaper ever was, or ever will be, better fitted to keep alive the interest of old colonists in the scene of their former labours, than the *Ceylon Observer*. One result of this is, that it invariably leads to a thirst for more and more details. Ample as these may appear to be, particularly in the matter of tea, there are many old Ceylon men, besides myself, who feel a growing craving for more specific reports from our own particular pākum.

In every one of the various districts of Ceylon there are certain *test spots* familiar to all who have resided therein; *keys*, as it were, to the general characteristics of the locality, and it may be to 1,000's of acres beyond its limits, though clearly within the limits of the old planters' memory, so that any *reliable* hints as to the prospects of these *test spots under tea* would probably lead to important results.

Supposing, for instance, that the observant correspondent who four times a year dilates on Mariawatte's original 100 acre field were to note and report on the appearance and prospects of the conical little hill at the back of the bungalow,—many an old Gampola man would thank him.

Again, it must please many an old Hantane man to read "Peppercorn's" praise of Anthony's new clearing; but not a few who were wont to ride round the Kandy lake remembering the rather bare ridges, to the south-east, the wash from which threatened to silt up the lovely little loch, would like to know if these ridges be now really covered with verdant tea?

And what old Matale man would not give something to know how tea flourishes on Ballacada, where poor Wyllie, who had chewed coffee leaves for 30 years, at length perished for want of healthy foliage!

Or may be the anxious inquirer was a Matale East man, and thinks of the mangy heights of Midland, where in days of yore the dainty McRae hunted by day and danced hoolachan by night. Does tea grow here? * Or, say, the opposite side of the oya, on the breezy ridges of Bambaragalla, where hospitable old Bob was wont to prime the proprietor with pop, charging it to manuring, and yet the coffee went out. Does tea do better?

Over the ridge and towards the Hoolaukande gap we feel sure tea will do fairly well, though no more shall we there meet the gentle Jolly nor the real Mackay.

Once through the Gap, the overgreen valley of Kelobokka leaves little room for doubt or inquiry; but there is just one spot I would like to hear about, viz., the peatana plantation I mean the spot through which that beautiful youth Douglas

* Yes, it does, we believe.—Ed.

Robertson traced his wondrous road.* Or away farther down the valley where in bygone days Ceylon's "Vicar of Wakefield" ploughed with the Sinhalese by day and meekly watched them steal his clothes at night. Will tea prove remunerative on these patanas?

Old Knuckles bricks are not afraid of their "pakum." The sheltered valley that so oft echoed the rich basso tones of poor old Critwell will ever be green, while the hills of Lebanon so long and so carefully cultivated by A. G. K. B. must prove a valuable tea totum. Battagala and Moorage will also give good accounts of themselves, but I would be interested to hear how tea answers amongst the rocks of Gangemulle and Katooloya.

Goomera—old and new,—will do, and so will Tunisagalla, while Lovegrove in the warm valley beyond will just be "lovely," as the Yankee maiden would say. Duckwari—erstwhile the noblest and most misused of coffee watties—will doubtless now renew its verdure; but Rangala men of old will be anxious to learn how the quartz ridges on Loonagalla, which early in the sixties gave such bumper crops, now promise under tea?

From Loonagalla to Medamahanuvara seems but a hop-skip-and-jump, but it is a pretty stiff morning's walk I know. Here during the fifties reigned Eagar, the *Observer's* friend, followed by Forsyth the great financier. Round the corner is Dodangalla, for so many years a bone of contention, below which lies the wattie poor Hinck lost; but I am thinking of a wattie stretching beyond this, where that hardy son of the soil Hugh B. so long and so faithfully served his not always too appreciative '*ferrum*;' and I wonder how tea will do on Woodside? †

From this point we look down upon Dumbara, and Dumbara looks down upon tea, I am told; but if the modern salamanders could be induced to turn dear old R. B. T.'s pump upon a field of care" fully planted tea I'd much like to see the result,

Right opposite lies Hewaheta, and here there is always Hope, while the district generally has been proved suitable for the production of full-flavoured leaf; but not far round the corner there is a straggling sister upon which old Piduru pitilessly blows his coldest and fiercest blasts, and I am now more particularly concerned to hear of her prospects. I select as a test the spot where poor Middleton decided "life was not worth living and where W. W. W. was wont once a week to walk forth in all the splendour and dignity of his full-dress togs. Yes, I should like to know if tea will prove remunerative on *Mandara Nuova*. If so, my mind is easy as regards the rest of the district, and I congratulate Goodwood and Gonapatia as I move onwards, only hoping the ways of this locality have been improved. I fain would turn eastward into Walapana, though there is no room for any doubt as to this favoured spot, and I know full well that whatever is cultivated, will be cultivated to the best possible advantage by our old friend J. B., who, if not the most sanguine, is one of the very best practical planters ever imported.

I now look towards the thrice happy hills of Hapatule where the game old king dies so hard, but *die he must*, alas! and it is high time old Hapatule-hands were introduced to his successor. There is nothing to fear here: from the eastmost point, where "Ad Referendum" indited his lengthy letters, to the veritable Nonpareil

* One of the finest bits of tea in the Northern districts, or indeed, in the island of its age: "Old Colonist" had not got our letter in the *Observer* when he wrote.—Ed.

† Not yet tried: "totum" is available for "Old Colonist" to buy at "prairie" value, probably.—Ed.

in the west, there is not an acre under coffee which will not under tea take what little shine there is out of many of the mouldy districts in the C. P. There is, however an immense tract of land on the intermediate ranges, from Wellaway westwards, which it would be interesting to know what it is fit for—tea or cotton? Of opened land, take for instance the spot where poor Handyside felled the jungle by mistake and the still more terribly unfortunate de Boos struggled so long, and just say if tea thrives on "Naoola."

But I must hurry onwards: it is a long road to Rakwana, and my friends there are already looking out for me. Grand old Haldummulla on the one hand and Kalupahana on the other bring back pleasing memories of the Sixties when the shrewd P— might have been seen posturing in front of his massive mirrors long ere he dreamt of piping to the P. A. on behalf of the Great Disinterested Tea-Selling Assurance Company of N. Y.

I must not, however, go off at a tangent, and will not even stop to look at Balangoda, familiar as every acre is to me. My present object is to see *Barra flat*, the first tea planted south of Adam's Peak; and a more crucial test could not have been tried. I will not presume to inquire about returns—*it is enough, that it lives*, and I am glad to hear the produce is being specially prepared for the Yankee palate: [Barra flat with China tea 20 years old yields 400 lb. an acre, while 600 to 700 lb. are got over a wide area of hybrid.—Ed.] I have only one more question to ask at this time. Does tea thrive satisfactorily on Booloototte, the spot where giants of old buried the trunks of forest trees? If so, there is much hope for Kookoola, and I pass on to Morawaka, very familiar ground to me, and I know much better suited for tea than ever it was for coffee. There is a peculiarity in the soil of the *tongal totum* called *Goshen* where the sweater's friend developed his scientific manuring, and I'd much like to know if tea has been tried here. I must now halt, purposing a flight through Dikoya, Dimbula, Fussellawa, and Kotmale, &c., in my next.

CINCHONA.—Sir,—The analyses and yield per acre of "Cinchona Officialis" and "C. Robusta" given by "L. W. G." in your issue of the 30th Oct., would be considered low in the Kanan Devan District, North Travancore. We have no "Succirubra" or "Ledgeriana" to speak of, so I can say nothing one way or the other concerning them from actual results. Back volumes of the "Tropical Agriculturist" will give your correspondent figures to compare with his own.—A. F. M.—*Madras Mail*.

THE CUCUMBER FLEA BEETLE.—The latest thing in sensational report on insect pests (says a writer in the *Standard*) is one of what appears to be supposed by certain American journals to be a new enemy to the potato-crop. The cucumber flea beetle (*Haltica cucumeris*) a member of the genus to which our mischievous turnip flea beetle belongs, has spoiled a large acreage of potatoes in New York State this season, by puncturing the leaves till the vitality of the plants was destroyed. The notoriety of the Colorado potato beetle is supposed to have paled before that of the new pest, because while the former succumbs to Paris green as a poison, the latter is said to have resisted all attempts to kill it. All this shows, as Miss Ormerod reminds us, that our American friends do not make sufficient use of the valuable publications of their noted entomologist, Professor Riley, who, in his official report for 1884, mentioned the insect in question as known to attack the leaves of potatoes. Probably from the lack of more suitable food the pest has been driven to attack the potatoes to an exceptional extent this season, and it may be a long time before much mischief is again done by it.—*Indian Agriculturist*.

ANCIENT INDUSTRIES OF CEYLON.

(Summary of Paper read by GEORGE WALL, Esq., at the meeting of the Ceylon Branch of the Royal Asiatic Society, November 22, 1888.)

Mr. WALL began by quoting Turnour's opinion that the history of Ceylon from the landing of Wijayo in 543 B. C. was "authenticated by the concurrence of every evidence which could contribute to verify the annals of any country." History however was a record of the doings of rulers and priests, and afforded little, if any information, concerning the industries of the people. These, being the source of all national wealth, might be inferred from the facts of the narrative. After some allusions to the ancient industries of other countries, he said that their epitaph was inscribed on the monuments they had left. If the Sinhalese had been as careful as the Chinese had been to protect their territory and treasure from foreign invasion, they would have had a similar progress, instead of being despoiled by their rapacious neighbours. The ancient history of the Sinhalese, as shown by their great works, advance in art, and moral culture, proves that they would have attained a high moral and intellectual condition. But instead of protecting their defenceless coasts they attracted their enemies by lavishing gems and precious metals upon the decoration of their public buildings. The policy of the ancient Sinhalese was that of a people too intent upon their occupation, to ascend to their national interests. They were a domestic, not a political people, and continued to be such to the present time. They had therefore generally acquiesced in and acknowledged the supremacy of foreign invaders so long as these ruled them without undue rigor; when oppressed cruelly they turned upon the invaders with fury and expelled or extirpated them. The character of the people and the nature of their industries could only now be inferred from the events of history, which must have depended on their sinew, either for the things done, or for the means of doing them. Tennent had stated in his great work on Ceylon, that agriculture was unknown here in Wijayo's time and for centuries afterwards, and that the people lived on "fruit, honey and the products of the chase," but this was quite irreconcilable with the authentic facts of history. Wijayo found Yakho sovereigns, courts, social institutions, and a considerable degree of civilization, a state of things wide as the poles from that of nomadic tribes, who lived like the Red Indians of America, Bushmen of Australia, or the Veddahs of Ceylon. The sovereigns, cities, and court dresses of the Sinhalese whom Wijayo conquered, contrasted strongly with Chiefs in war paint and feathers, as did also the gems, and precious metals and luxuries of the former with the scalp, skulls and other savage trophies of the latter. The Sinhalese were called Yakhos, and they continued to familiarly call each other so to this day. It may then have been used by Buddhist historians, perhaps as the Chinese designate us British, as barbarians and foreign devils. After answering Tennent's arguments, and analyzing the events of the invasion by Wijayo, the lecturer proceeded to show that the speedy dispersion of Wijayo's small party, he to settle in Tambapanni, and they to found settlements in widely separated parts of the island, was a proof that those parts were populated, and by a peaceful people. In further proof he adduced the fact of a great embassy to Madura with costly presents to select a wife for the newly established monarch. This embassy was received by Panduwo with great favour, and he, desiring to send his own daughter as the bride, invited his nobles to send theirs to accompany her to the renowned Sina'a. The

bride and 700 noble ladies were then despatched with magnificent presents of slaves, chariots, and horses in charge of 18 officers of state, and a great retinue. Such a cortège would never have been despatched, to a country inhabited by demons, or savages, but could only, in fact, have been received amongst a peaceful people who had a settled government, and resources adequate to the maintenance of a court. The king of Madura must have been fully satisfied on these points, or he would not have sent his own daughter nor have bestowed on her such costly and luxurious dowry. These and other collateral facts proved incontestably that Ceylon possessed civilization and wealth anterior to Wijayo's landing. This was corroborated by recent philological researches, which had satisfactorily proved that the Sinhalese language was spoken long previously, and Mr. Spence Hardy had expressed his conviction that the people of that time were very far from being so rude and barbarous as they were generally regarded. The lecturer closed by adducing a number of the authentic facts of the history to prove that the country must have possessed considerable wealth to have enabled them to achieve the great works which were undoubtedly done during the reign of the conqueror, and his immediate successor. A comparison of these works with what had been done in Ceylon during nearly a century of British occupation with the advantages of several millions of imported capital, utilized by some thousands of Britain's most energetic sons, employing modern appliances, and with the aid of nearly 300,000 imported Tamil coolies in a time of undisturbed peace, could not fail to convince the most sceptical persons of the great resources of Ceylon five centuries before the Christian era.

The reading of the paper over,

The CHAIRMAN said:—I am sure I shall be only acting in accordance with the wishes of the members as well as the custom of the Society in inviting discussion on the paper and reminding those present—visitors as well as members of the Society—that they are invited to take part in it.

Mr. A. M. FERGUSON, C.M.G., thereupon rose and said:—I am placed at a great disadvantage in offering any observations on the very able paper to which we have listened by the fact that I had no knowledge of its contents until I heard it read. The practice of the Parent Society I understand is, that, when papers are passed by the Reading Committee, they are printed and very confidentially communicated to members before the meeting, so that they may come prepared to make such observations as may occur to them; and I submit that it might be well, in the case of this Society, to adopt that practice. One effect which it would have would be that the papers being in type would be printed in the proceedings of the Society within a reasonable period. At present, it is quite on the cards that a paper read in 1880 may not appear in the proceedings till 1890. (A laugh.) Having said so much, I would like first of all to remark, in fairness to Tennent, that Mr. Wall has, curiously enough, omitted a very important fact mentioned by him. The absence of the notice of any particular product in the old records is of very little value, because, as Mr. Wall has pointed out, the records being made by Buddhist priests, they confined themselves very much to what concerned the Buddhist church and monarchy. Cinnamon, strikingly enough, is not mentioned, and that has led to very great debate as to whether cinnamon is or is not indigenous to Ceylon, but, in the case of agriculture, Tennent mentions the fact that the Queen had to provide her guests with rice from a wrecked vessel. Now, if rice were culti-

vated, and in abundance, it is very strange that she should have had to resort to a wrecked vessel in order to get rice to feed her guests. As regards the race and the language of the pre-existing race, I think there is a great deal to be said for the Rev. Spence Hardy's theory. Mr. Wall has forgotten to mention one most important point on which Mr. Hardy dwells, and that is that nearly every important mountain, river and locality has a name of Sanskrit origin, and those names must have been given by a race which pre-existed the landing of Wijayo. Then comes the extraordinary problem that a Sanskrit-speaking race should be away at the Southern end of India and the difficulty also that Wijayo and his followers did not come amongst friends but amongst a foreign people whom they conquered. There is no suggestion in the narrative that they were of the same race. Quite the contrary; and there are great difficulties concerning the whole subject. I was surprised to hear Mr. Wall state that in the best poets of the Sinhalese female virtue is especially dwelt on. Mr. Wall must have read more largely than I have had the opportunity of doing. The specimens we have of Sinhalese poetry in the work of the accomplished Forbes would seem to point rather in the opposite direction. One of his chapters is headed by a verse in which the poet says that he has seen such wonders as a straight coconut tree, a white crow and an Indian fig—which, as Doctor Trimen knows, bears fruit without having had blossom on it—that they had seen that tree in blossom, but a virtuous woman I never saw. (Laughter.) That is the most prominent point in Sinhalese poetry as quoted by Forbes. As regards the wealth of the country, it may be consistent with the fact that agriculture was not carried on to any extent that they should have what represented wealth. To this day the soil of Ceylon in some parts is largely permeated by gems, and gems had a great value always on the opposite continent of India, and 2,400 years ago, or so, the soil contained immensely larger quantities of rich gems than is now the case, so that they had an immense quantity of what represented wealth in the shape of gems, and it is quite probable that the pearl fisheries may have yielded treasures also. In any case there is not sufficient proof, and I must confess that although it is quite true that the non-mention of a thing in the native records is not strong negative proof of the non-existence of the thing, yet the fact that 40 years after Wijayo's appearance in Ceylon, we have a record of the first tank that was built, combined with the fact that we know that we have no record of any tank made before Wijayo's era, would seem to show, that, whether the people grew rice or not, they certainly could not have known much of irrigation. (Hear, hear, and applause.) I think the balance of evidence is against the people whom Wijayo conquered having had large irrigation works. I have simply thrown out these few remarks, as members were expected to say something, and I can only say that having thrown out these few suggestions, I cannot sit down without expressing my deep sense of the great research, ingenuity and acuteness with which Mr. Wall has treated his important subject.

Mr. THOMAS BERWICK:—Might I be allowed to say one word in corroboration of the very cogent remarks which have just been made by Mr. Ferguson as to the inconsistency of the fact that the earliest record we have of any of our tanks, dates subsequent to the arrival of Wijayo with the idea that the agriculture of Ceylon was in the high condition that Mr. Wall would seem to imagine. Not only is that theory inconsistent with what has just been pointed out by Mr. Ferguson, but there is another little point on

which I am somewhat at issue with Mr. Wall and that is when he refers to the neighbouring country of India, and contrasts the condition of ancient agriculture there with that in Ceylon. There is one circumstance which I might perhaps refer to, in the first instance, which has struck me very forcibly indeed, and that is that in all my travels in the South of India I was impressed with the fact that every—if I may so speak—item of agricultural civilization which Ceylon possesses has been borrowed from our neighbours in the South of India. I was exceedingly struck with that fact, clearly proving as it does that our agriculture here is the child of a parent which came from the other side of the water. I mention that merely as a preliminary to another circumstance. Mr. Wall has told us that there is no record in India of any tank earlier than the fourteenth century. But it should be remembered in the first place that the south of India overflows with tanks, that those huge tanks to which ours are rather a contrast in point of magnitude, then existed and that the records of India have always been in a more imperfect condition than those of Ceylon. It is, I believe, a fact that Ceylon has the proud advantage of being in possession of records older and more authentic than any that are to be found on the continent, and, that may well account—in fact must necessarily account—for the absence of records in India of tanks older than the fourteenth century. When we see the whole of the South-East especially of India covered with tanks of the most enormous magnitude, and when we see that the only civilization that ever has existed in Ceylon, namely, agricultural civilization has been evidently borrowed from our neighbors, I think these facts suggest a considerable amount of modification of the theory which Mr. Wall has so ably endeavored to put forward.

Mr. KRISHNAN MENON (of the Madras Agricultural Department) remarked that Mr. Wall had attempted to show by an elaborate process of induction that there was a great development of national industry in Ceylon before Wijayo's conquest. To those who had been accustomed to accept the traditions and histories written by Sir James Emerson Tennent and writers of the same stamp, the theory propounded by Mr. Wall, that there were industry and civilization in Ceylon before the Wijayan conquest was startling; but to one who comes from India, who has been nursed in the legendary tales and folklore of his native country, who has had opportunities of studying the great epic poems in the vernaculars, the theory suggested by Mr. Wall will not be startling. Both the great epic poems of the Hindus—the Ramayana and Maha Bharat—were composed long before Wijayan period, and they contained references to Ceylon, which show that the inhabitants had at that period already attained a high degree of civilization. He agreed with the lecturer in thinking that Ceylon had a civilization before the Wijayan conquest. As regards the tanks, he did not believe that Wijayo and his followers brought with them the genius for tank-building because Wijayo belonged to the kingdom of Bengal which is inundated by the Ganges. He could not, however, agree with the lecturer in thinking that the ancient Indians were ignorant of tank building. The Aryan races were probably ignorant of it because they had no necessity for tanks, but the Dravidians, who included the vast majority of the Tamil population, knew a great deal about tank building, and the ancient kings encouraged and multiplied the building of tanks all over Southern India. It is therefore quite probable owing to the close proximity of Ceylon to the South of India that the Ceylonese learned the art from the Dravidians. (Applause.)

The CHAIRMAN:—I feel inclined to say a word, though I occupy a position which, unfortunately, makes it almost impossible for me to argue in detail upon the points raised by the previous speakers. Mr. Wall's most able and ingenious paper rests apparently upon the foundation of an implicit reliance upon the details of the Sinhalese chronicles, or at any rate upon their general veracity from the date 545 B. C., and what we want is to have some grounds for that confidence, other than the very general statements of the distinguished Turnour that those chronicles are worthy of credence. I imagine that Turnour said that, and that he said that they were furnished with all the evidence by which a history can be confirmed, not in reference to the earliest part of those chronicles, but with reference to them in general and with particular reference to their later part and to the striking confirmation to which he himself had drawn attention from the date 250 B. C. From the time of Asoka there is confirmation of the Sinhalese chronicles, but I am afraid for the 290 years before that we have still to find the evidence. The chronicles were written by people, say, 400 or 500 years A. D. who evidently had access to some records—faithful records—running back to 250 B. C., but there, as far as I am aware, all that we know ends. We have no reason to believe that they had anything further, though they may have done so. But as to their coloring of the details—the amount of gold or jewels, the number and names of the persons, etc.—those must be put down to the imagination of the writers of about 400 A. D.; at any rate what is wanted before we can follow the reader of the paper into all his conclusions is some further ground for believing that the writer of the *Dipawansa* had access to authentic materials for the sixth century B. C. I feel bound to draw attention to that which seems to me to be the weak point of an ingenious argument which unless further established by materials to be produced, seems still to be like founding historical conclusions upon the details of romance. When we meet with people who were said to be the grandsons of lions and who were like Ulysses and Calypso, themselves the guests of ladies of a supernatural race, we are naturally led to distrust the details of such a story. The strongest point which I think Mr. Wall has alleged is the mention of a tank comparatively a few years after the time assigned to Wijayo but still as that tank is not identified it appears to me to be the easier course to suppose that to be entirely fictitious than to suppose that it is a confirmation of the statements that surround it. No doubt as our valued visitor has pointed out Wijayo coming from the North of India was not likely to have introduced a system of tank irrigation into this country and if only 40 or 50 years after his arrival his successor made a tank it is pretty certain that there was developed a knowledge of the system in this country independent of his arrival. That would be a most interesting confirmation of the degree of civilization that existed if we had proof that his statement is historical, and I hope that Mr. Wall, in the next paper, will direct our attention especially to the further proofs which I am sure he has upon which he rests his confidence that history may be based upon those parts of the *Dipawansa* and *Alchhosansa*.

Mr. GEORGE WALL:—My Lord, Ladies and Gentlemen, I was afraid when I began to read my paper that I was already trespassing rather too much upon the patience and good nature of my audience. Had it been otherwise I should not have contented myself with the proof or evidences that I have adduced, but I should have endeavoured to anticipate points which will be brought upon a future occasion

which show that the hypothesis which I have ventured to propound is not dependent upon mere details but upon the substantial facts of history. I quite agree with the gentleman who said it was a startling one because I felt it so myself and it was not until I had seen that it was supported by accumulative proof that I accepted it. If it had depended upon a single statement here, or a single parenthetical remark there, gleaned painfully from small details, I would not have troubled this audience with it; but, having started the enquiry long ago with the belief generally entertained, namely, that this country was inhabited by aborigines, and that the period of authentic history was the period of civilization, and that civilization commenced with it—it was not until I found how strangely inconsistent that state of affairs was with the whole pile of history that confronted me that I changed my opinion, which was based in part upon what the exports and imports, according to Tennent, were at the time we had been alluding to. It is with regard to the condition of the island at the time of Wijayo's landing that we must look to as the starting point upon which the theory depends. Now, according to Sir Emerson Tennent—page 416 first volume, the only exports were gems, pearls and chanks. I have taken the trouble to count up all that should be, according to the knowledge we now possess, obtained by gems, pearls and chanks, and then I set against it what we were supposed to have imported—slaves, chariots, horses, gold, cloth, frankincense, sandalwood, silk, vermilion, woollen cloths, and carpets, gold and silver. He says that the gold which was lavished upon the cupolas of the Dagobas and which abounded in the vessels that were used must have been imported as it exists here so scantily. We are said to have also imported the only grain there was. Be it observed that is the only argument, and I can find no other arguments in favor of the theory that Ceylon had no grain. It is distinctly stated, in so many words, that, not only at the time of Wijayo's landing, but for several centuries afterwards; Agriculture was not known and that grain if grown at all was not systematically cultivated till several centuries afterwards. The only argument in proof of that stupendous conclusion, so far as I can find, is that the rice was obtained from wrecked ships, but whether there is any people that ever were kept in food by the chance of a precarious advantage of wrecked vessels, I leave this audience to judge. (Laughter.) The fact of that little parenthetical observation about wrecked ships is quite consistent with the facts of everyday occurrence. I suppose, if a ship laden with rice, were wrecked, we should not object to using the rice if it were not seriously damaged; but the idea of a population such as I have demonstrated should have existed depending upon rice from wrecked ships is too absurd. The other evidence adduced is that in a present that was sent from the neighbouring continent, there were a great number of grand things. I can hardly enumerate them all but they were about the greatest luxuries you can imagine in your wildest oriental imaginations. There were one hundred and sixty cooly loads of what? Hill paddy. Now, what practical accompaniment would such an item be along with that glorious canopy and golden horses, chariots, and that sort of thing. I consider it would not have been sent if it was a present of rice in such quantity as would have been devoured in a single week. It was hill paddy, and I conclude that it is a hill rice, not a lowland rice. I suppose that hill paddy was not generally known in this country especially cultivated, and that, seeing that they were painfully cultivating the rice that they

consumed by a process that required such tremendous tanks, it would be a great boon to this country to have a kind of rice that would grow on mountain sides and dry places where water was not accessible. At any rate I draw no conclusion, and I should consider a hypothesis built upon such evidence as not worth very much. I would draw my conclusion in some proportion to the facts, and the hypothesis I put forward is necessary in my opinion to the whole narrative. Not only must you discard all the details but you must discard the whole thing unless to make it consistent you invest the island with a previous history to that of the time of Wijayo, it will hereafter be my endeavor to show that that tank was the first tank of the kind. I may say, in anticipation of what is to follow, if these great works had been the work of Tamils, I appeal to this audience to consider whether the Tamil monarch Panduwo would have allowed them to go out of his possession, or whether it would not have been maintained with the same regard that a British Government would regard the vast sum of money that it had expended on any public works, and whether, if we erected those tanks, we would quietly have allowed the people to claim them, and taken no further notice. Now, these monarchs, Panduwo and others, were close neighbours, and I look upon the part that these neighbouring monarchs played as the most incontestible proof of the independent action of this country. As I said, the problem as to who the then Sinhalese were is a problem which does not concern my inquiry, and is probably beyond my powers to solve. I see certain broad facts which meet me at every turn, and I may say that I have read Tennent's book over and over again, the *Mahavanso* and other books, and endeavored to harmonize the old and accepted doctrines, and it defies all my power. When I see such a small list of exports and such a prodigious list of imports, it calls upon me to believe that this country was so poor that it could not feed itself, but was yet so rich that it could import all the luxuries of the world! It appears to me, my lord, that the groundwork was at fault, that the hypothesis, that this country was inhabited by a few aborigines and that Wijayo commenced the history of civilization, is a mistake, and that it is impossible to harmonize facts which required these tremendous—these stupendous—conclusions from those very slender premises. With regard to the remark of Mr. Ferguson, I must reply that I have not had the advantage of reading much poetry (laughter)—that is not in my line quite—but in my reading I may have been singularly fortunate for the only poems that I have ever found it worth my while to read or had the means of reading, because they were translated into English, were the most beautiful expressions of womanly devotion and virtue that I could have addressed to my own daughter. (Applause.) I do not doubt for one moment that, along with these, there were others of a very different character which co-existed, but those ideas prove that there was a high culture, that there was refinement. There may have been along with it that which was very debasing—so there is amongst ourselves, alas and alas—but you do not therefore disparage the poet because there are some who have disgraced the language. I am sorry it did not occur to me, my lord, to bring a copy which I made of one of these poems, intending to read it, but, fearful of taking up more time than was meet, I have curtailed my paper and did not bring forward more than was necessary.

Mr. FERGUSON:—Would you kindly mention where we can find those verses?

Mr. WALL:—In the Sidat Sangarawa I believe that the poems I allude to must have been translated by

Mr. Skeen, because I find that they were signed W. S., but my attention—

Mr. THOMAS BERWICK:—What is the date of those verses?

Mr. WALL: I cannot give you the dates. I have not introduced the subject further than that there was refinement, and the dates will be given when the paper is printed. I think Mr. Ferguson did not mention the date of his specimen. (Laughter.) I think, if the system of tank cultivation had been as well known in India as it was here, the King of Cashmere would not have sent through and passed his own neighbours to find engineers in the eighth century of this era to carry out works of a similar nature. The fact that our works and those of South India are in many respects similar, I think, does not prove that the Indian necessarily preceded these. I think they may have been originated here for any argument that has been adduced to the contrary. Further than this, we shall see more hereafter. In regard to what has fallen from his lordship, as I say I gleaned my hypothesis from a general consideration of the narrative and not from its details only. With regard to Asoka, of whom, it would appear from his lordship's statements, that history would be more reliable, he, in sending his present to Ceylon spoke of this island as a splendid country and exclaimed, after he was given the presents from Ceylon, that there were no treasures to compare with them in those parts. I am sorry, my lord, to have taken up so much time, but the subject is one of some interest, and I hope I may be pardoned for having done so.

CACAO PLANTING IN CEYLON: A REVIEW.*

(Communicated.)

The general public have a fair ground of complaint against you for consigning the able and exhaustive lecture of Blackstone Barber, teeming as it is with matter of deep interest socially, politically, scientifically and agriculturally, to the comparative obscurity of the *Tropical Agriculturist*. Do not tell me that this useful publication has a wide circulation and is filled for reference in every Kacheheri. I know that, but as general circulation is less locally than that of the *Observer*, and it is consulted only by those who are directly interested in agriculture, and even then to a limited extent comparatively. [This is a reflection on the community: we take it that no intelligent man interested in the planting industries of the country fails to glance through each monthly *T. A.* If so, so much the worse for him!—Ed.]

The planting community, European chiefly, is more beholden to Mr. Barber than perhaps to any other single planter in the island, while to his countrymen of the younger generation he is a shining light, a bright example to be followed by all who wish to carve for themselves a name and reputation. Messrs. Wright and Barber are examples of what the Ceylonese are capable of when engaged on their own account in the cultivation of products which engage the attention chiefly of Europeans, and in competition with them.

Though Mr. Barber's paper professes to deal with cacao, it wanders incidentally to all the products that are and can be cultivated in the lower spurs of our mountain ranges. Matale is specially favoured with a very deep friable soil interspersed largely with dolomite. One drawback there is however, and that is its dry climate. Given facilities for irrigation and there is no limit to the agricultural capabilities of Matale.

* Cacao Planting in Ceylon; with Hints as to the Best Varieties to be Cultivated: A Lecture Delivered at Matale on the 30th June 1888 by Mr. J. H. BARBER; with Additional Hints on the Best Varieties and Useful References in Appendixes. Colombo: Ceylon Observer Press, 1888.

In enumerating the products that can profitably be cultivated in this fruitful valley, Mr. Barber seems to have forgotten fruits and vegetables. Male oranges enjoy quite a reputation for their lusciousness, while vegetables, Ceylon vegetables, and plantains attains great perfection there. As to arcanuts, Mr. Barber's opinion hardly coincides with that of Mr. John Ferguson, who, professing to reflect the opinion of planters generally and of the proprietor of Crystal Hill particularly, in his recent notes of a trip through Matul and Laggala wrote: "As regards aracas, the only fear in the neighbourhood of Male is of the rainfall not being sufficient;" while Mr. Barber says: "The graceful araca palm, shading the humble homestead of the poor villager, flourishes here with a luxuriance that is matchless." These contradictory opinions can be reconciled only by supposing that Mr. Ferguson refers to the hill-slopes where European cultivation is carried on, [Quite so.—Ed.] and Mr. Barber to the damp, shady valleys, the residences of the villagers. Shade and moisture are essential to the successful cultivation of the araca palm, and on plantations they are not likely to flourish except in the vicinity of swamps and ravines.

Mr. Barber complains, and justly, that in undertaking the cultivation of new products we are at a disadvantage owing to the scantiness of the information accorded us by the Botanical Department of Government. The Dr. Trimen when applied to is ready to impart all the information at his command, but that benefits individuals only. And in his Administration Reports a good deal of information on all products is vouchsafed, but these useful publications are annual. We want general information on all subjects engaging the attention of planters, and on products that might with advantage be cultivated by them, oftener than once a year. If a "Ceylon Botanical and Agricultural Bulletin" cannot be undertaken, the Director might copy the example of Mr. Morris, late of Jamaica, and through the press draw the attention of planters to products that might be profitably cultivated by them, and impart information on the cultivation of products already undertaken by them. The absence of cubeba (*Piper Cubeba*) in our Botanic Gardens is drawn attention to, but it is a satisfactory to learn that Dr. Trimen is endeavouring to obtain seeds of this very valuable pepper from Java. [Again we say there are Dr. Trimen's Annual Reports and the *T. A.* monthly, full of hints about new products.—Ed.]

In enumerating the districts in which cacao is grown, mention is made of the Negombo district, from which remarkably fine pods were obtained from Mr. F. Driberg. The estate in question is at Ekele, and is one of the original common plantations of the Dutch, and the soil of it is the usual white sand of the common gardens. The trees which yielded the pods were raised from a seed pod purchased at Hemmatoda. I believe some old trees of the red variety were standing on the site of the present bungalow and had to make way for it. Reference is made to old trees of this variety growing at Small Pass and Kalutara to show that even with no special attention cacao trees attain a great age. On Mr. De Brecht's grounds at Grandpass stand two old trees which year after year yield a good harvest of pods, which were turned into chocolate by the late Mr. De Brecht, an eminently practical man, long before cacao cultivation attracted attention. There was a discussion a few years ago in the papers as to the source of the seed for Mr. Tyler's plantation at Demerara. It was decided then I believe that the trees standing on the premises now occupied by Mr. Venning in Kandy was the parent tree of the original plantations. All this goes to prove that cacao is as long-lived and as permanent an industry as coconut cultivation. The much vexed question is, what is the great danger, as to the superiority of the two red varieties of cacao, *Forastero* or the red? The *Forastero* is the harder tree and is more easily grown, but it is coarser than the red *Forastero* which is very delicate and has to contend with many enemies. It however helped to give Ceylon the splendid

reputation she enjoys for the fine quality of her cacao. The question narrows itself into whether for the sake of better prices we are willing to face the heavy initial expense and disappointments of planting a garden with the delicate red variety, or whether we will be content with lower prices for a variety that is hardy and can easily be raised? The solution of the difficulty, it is contended, lies in the possibility of obtaining a hybrid to combine "the excellence of the *Caracas* with the hardy habit of the *Forastero*." To a cautious mind it does sound extremely rash for Mr. Barber to assert without qualification that the pink *Forastero* is "undoubtedly a hybrid." It is better that such a difficult question as to whether a plant is a hybrid or a distinct variety,—a question sometimes on which eminent scientists are not agreed, be left to the decision of a specialist like Dr. Trimen. It will be interesting to know what his opinion in the subject is. The subject is one of the highest importance to cacao planters. Mr. Barber's keen, enquiring mind discovered that there is a peculiarity in the colour of the seeds of the so-called hybrid, that it is pink in colour or a cross between the white of the *Caracas* and the purple of the *Forastero*. Mr. Barber's favourite variety is the pink *Forastero* which he is pleased to call a hybrid. The gentleman who supplied Mr. Barber with this variety affected the long green Maravilla, and wished him by comparison on the spot to satisfy himself that the latter was superior to the former. The invitation was accepted, and Mr. Barber with the discrimination due to his legal training refused to accept as conclusive the inferiority of his favourite till the two varieties received searching tests. Average sized pods of both varieties were secured and submitted to the test of weighing. It was found "relatively, in proportion to the weight of the husk, there was a preponderating weight of seed in the hybrid over the Maravilla." The seed too in each pod of the former weighed more than the seed in the latter. The Maravilla had the larger number of seeds, which consequently gave the advantage in size to the hybrid and increased its value. It may be interesting to know the history of this so-called hybrid. Mr. William Rollo, at one time Visiting Agent of the Ceylon Company, imported from Trinidad two cases of cacao plants. Mr. Ferdinandus of the Botanical Gardens received one of the cases and successfully raised a dozen plants from it in his garden at Kadugannawa (?) One of these happened to be the pink variety, and is the parent of the trees now growing at Wariapola and Dumbara. This pink variety does not occur in the group of *Forasteros* in the Botanic Gardens received from Kew in 1880.

AFRICAN PALM OIL NUTS

are becoming quite plentiful in many districts in Ceylon, and the question will specially arise as to how they are to be utilized either for export as plucked, or by having the oil locally expressed. We are told that "the oil is obtained from the African oil palm nuts by means of a process of boiling, and not by machinery such as is used for coconut oil." Just as we are writing, we find in the *Indian Agriculturist* the information we want as follows:—

THE OIL PALM. The British Consul at Lomé in a recent report on the agriculture of the provinces of Aghida, describes the method of obtaining palm oil, the great staple of trade along the rivers of Western Equatorial Africa. The palm from which the oil is obtained may be said to be a wild product of these regions and requires no planting; yet it receives a certain amount of attention at the hands of the natives in the shape of pruning, tapping, and drying leaves, and tapping, some of the stronger leaves, with the object generally, it is presumed, of improving the fruit. The latter grows in large clusters, nearly pear-shaped or somewhat like a huge branch of very small red grapes, and clusters contain perhaps a thousand nuts, which are partially embedded in a kind of fibrous matting. The nuts and fruit are the size and nearly the shape of a pigeon's egg, of a bright red colour,

tinged sometimes with yellow, and in some cases deepening in shade almost to black. The nut is composed of three parts, the outer covering, the hard nut, and the inner kernel. In this respect it is like a plum. The outer covering is from an eighth to a quarter of an inch in thickness, of a fibrous nature, and in this is the oil. To extract the latter, the nuts are boiled and beaten to separate the oil from the fibre, which is then skimmed off, and put away in pots ready for sale, requiring no further preparation. The inner nut is cracked and the kernel, which produces a fine white oil, is sold. A few years ago oil from Angola sold in Europe for about £40 a ton; it has now gone down to £20, and there is said to be no prospect at present of an improvement in the price, because so many substitutes of a cheap kind, notably petroleum are now employed in manufactures such as soap, candles, etc., where at one time palm oil alone was used. The meal of the kernel, after the oil is pressed out, is used to make seed-cake for cattle. The oil is also used as an article of food, but it is then subjected to a little more refining than when it is intended for commerce. This African palm grows so readily almost everywhere in Ceylon that it may come to rival the coconut and palmyra; indeed exceed both in its ready growth. The "Encyclopædia Britannica" says:—"The seeds of *Elais guineensis* of Western Tropical Africa yield, when crushed and boiled, palm oil." "Chambers's Encyclopædia" says:—"The pulp of the drupes forming about three-fourths of their whole bulk, yields, by bruising and boiling, an oil" &c. Again, "The nut was formerly rejected as useless after the oil had been obtained from the fruit; but from its kernel a fixed oil is now extracted [Not said how, so we infer expression.—Ed.] called palm nut oil; which is clear and limpid and has become to some extent an article of commerce." "Unripe nuts make excellent soup!"

DRUG TRADE REPORT.

London, November 1st.

QUININE FOR THE MILLION.—It appears that a well-known London quinine operator is now trying to popularise quinine among the natives of India, Burmah, &c., by offering to supply "direct to the consumer" 4-grain quinine pills in boxes of two each, twelve boxes done up in a larger packet, at 1s for the twenty-four, which is equivalent to 4s 6d per oz. Buyers who order 1,600 small boxes, or about 80 oz. quinine, in one order, will receive the goods carriage paid to any part of India. Each packet is accompanied by an illustrated pamphlet of 16 pages, giving information in Marathi, Tamil, Gujarati, Bengali, and Hindustani, with pictures of various public buildings in England to "catch the native eye." Particular attention is called to the fact that the pills are "made by machinery."

ANNATTO.—A little firmer. Some fairly good Brazilian Roll annatto was offered, and sold at 1s per lb., and for a parcel of East Indian Seeds 3½d per lb.—rather a good price—was paid.

CARDAMOMS.—Only a small quantity was offered for sale today, and mostly disposed of, with excellent competition, at an average advance of fully 2d per lb. for fairly good lots, which formed the bulk of the supply. Ceylon Malabar, good pale round, medium to bold, 1s 10d; rather smaller and yellower, 1s 8d; small to medium fair yellow and warty, 1s 6d to 1s 7d; very small round, 10d; husks and split, 5d to 7d per lb. Mysore, fair medium to bold pale round, 2s; long pale medium to bold size, 1s 9d; medium and small mixed, 1s 5d; small, 2s 2d; very small thin pale, 9½d to 1s per lb. Seeds sold at 1s 4d to 1s 5d per lb. Aleppy, fairly good brown, 11d to 1s. Thin small Tellicherry held at 4d per lb.

CINCHONA.—South American barks were in small supply today, and none were sold. Two boxes of flat red bark (South American) were shown, one (100), containing exceptionally fine bold red pieces for which

10s or 11s per lb. is required, the other (56 lb.) of good colour, but broken and dusty, was bought in at 4s 6d per lb. The total exports of cinchona from Java during the month of August were 262,452 Amst. lb. This was all grown on private plantations, and about one-fourth of it has been sent to London, the rest going to Amsterdam. Mail advices from Ceylon stated that the season just closed has been remarkable for the collapse of public sales throughout the year; and that there is little doubt that on many estates the cultivation has been given up entirely in favour of tea.

CROTON SEED.—A small lot of fairly good pale Ceylon seed was disposed of today at 18s per cwt., which shows some improvement.

QUININE.—A large business, amounting to over 200,000 oz. is said have been transacted since last week at advancing prices, the rise being between 1d and 1½d per oz. since the date of our last report. Whether the quantity reported as having been sold has actually changed hands it is, of course, impossible to say; but there seems no doubt that a considerable movement has really taken place. The B. & S. and Brunswick factories are said to have been the principal sellers. The former works now quote 1s 6d to 1s 6½d for delivery early next year, and they claim to have actually made sales at the lower figure. Whiffen's, Jobst's, and Zimmer's brands are quoted at 1s 6d per oz. in bulk; Howards' and Pelletier's brands remain unchanged. It is not, of course, an easy matter to give the precise reasons for every small fluctuation in the article, and the only safe guide to the future is, we are convinced, to entirely leave out of account the manoeuvres of different speculators. We hear rumours of all kinds concerning these operations, such, for instance, as that the London agency for a foreign manufacturer recently sent large quantities of quinine bought here back to the Continent for the purpose of being repacked and then tendered to buyers in fulfilment of contract. But rumours of this kind are always in the air, and no great importance should be attached to them.

VANILLA.—The latest mail reports from Mauritius state that the outturn of the coming crop in that island will be a small one, and is not expected to exceed 34,000 lb. At today's auctions over 200 tins were offered, and nearly all sold at good to slightly dearer rates. Common long, 8s to 9s; ordinary small and brownish, slightly crystallised, 5s to 9s; good chocolate, 4 to 7 inches, 6s to 10s; 7 to 7½ inches, 11s 6d to 14s; 8 inches, 18s to 19s; fine, 8½ to 9½, 28s. A large parcel of very ordinary beans, said to be salvage from the Yorouba, but resembling very nearly the pods from the African West Coast which we noticed in a recent issue, sold at 5s to 6s 6d for the best, and from 2s. to 1s 1d per lb for the commonest lots.—*Chemist and Druggist*, Nov. 3rd.

TROPICAL FRUITS.

(From the *Kew Bulletin of Miscellaneous Information*.)
DOMINICA.

The following interesting and valuable Report on the fruits of Dominica has been prepared by Dr. H. A. Alford Nicholls, F. L. S., Government Medical Officer, and a valued correspondent of *Kew*:—

From the time of its settlement Dominica has been justly celebrated for its fruit. Of all the British Possessions in the Lesser Antilles it is now regarded as having the best promise of the development of a large and remunerative fruit trade, not only with the United States and Canada, but also with Europe. The islands lying between Dominica and the mainland of North America, with the exception perhaps of the small colony of Montserrat, are not adapted for the cultivation of most of the tropical and sub-tropical fruits, by reason of the droughts to which they are sometimes subject. Thus it happens that Dominica is the nearest fruit-producing island of the Lesser Antilles to the United States and Canada, and it is also the nearest of the West Indian fruit islands to Great Britain. This is an important fact in regard to the future of the fruit trade between Great Britain and

North America and the Lesser Antilles, for with so perishable an article as fruit even a few hours curtailment of an ocean voyage means sometimes all the difference between profit and loss. Possessing a fertile soil, unsurpassed in any other part of the world, an abundant rainfall, and a wide diversity of climate, owing to the mountainous nature of the country, the capabilities of Dominica for the culture of tropical and sub-tropical fruits can scarcely be over-estimated. There can, therefore, be no doubt that when the natural advantages of the island become more widely known, the necessary capital will be found to form farms for the growth of the various fruits and vegetables that can be exported at a profit.

The earliest recorded instance of a trade in Dominica fruits is found in Atwood's history of the island, published in London in 1791. Atwood says, "The Lemon and the lime trees bear also very aromatic scented blossoms, and the fruit of both is in great abundance, large and of excellent quality. Of these, the latter especially, great quantities are often sent in barrels to England and America. The neighbouring English islands are likewise often supplied with them from this country, especially those of Antigua and Barbados." What the old historian of the Dominica wrote nearly a century ago is true even now, for quantities of the island fruit are exported not only to England and America but also to many of the neighbouring islands. It was not, however, until recent years that fruit became a regular article of export from the Colony, for the successful prosecution of such an industry requires experience in what is styled "the handling" of the fruit, experience also in the various systems of packing, and a knowledge of the requirements of the markets abroad. In past times American schooners used to come to Roseau, the chief port of Dominica, for oranges, but owing to ignorance of the buyers and sellers the ventures did not pay; and it is scarcely to be wondered at, as the oranges were knocked off the trees, and the bruised fruit was shipped roughly in bulk in the hold of the vessel, with the result that most of it became rotten long before its port of destination was reached. As a case in point it may be mentioned that the Blue Books show that in the year 1851 the fruit exports from the island are estimated at 703*l.*, which sum includes 115*l.*, the value of the Lime juice exported that year. With the exception of 1,019,800 oranges shipped to the United States, and valued at 489*l.*, there are no details given of the kinds of fruit exported; and as no more oranges were shipped to America until many years afterwards it must be assumed that the venture was not a paying one. About 14 years ago, with a view of demonstrating the capabilities of the island for a fruit trade, I made a few trial shipments of oranges and shaddocks to Messrs. Keeling and Hunt, of Monument Yard, London. Notwithstanding the long voyage by the Royal Mail steamers, longer in point of time than it is now, and the transshipments at Barbados and St. Thomas, the fruit, which was carefully selected and packed, arrived in London in excellent condition, and fetched the highest price in the market, where it was then somewhat scarce, and as a consequence the results of the shipments showed a large profit on the outlay. I showed several of our local merchants the account sales, but nothing was done to promote the trade, and things went on in their usual style, for oranges appear in the official lists of exports for the years 1876 and 1877, and they then disappear again, as might be expected, for the shipments could not possibly have paid owing to the rough handling of the fruit. Probably there would have been no considerable fruit trade in Dominica now but for the enterprise of some Americans who came to the island in the proper season, brought up oranges and other kinds of fruit, and shipped them to the New York market. These Americans went the right way to work. They refused to purchase oranges that did not have the stalks attached and properly cut, and in this way they ensured, to a great extent, the proper hand-picking of the fruit. They insisted with resolute alacrity on fruit, and when they bought they packed carefully in suitable boxes, each orange having

been examined for bruises, and if found sound wrapped in paper specially imported for the purpose. The result was a revolution in the desultory and insignificant fruit trade of the island. The Americans came back year after year, thereby showing the people that the trade was successful, and then local men began to take up the matter, with the result that at the present time the Americans have to compete with resident shippers.

With the exception of the Limes, which are extensively grown in the island for the sake of their juice, and the bananas which are cultivated by the peasants, the greater part of the fruit shipped from the island is gathered from trees that have grown up, in most cases accidentally, in gardens, in odd corners of estates and by the roadside. Considering that the exports of fruit, excluding lime juice and other fruit products, now reach in value a good deal over 1,000*l.* a year, or about one forty-eighth of the total value of the exports of the island these facts are very striking, and they are pregnant with promise for the future of the trade. Some of the planters and peasant proprietors are now turning their attention to the systematic cultivation of oranges, shaddocks, and other fruit trees on a small scale, but the only estates in the island devoted entirely to fruit culture are those belonging to the lime planters, who do not, however, ship the fruit in its natural condition in any considerable quantity.

The chief fruits exported from the island are oranges, coconuts, bananas, limes (both fresh and pickled in brine), mangoes, shaddocks, and pineapples. The tamarind is exported in a preserved state, but it is only when the prices are high in the home market that local shippers consider it worth their while to ship this article, and thus the quantity exported varies considerably year by year. The juice of the lime (both fresh and concentrated) has become a very important export from the island, and any account of the fruit trade would be incomplete without some details of the industry, which was started in Dominica years ago by the late Dr. Inray, to whom the island owes, on that account alone, an everlasting debt of gratitude. The lime, which is the fruit of a tree closely allied to the orange and lemon, has done much to help to revive the prosperity of Dominica; and, as the industry is constantly growing, it gives promise of great things in the future. In addition to the juice of the fruit, very fragrant essential oil, called commercially the "essential oil of limes," is obtained from the rind of the fruit. This oil is not yet very well known in the trade, but the demand for it is increasing, and the exports of the article are accordingly running up in value. Besides lime juice, other fruit juice has been exported by one of the planters during the last two years. The principal kind is that obtained from the pineapple. It is shipped principally to the United States, and it is used for flavouring purposes.

In order to give a correct idea of the fruit industry in Dominica, I have made a careful examination of the Blue Books kept at Government Office, but as the volume for 1880 is lost, and as no other copy exists in the island, I have been unable to go back for more than seven consecutive years.

As will be seen from this table, the total value of the exports of fruit and fruit products for the seven years amounts to the sum of 46,030*l.* 9*s.* 10*d.* Since it has not been possible, for the reasons given, to obtain any statistics for the year 1880, I have drawn up the following table showing the value of the same articles exported during the seven years ended 1879, and a comparison of the two tables will conclusively show the satisfactory progress made in the prosecution of the fruit industry as well as indicating the principal commodities that the shippers and exporters have had to contend with.

Until the year 1880 the value of kinds of fruit exported from the island was not recorded in the official returns, but, one of the main objects, were all included under the heading of "fruit" or "fresh fruit and vegetables." I pointed out, however, in 1880 to Mr. U. Murray, the chief clerk in the Treasury Department, the advantage for statistical

purposes in keeping proper records of the progress of a new and growing industry, and since then that gentleman has entered the fruit exports in detail in the Blue Books. Thus I have been able to compile the following interesting table, which shows the kinds of fruit exported during the last two years, their estimated value, and the countries to which they have been exported.

This table shows that a considerable trade in fruit is carried on between Dominica and the neighbouring islands—English, French, and Danish, more especially those lying between Dominica and the United States. Indeed as far as the northern Islands are concerned Dominica may fitly be described as their orchard. The commencement of a trade, too, has been made with the United Kingdom; and, as I understand that the fruit shipped to London was, in most instances, sold at a profit, it is to be hoped that there is here the germ of a regular trade between the mother country and this fine but neglected island. As will be noticed from the table, nearly half of the total exports goes to the United States, the Quebec Steamship Company and their officers having done all in their power to facilitate and to foster the trade, and I would here remark that it is to be regretted that the Royal Mail Steamship Company are not equally anxious to foster this local industry.

Particulars of the fruit exports are given in the table under nine heads, but two of them, namely, limes and pickled limes, are essentially the same, the latter being simply ripe limes packed in brine, which preserves them remarkably well for a long time.

The following are the average prices from which the values have been officially estimated:—

	s.	d.
Bananas, per bunch	0	6
Coconuts, per barrel	8	4
Fresh limes, per barrel	7	6
Pickled limes, per barrel	8	4
Mangoes, per hundred	1	0
Oranges, per hundred	1	0
Pineapples, per barrel	8	4
Shaddock, per barrel	8	4
Non-enumerated fruits, per barrel	5	0

It must be remembered, however, that this valuation is for fruit properly pickled, selected, and packed, ready for export, and it includes the cost of packages and packing. In bulk the fruit can be bought much cheaper. Thus, selected and hand-picked oranges can be purchased at 9d. a hundred, and limes at 4s. a barrel, and it would doubtless pay some London fruiterer to visit Dominica in the fruit season in order to buy up fruit for export.

Under the head of "non-enumerated fruits" are included a great number of various kinds other than those mentioned in the eight foregoing columns of the table. Perhaps, for its size, Dominica produces a larger and more varied number of fruits than any other part of the tropics. I have made the following list of 60 kinds of fruit that are grown in the island; and, in order to make the list as useful as possible, I have given the local names, the botanical names, and the habitat of the plants producing the fruits, as well as the season during which each kind is plentiful, and I have added such special information as appeared to me to be necessary. Each plant has been placed under its natural order, as such a classification is perhaps the easiest for reference.

HINTS TO BRITISH MANUFACTURERS.—Ceylon tea planters continue to give attention to the utilisation of petroleum for fuel, and petroleum-driven engines are consequently growing in favour. The daily erection of tea stores, and the probable scarcity of wood fuel in a few years, make the question an important one, though it is likely that Siam and India will be able to supply suitable coal ere-long; but, as already pointed out in this column, petroleum fuel would be very largely consumed in Ceylon tea factories if the odour, which is its chief characteristic, could be dispelled. —*Colonies and India.*

SIAM.—We had occasion to remark the other day on the development of the internal resources of Siam; how a Syndicate had been formed to open up new lines of railways and other enterprises in connection with prospecting for minerals. If any thing speaks well for the welfare or prosperity of a country is its external trade, and in this connection Siam has made great strides in exports. The quantity of rice sent out of the country during 1887 is by far the largest yet on record, being 402,048 tons, the next being in 1881 with 274,300 tons. Teak takes the second place among established exports. It shows, however, a falling off 47 tons as compared with 1886, the best year hitherto. Pepper shows a considerable increase with a total of 1,553 tons and very nearly brings the export up to the maximum point of 1883 when the figures were 1,571 tons.—*Indian Agriculturist.*

THE AMERICAN PEPPERMINT CROP.—Mr. G. W. Osborn, of Parkville, Mich., U. S. A., writes that on September 22nd the peppermint crop in his State had nearly all been distilled, and, through want of rain, has yielded less than was expected, 30,000 lb. being the highest estimate for St. Joseph, Cass, and Kalamazoo counties. The prospect is that there will be but half the present acreage next year, and the planting will be confined to a few favoured localities on marshes and other low lands. When the price is less than two dollars per lb, its production on upland will decrease. In Michigan State there are said to be one acre of lowland to ten of upland soil under peppermint cultivation, but in the State of New York mint is principally grown on lowlands. With reference to the alleged adulteration of American with Japanese peppermint oil, Mr. Osborn says:—The exports of Japanese oil from Japan in 1884 were 12,020 lb., in 1885 20,480 lb., and in 1886 81,330 lb. The first export to the United States appears to have been in 1885, and amounted to 665 lb., but it increased in 1886 to 2,797 lb. This probably was the commencement of its use as an adulterant for American oil, and there is no doubt but that 81,000 lb. of oil are being used as an adulterant to the detriment of consumers and producers, hence the poor quality of oil sold to consumers since my last communication.—*Chemist and Druggist.*

DESTRUCTION OF CASUARINA TREES.—In a motion by Mr. Short, Attorney-at-law, at the High Court yesterday, it was mentioned to Mr. Justice Kernan that the recent storm had caused great damage to a plantation of Casuarina trees situated at Kunoothoor in the village of Wooduntee, from 20,000 to 40,000 of them having been broken down by the force of the wind. As these trees were the property of an insolvent named Yarlagudda Ramunna Naidoo and in mortgage, Mr. Short, on behalf of the mortgagee, applied for an order of the Court authorising him to cut, remove and sell them, so that a reasonable profit might be obtained by the transaction. Mr. S. Billigiri Iyengar appeared for Arcot Cundaswamy Moodely, the first defendant, also an insolvent, objected to the hurry displayed in desiring a removal of the trees which could result in nothing less than great loss to the mortgagors whose property amounted to Rs150,000 whilst the amount of the mortgage did not exceed Rs20,000 and that the statements of Mr. Short were not borne out by affidavit. This Mr. Short denied. Mr. Burton, on behalf of the Official Assignee, argued on the same lines against the motion of Mr. Short. Mr. Justice Kernan said that although the mortgagee was in possession of the property still, the mortgagor had every right to enter, cut, sell, and do what he liked. His Lordship accordingly passed an order that the Official Assignee in conjunction with the first defendant should appoint a proper guardian over the trees, and obtain the profits whilst the mortgagee should see that such profits were properly obtained, and all matters connected with the accounts fairly transacted. —*Madras Mail*, Nov. 14th.

THE PROMOTION OF NATIVE INDUSTRIES IN CEYLON: NUTMEGS AND PEPPER.

Over forty years ago, the gentleman who may be called the pioneer of the Sabaragamuwa district, planted during one of his many journeys up and down, some NUTMEGS in the grounds of the Rathnapura resthouse. The resulting trees have been the admiration of everyone visiting the place, and the resthousekeeper confesses to a handsome return for a long period back from the crops. As much as twenty rupees per tree have in some seasons been netted from the nutmegs sold, and this is a fact peculiarly within the cognizance of successive Assistant Agents of the district; yet what have they done to induce headmen or villagers to go in for nutmeg cultivation? Absolutely nothing. For over thirty years, probably, these trees have been bearing luxuriantly, and the seed (or part of it at least) which might so well have been utilized for nurseries, has all been sold in the bazaars; while so far as we know, no native garden of nutmegs is to be found in the whole of the wide-extending district of Sabaragamuwa, although the above—the finest trees in the island are everywhere—one can see them and under native and official care. It was left for the original planter to be the first to endeavour to profit by the lesson his own trees taught him, and it says much for his buoyancy of spirit and regard for posterity that Mr. Shand should, when quite 60 years of age, have planned to open extensive nutmeg groves on his Rakwana estates with the aid (readily rendered) of the Director of the Botanic Gardens. Unfortunately his orders at the time were not carried out as he wished; nevertheless there are now a good many flourishing nutmeg trees rising 7 years old, and showing signs of fruiting on Rangwellestene estate, besides several thousands of luxuriantly growing Clove trees. It may be said that the moral points more to the slowness of other and younger European planters not going in for these industries; but we are dealing now with paid public servants who are supposed to be promoting native agricultural interests, and who if they had got each village to plant 1,000 nutmeg trees might have done the people more lasting good than by pending months of inspection and reams of reports over possible or impossible paddy field restorations.

Take a far more important industry—that of PEPPER—which affects this same district, but still more the adjacent division of Kegalla—what has been done to promote and extend Pepper growing in Kegalla? How much does the district export? Why the export for the whole island last year was only 14 cwt. against 136,000 cwt. from the Malabar coast opposite; and yet pepper-growing was *par excellence* a native and a Sinhalese industry from time immemorial, and the very centre of cultivation from a period dating 300 years back has been the country between Hanwella, Kegalla and Rathnapura. Pepper was esteemed by the Dutch as perhaps the most suitable and most profit big of Ceylon products. In 1749 Governor Van Imhoff considered pepper better worthy of attention than coffee or cardamoms, the export being then 465,000 lb. per annum, and Lord Macartney at the beginning of the present century, declared that native indolence alone was to blame for the cultivation not being greatly extended, as "the pepper vine will grow on almost any soil and everywhere forest trees to grow over." This opinion as to soil may not be quite reliable, but there can be no doubt that if the servants of Government had interested themselves with their headmen and people to urge the cultivation of pepper in the

middle and lower Kanayan districts, this specially suitable industry would have brought more wealth to the Sinhalese than all the extensions of paddy-growing of the last half century. In our forthcoming Manual, "All about Pepper," (which is to follow that on Tobacco), we shall quote every reference in every local Administration Report to the subject, and woefully poor will be the sum-total presented from that particular source. There is no single Irrigation vote in the list for 1889, we feel sure, which would benefit so many people as the same amount judiciously distributed in the Kanayan districts as "bounties" on the cultivation of certain areas with the pepper vine, in order to revive this important industry.

If we turn to the North of the island, a large extent of this region might be covered with this palm (and perhaps allied species) without special aid from irrigation. At any rate we have the assurance of one of the best authorities in the island that the palmyra grows almost wild if the seed gets covered in decent soil anywhere north of Chilaw, and we have often referred to the Rev. J. Kilner's statement that if every native travelling down the North Road were made to plant one or two palmyra nuts there would speedily be one avenue of palmyra from Jaffna to Anuradhapura. We suppose that if a line were drawn from Chilaw to Trincomalee, a very large proportion of the country north of it could be readily (and eventually with great profit) cultivated with palms peculiarly suited to our drier regions, though of course responding most gratefully to good cultivation and watering. But in place of this most valuable industry extending in the North and East, we are informed that in consequence of the keen demand for palmyra tree rafters, there have probably been more trees cut down in the Jaffna peninsula itself of recent years, than there are young plants put out to take their place.

Without the taste, some training, or at least encouragement from headquarters, it is impossible to expect any change for the better among district revenue officers: they will continue to ring the changes in most cases on "grain revenue" and "irrigation," "ancient ruins" and "village customs." Long ago we pleaded that all cadets for the Ceylon Civil Service should (like the Dutch cadets selected for Java) be sent to an Agricultural College for at least one year's training. This might well be followed by another year's attachment to the local Royal Botanic Gardens. Dr. Trimen could impart invaluable information to future district officers. It may sound an exaggeration, but we venture to assert that Dr. Trimen and his lieutenants in a quite way and with an allowance of revenue money which is quite laughably small, have probably been the means of adding more to the permanent wealth of the island during the last ten years than the whole staff of revenue officers put together with the Governor at their head.

In many other Colonies, we find systems of "bounties" established and worked with most desirable results, and yet nowhere else is there a country or people with better prospects from the extension of really suitable and profitable industries. Ceylon is admirably suited for some of our drier districts. Tobacco gardens could be multiplied very greatly. Pepper should be grown until our export is equal to that of Malabar or 20 million lb. per annum (the Dutch and world's total trade, there is an assured market). Nutmeg, Cassia (which Dr. Trimen has distributed) and a score of other fruit trees, besides the palmyra palm, could be extended profitably. All that is wanted is that the Government and their district officers should "peg away"

by every lawful means at the people in the suitable regions, giving them encouragement and aid and watching over the initiatory steps of new industries as closely and carefully as they now do over the restoration of a tank, dagoba or an ela. To secure the necessary aid and to provide bounties for the first appreciable crops of cotton, say,—surely it is not too much to ask that a “vote for promoting new products” to the extent of Rs50,000 may be included in the next supply Bill. This will be only *one-fourth* the lump sum given without question to “Irrigation.” If in addition an appreciable sum were placed at the disposal of Dr. Trimen we feel sure the Colony and its people would benefit ten times over. A flourishing Government Experimental Garden at every Kachcheri would do wonders for the people.

It will be seen from C. S's letter in next column, that Rangwelletenne estate cannot yet count its nutmeg trees by thousands, though that term, we learn, may be applied to the numerous and flourishing clove trees. There is thus little or no difference so far as our argument is concerned, for the clove tree yielding an abundant crop may prove quite as valuable as the nutmeg; and Mr. Shand's experience shews that with a little care both these spices may be freely grown at a medium elevation, while the nutmeg trees in the Ratnapura resthouse grounds not 100 feet above sea-level, indicate how readily native villagers might be led to grow a few of these very productive trees in their gardens. It is too much, perhaps, to expect a change of policy during the remainder of the present *régime*; but we trust our brethren of the press and public opinion generally, will agree with us that a strong effort must be made to get our next Governor to start a new and different policy in reference to the promotion of agricultural improvement among the natives. We think the Government should be urged to inaugurate three or four Experimental Gardens on a really commensurate scale, under trained assistants from Kew after the pattern of Messrs. Nock and Clark though, of course, without their experience to begin with. Subordinate to these Gardens, District Kachcheries could have smaller ones or at least nurseries under trained native gardeners supplied by Dr. Trimen and there should be every inducement given to the revenue officers to interest themselves in experiments with new products, but more especially in the industries suited to their districts and people. With each annual Administration Report a return should be furnished of the extent to which fresh products had been introduced into the villages, the headmen recording the number of new palm, fruit, or spice trees, pepper vines, cacao plants, or acres of cotton or tobacco added to their villages during the year and the revenue officer giving the totals for his district. This should be done much more easily and accurately than the Blue Book returns now given of existing cultivation. The mere calling for such a return year by year, and the remarks made on it at headquarters would give a new interest to other cultivation than paddy growing. If, in addition, Dr. Trimen and his increased staff were expected to co-operate with the revenue officers and give them their opinion on the villagers' culture of new products, while “bounties” for first crops and prizes at Shows were regularly kept up, certain we are that a new era of lasting prosperity would dawn on the people of the island. In this way, the people, in many districts, would get money for their produce to buy far more rice than they usually consume, and more cheaply than they ever could grow it for themselves. Under our next Governor then, we must urge that the **EXTENSION OF NEW PRODUCTS**

rather than of Paddy-growing should be the chief aim of his Government, while the maintenance of existing industries and irrigation works could of course be provided for. It would not be so much the opening up of so many acres of paddy-fields which would stand to the credit of Sir Arthur Gordon's successor at the end of his six years; but that His Excellency (whoever he may be) had encouraged the planting of so many millions of palmyra palms in the country north of Chilaw and Trincomalee, and so many millions of pepper vines, cacao plants, nutmeg, clove, bread and other fruit trees in the southern half of the island. A Governor who could so report after his term of office would have done more, probably, for the welfare of both Sinhalese and Tamils and the trade of the Colony as a whole, than any ruler we have had since the time of Sir Henry Ward.

NEW PRODUCTS FOR THE NATIVES.

To the Editor, “Ceylon Observer.”

Colombo, Nov. 19th, 1888.

DEAR SIR,—Referring to your editorial on the subject of “Revenue Officers, and the Promotion of Native Industries,” I wish to correct the statement as to the number of nutmeg trees on Rangwelletenne estate. Alas, there are not a dozen. There are, however, a large number of clove trees, some of which are beginning to bear, though as yet sparingly. They grow most luxuriantly, and I think the clove tree is one of the most ornamental in nature.

Though the cost of planting spices in a small way is insignificant, the trouble is considerable, and this, I fancy, is the reason why so little is done in this direction. I quite agree with you that more attention should be given by Government to encourage amongst the natives the cultivation in a small way of such tropical products as Nutmegs, Cloves, Pepper, and Cacao. If the Assistant Government Agents were given the means of raising and distributing plants amongst villagers, the result would soon show itself in considerable exports. In the Western and most parts of the Southern Provinces, the products I have named will all grow, and if only one plant of each was planted in every native garden through the influence of the headmen, the result could not fail to be beneficial, and I am sure the natives would adopt the idea because carrying it out would not involve any cost nor ultimate work.

In the Western Province I know the Assistant Agents are most anxious to foster the cultivation amongst natives of any product likely to be profitable. But the head of our paternal Government keeps a firm grasp on the purse-strings, for everything but magnificent undertakings. The revival of ancient industries appears to be the ruling idea of our Jupiter and his satellites. Modern industries result in perishable gain, the other in undying fame.—C. S.

PRODUCTS FOR CEYLON PLANTERS.—The *Chemist and Druggist* sums up an able review of “Ceylon's Staple Exports” with some words of counsel which the majority of our planters should very carefully consider:—

We should think that the Ceylon planters may find that in future they are more likely to reap profits from the cultivation of a number of comparatively small articles than from a few staples, and among the cultures to which they will probably turn their attention in the first place are cubebs, black pepper, nutmegs, cloves, annatto, vanilla, and other drugs and spices. As the climate of Ceylon is exceptionally suited for the acclimatization of new products, and only a fraction (it is said less than one-ninth) of the island is at present under cultivation, the future of the ancient Taprobane is altogether beyond calculation.

CEYLON UPCOUNTRY PLANTING REPORT :

THE ENTERPRISING MOORMAN AND COFFEE—CACAO RIPENING—A FAMOUS CACAO TREE—GRAND WEATHER FOR TEA.

26th November, 1888.

The enterprising Moorman is out on the prowl at present after coffee. If you have a few bushels of husk to dispose of, or a heap of "tails" or light, you have no end of these insinuating fellows up about, wanting to buy, whose anxiety to relieve you of your produce is hardly in keeping with the tales they tell, of a fall in the price, and a general dulness in the market. They listen to your unvarnished account of things in an attitude bordering between the sceptical and the out-and-out unbelieving; and when you reject their highest bid, and tell them that in coffee at present to wait is likely to win, and that your price is so-and-so, and to that you will hold, they turn their attention to something else—tea, cacao, bark, or even old newspapers,—but they come back to the coffee again as prime favourite. In coffee dealing there is so very much scope for the fine art of manipulation that there is no wonder that the Moorman has a passion for trafficking in it. It has been to the followers of the Prophet an education; and now that coffee is in a state of decline, and the opportunities for trading in it yearly becoming more limited, I expect we shall find that, as a result, the Moorman will become less sharp. There is no other product that I know of that could lend itself so readily to develop the genius of the Moor, and whet him to such a keen edge, as coffee. Tea? it is nowhere in the race; you can't take much liberties there without being found out, and "blacks" and stones would hardly pass. In cinchona there would be a very fine field, except that the analyst is always about as a last appeal. Cacao is all but hopeless—indeed when coffee finally goes there will die with it a wealth of world's wisdom of a kind which has been collected, evolved, and rendered effective in the upbuilding and downfall of several generations of tumbies as they went on trading from year to year. It is melancholy to think that all the dodges which raised the dealing in coffee to be one of the fine arts are now passing away, and will, in time, be forgotten for want of a proper field to exercise in.

The little that remains of coffee on this side has not done so well this year as it did last, and the estimates, which were certainly moderate enough, are likely to be somewhat short. We were terribly stricken with leaf-disease a few months ago, and, although we have now got over that, still I have no doubt that our short crop is partly to be attributed to the bullying of the fungus. Prices however are good, and any kind of trash which has any kind of relationship to good coffee is readily competed for and at good rates. Husk, mostly gathered from the tips of withered branches, is selling at R5 a bushel, which is certainly a fine price. The Moorman who buys your first lot always loses money. I have found this to be invariably the case. You first hear of it through your coolies, who can give you the exact number of rupees the trader has dropped; then your carpenter tells you, and then someone else. It's an old dodge, to choke off intending buyers of any later parcel, and gives a kind of footing for a fresh tussle as to price, when another transaction is being arranged.

Cacao is ripening, and showing a good sample. Some places will do very well, others I know are not so fortunate. Wherever the trees have been highly manured, there as a rule, you have good results. Those who don't cultivate highly have to be content with poor returns, and the longer you have experience of cacao, the stronger will be your

faith in "muck." The trees are not by any means free of pests, and the amount of borers your "poochi"-hunting gang will produce in a day tells of the necessity of constant watchfulness.

A man whose place was not doing remarkably well and who was somewhat cast down in consequence had his spirits wonderfully raised by seeing a cacao tree, said to be *forty years old*, loaded with fruit. He came to the conclusion that all that his estate wanted to change its character for the better, was time, and with that he was comforted.

The weather we are having is grand for tea, and most planters are busy enough. It has been a wonderfully fine year for the high places, but those at medium and low elevations have not fared so well. Although pulling up now, the long-continued dry weather we had through so many months of the year has given us a good deal to make up, which alas! in many cases won't be done. It is pretty clear that a season good for the whole tea zone is a thing pretty nearly impossible. Perhaps it is as well that it should be so, as our tea experts are growing fast enough even under the present sawing of the seasons.—It is like the usual energy of Ceylon men, the efforts that have been lately made to secure good tobacco seed. You hear of seed got from this country and the other: indeed I fancy that there is hardly any place where tobacco has been successfully grown, that indents have not been sent. Every man cherishes his own as most precious. It is clear that the enterprise will not fail for want of push.

PEPPERCORN.

CEYLON TEA FOR THE MILLION.

A SUGGESTION TO SELLERS.

A planter sends us a capital model for a tea-dealer's circular or poster, which we have no doubt will be utilized by many sellers of our teas who will see it in our *Overland Observer*. He writes:—"If I sold tea at home I would have such a bill in large type done for the window, and small bills to wrap up with every pound of tea sold. All honest vendors of Ceylon tea should be supplied with them by the thousand." The suggestion is as follows:—

TEA,

A SUGGESTION.

Is it not a fact that many well-known vendors of tea have built up their enormous trade, and large fortunes, simply by means of their persistent advertisements? Such advertisements stare us in the face in almost every home paper we open; while other notorious means are resorted to in every town in England to induce the people to buy the wretched China congos. Should not our Association take a lesson from this fact, and raise a fund to be expended solely in continuous advertisements? as thus:—

TEA! TEA!! TEA!!!

To the People.

Beware of the TEA you drink! Particularly beware of CHEAP tea. More LIES are told by vendors of tea in their ADVERTISEMENTS, than of any other commodity. CHEAP CHINA TEAS are weak, worthless, and pithy; and would not be drinkable but for the very small quantity of BRITISH-GROWN TEAS generally blended with them.

These ONE or TWO OUNCES in a pound are all the value you get for your money!

Say at one shilling a pound you get 12 oz. of BERT mixed with 4 oz. of British-grown tea!

So that you pay for the real stuff at the rate of 4s pound! at last!

WHEREAS by INSISTING upon being served with GOOD BRITISH-GROWN TEA you can buy the REAL TEA for 2s 6d a lb., unmixed with dirt from China!

How many of your ailments, do you suppose, can be traced to your habit of drinking filthy, low-priced china tea?

HOW TO TELL GOOD TEA FROM BAD.

1. Half a teaspoonful of good tea will make one large cupful, and give a good *second* half-cup.
2. Good tea, when bought, has a smell like a bouquet of sweet flowers.
3. After infusion the leaves should be like a new penny in colour.
4. Each particle put into the pot should turn out the above colour, and be a piece of strong, healthy leaf.
5. Any black bits that go to mud between the finger and thumb are rotten leaves, or dirt, and injurious to health.
6. The liquor when just made should be quite clear and pure.

GET INTO THE HABIT OF TESTING ALL THE TEA YOU DRINK BY THESE RULES.

And (finally) remember that no really good British-grown teas (made by machinery with scrupulous cleanliness, whereas the Chinese prepare their with dirty hands and feet) can be imported under ONE SHILLING a pound, to which sixpence duty has to be added!!

This should be issued by an "Association of British Tea Growers."

CEYLON AT THE MELBOURNE

EXHIBITION :

(By a Lady.)

THE CEYLON TEA KIOSK. OLD FRIENDS TO THE FRONT.
A CAPITAL HINT FOR CEYLON TEA PLANTERS :
PERMANENT CEYLON TEA-ROOMS WANTED IN MELBOURNE.

VICTORIA, Oct. 25th.

I have just returned from a very enjoyable and instructive visit to Melbourne, spent chiefly in the Exhibition, and more particularly in the Ceylon kiosk. The entire Show is now very complete, and much of the 'scattered' impression has disappeared since the exhibits have been arranged. Of course the great amount of space covered prevents a proper idea of the attendance,—in fact, gives at times a feeling of emptiness, but I am glad to say that perhaps nowhere in the building is this less felt than around our well-known motto *Unitas Salus Nostra*.

Before this reaches you, you will have received a copy of the article in the *Age* headed "The Plantations of Ceylon," the shorter notice in the *Argus*, as well as the direct reports from the Kiosk. I had also the pleasure of meeting your friend and correspondent "Old Colonist," whose fluent and graphic pen has doubtless ere now been turned to good account.

As I have from time to time given you a detailed account of the difficulties and progress *re* the P. A. representation here, I feel on this occasion inclined to leave you to gather from "Old Colonist" as an independent witness what is now being done and its probable effect on the Australian tea market. All I need therefore say is, that my most sanguine anticipations are more than realized, and the success already achieved through the small effort made by the Association makes me reiterate my regrets that more was not attempted. For instance, unfortunately for Ceylon, its kiosk is in the vicinity of the elegant marquee into which Van Houten invites all visitors to partake of a cup of his cocoa, and by comparison our tea although prettily is rather shabbily housed.

However tea, not cocoa, is the everyday beverage of Australia, and therefore we console ourselves with the fact that the former product needs less pushing and advertising than the latter. Yet one cannot restrain a sigh for a great opportunity only half taken advantage of, or the abiding regret that the leading spirits of the P. A. should have been so deeply possessed with that safe virtue

"Prudence" as to confine their Melbourne donation to a sum, which to a solitary well-to-do Colonial would be a mere bagatelle in advertizing.

Advertizing full, and without regard to expense is, as you know, the feature of the age, and thus the sooner the localized and therefore timid and unadventurous among our planting mind permits the recognition of this fact, the better will it be for the Ceylon tea industry.

Although rather late in the day as regards the Exhibition, even now much might be done. From remarks in the papers and observations in society, it is evident that families in particular are becoming more and more discontented with the teas supplied to them, and it has been suggested to me by more than one intelligent observer that the P. A. should follow up what they are now doing at the Exhibition, by continuing their support to a tea-room in some central part of fashionable Melbourne.

Supposing for instance that some reliable person undertook to run such rooms for, say, a year, guaranteeing that everything should be done in the best style and under P. A. rules, would it not pay the Association to give some £200 towards rent should the venture fail at first to be self-supporting? I feel certain it would, as, besides meeting a social want, a very considerable business would be done in taking orders as could now be done at the kiosk if the tea stock was larger. As this outlet has, by the way, occurred to the kiosk to assist in its own upkeep, I trust every effort will be made to hurry off a further consignment of tea, and I would again emphasize the necessity for the greatest care being exercised in its selection.

There is a good deal of Ceylon tea in circulation in Melbourne, which is pitiful stuff, and must detract from our good name. Should therefore Tea-rooms be continued to be run after the Exhibition is over, I would suggest that the initial rule be that all teas passing through them either at table or as orders, be specially blended to a standard combining good flavour with fair strength. As the *Argus* remarks, "this Ceylon tea with its delicate flavour is something of a revelation" to tea drinkers, and we should before everything strive to deserve this high recommendation.

Cards of invitation are now being printed, which will be forwarded to prominent residents before "Cup week" (the carnival of entire Australia) and by this means it is hoped to secure further and more influential notice. Considerable interest is evinced in the various exhibits, and the photographs are very good. A number of people have either left cards, or introduced themselves, who have or formerly had connection with Ceylon, and it is proposed to open a Visitors' Book with special reference to such. Were it placed on "Old Colonist's" beautiful round table of many inlaid woods—which he has kindly lent for Exhibition—and surrounded by the "Jubilee Ceylon," "Handbook and Directory," and other Volumes which you are kindly forwarding, we would have the ready-made nucleus of a Ceylon Club! I understand "Old Colonist" had much to do with forming and supporting the Aberdeen Institution which held such pleasant social gatherings some years ago.

I shall have something further to say regarding the effort to popularize Ceylon tea when I return to Melbourne, and I should like to tell you something of the little Seychelles Court with its Vanilla specialities; but I am pressed to catch the mail, and besides, as I have said, would like you to gather your impressions this time from photographs and the remarks of more mature and independent witnesses such as "Old Colonist."

J. J. M.

LATEST NORTH BORNEO NEWS.

(From the *British North Borneo Herald*, Nov. 1st.)

A rare avis in the shape of a white swallow has for the last few weeks been soaring in graceful gyrations round Government House which is regarded by the natives as an infallible omen of approaching prosperity.

Mr. von Donop has procured some carefully selected Tea Seed from Ceylon and any one who may wish to have a few plants can obtain the same by applying to Mr. H. Walker to whose care they have been entrusted. The Lincarbo Pearl Fisheries have commenced and the consequence is an exodus of natives from Sandakan and from the Bay. The fishery shows every sign of being a most profitable one to both Government and the collectors.

A Company is forming in London to buy up an extensive tobacco estate in British Borneo for \$600,000 with the object of exporting the product to the United States.—*The Kansas City Star*, August 20th, 1888. (*Kansas Mo. U. S. A.*)

We regret very much to have to report the death of Mr. Meyners from malarial fever contracted whilst cutting out land for Baron Von Stein's Tobacco Company. Dr. Lamb on a recent visit to Lahad Datu found him in a very precarious condition and brought him back to Sandakan but notwithstanding all that medical skill could do, he passed away on the 14th ultimo. He was buried in the Christian Cemetery, the Rev. Mr. Elton officiating; his funeral being attended by H. E. the Governor and all the European residents. Mr. Meyners was the son of Col. Meyners of Delft, Holland, and a widower at the time of his death and leaves behind him also a son and a brother to mourn his loss.

We have it on good authority that on some of the rivers here stools have been found consisting of over thirty canes and that Mr. Pryer saw one of thirty five canes on the Kinabatangan.—"That is so" said a Dutch gentleman who overheard our informant "but if you tell it to any one in Java he will say you are a liar."

We are glad to learn that Count Geloos has formed a Company in London to take over 26,000 acres in Mamudu Bay under the style of the London Borneo Tobacco Company, Limited, which will start with a working Capital of £80,000 sterling. The 4,000 shares that were offered to the public were more than covered by the applications. The vendor receives no cash and will receive no dividends on the 4,000 shares allotted to him until 20 per cent has been paid on the 8,000 shares allotted to the public; and when 100 per cent has been paid on the 8,000 shares the vendor will be entitled to one fourth of any further profits. Count Geloos' land adjoins Ranow and the terms of sale shew his confidence in the future of the London Borneo Tobacco Company's new Estate.

NETHERLANDS INDIA NEWS.

COOLIES FOR DELI.

Papers laid before the Netherlands States General throw light on the negotiations which have been carried on to turn part of the stream of emigration from India in the direction of Deli. The Netherlands Consul General at Singapore and another official went early this year on a mission to Calcutta for that purpose. They met there, from the authorities concerned every assistance and co-operation in gaining the object in view. The Governor General of Netherlands India has thanked the Viceroy of India in consequence. The Consul General reported that the negotiations had been brought to a satisfactory conclusion.

COOLIES FROM SINGAPORE.

At Batavia, coolies have become scarce. They generally came from Bantam, but this year, owing to the disturbed state of the province, their numbers have been fewer. At last, the supply fell so short that a British firm at that port determined upon importing some three hundred Chinese coolies from Singapore. They arrived and set to work on the 10th October. The Bantam coolies arrived near to the spot, and stood staring with great astonishment at the work of these new competitors. At first there

were fears of disturbances, but the brown labourers took it all very quietly, and did not molest the new-comers at all.—*Straits Times*, Nov. 12th.

[In 1881 estates in the Straits were worked largely by Javanese.—Ed.]

SOUTH WYNAAD.

Crop is extraordinarily late this year; picking can hardly even yet be considered really on, and the coffee is ripening patchily, but I am glad to hear that, so far as can be judged at this early stage, the sample promises to be better than that of last year. The Chermas are in full force and any amount of labor obtainable for weeding purposes. I hear also of sundry fresh blocks of land which have lately found purchasers in this district, which looks as if the belief in the future prosperity of coffee still exists amongst us. There is a great deal of anxiety felt on the subject of crop robberies; and I was delighted to learn that one gang of Punniah had been already captured, red-handed. Though so early in the season more than one estate has been robbed, and it is a known fact that very considerable preparations are being made by the regular "receivers," who are determined that they, at any rate, shall not suffer like most of us from "short crops." It seems extraordinary that such a state of things should exist, and it would be an infinite boon to the hardly tried planters if a more strongly organised system of police could be introduced during the crop season at least. It is the receivers who require severe dealing, for the actual thieves are mere semi-savage slaves, bound to do as they are bid by their far more culpable masters, and yet, so far *nothing* is done for us, and, as often as not, culprits caught in the act escape through means which, in our injured eyes, appear simply inexplicable. Our latest cinchona worry in the appearance of hordes of gigantic grasshoppers, which devour everything, after the manner of locusts. At first they are small, brown, insignificant creatures, which collect by thousands on every tree, and play sad havoc amongst them; after some time these develop into really magnificent insects, beautifully colored, and very large. The next stage is the depositing of countless eggs in the soil around the trees, and what the result of these will be next year, we tremble to anticipate! The weather has, of late, been very extraordinary, quite unlike what we usually expect in October and November, very close and sultry, with constant storms, all of which have been exceedingly trying, and colds, fever and other ailments are the consequent results amongst the coolies. It is "fine growing weather," doubtless, but not suited to drying coffee and bark. Very great quantities of this last product are going down daily to the coast, and it is to be hoped, in our planting interests, that the price will improve.—*Malacca Times*, Nov. 12th.

INDIAN TEA BAZAARS Co., Ltd.

It is proposed to start a company under the above name, with a capital of £25,000 in 25,000 shares of £1 each, the first directors being Messrs. Robert Foote, Tea Merchant, 9 Virginia Street, Glasgow; Andrew Polson, Tea Planter and Importer, 21 Howard Street, Glasgow; and Alexander Wright, Baltic Dyeworks, Glasgow. From the prospectus we quote as follows:—

This Company has been formed for the purpose of acquiring and extending the business at present carried on in Glasgow, Dunfermline, Greenock, Leith, Hull, and other places, under the name of "The Indian Tea Bazaars." The business consists of the sale, wholesale and retail, of all the following:—Teas, Coffees, Cocoa, &c., for household consumption and otherwise, and the sale of these and other necessaries in Box and Lunches in Bantam, especially fitted up for the purpose. The business of the Company is to develop and extend over the whole of Great Britain an opportunity offers. With the growth of the Temperance movement an almost unlimited demand for Tea

* Have grasshopper ever attacked cinchona in Ceylon? — Ed.

Rooms suitable for all classes of the community has sprung up in populous places, and comfortable and attractive places of Refreshment of this description are greatly in request. The success of the Aerated Bread Company of London, the business of which is analogous to that of this Company, and which last year paid a dividend of 22½ per cent, and whose £1 Shares are now quoted at £5 2s 6d, leaves no room for doubt that equal results will attend a similar enterprise in other large centres of population, and next to the Metropolis itself it would be hard to select better fields than those which the Directors propose in the first instance to occupy. Although the business in the Tea-Rooms will be conducted mainly on the same lines as that Company's, the facility for purchasing in bulk exactly the same Tea as is served as Refreshments, will be an additional feature. The demand for Pure Tea for household consumption is everywhere rapidly increasing especially among the poorer classes. By extending the premises taken over, and by starting fresh rooms and shops in localities where openings are known to exist, the Directors hope to bring these "pure and moderately-priced" Teas within reach of the masses at moderate rates, thus conferring upon them an immense benefit, and at the same time developing for the Company a large source of Revenue. "The Indian Tea Bazaars" have appeared to the Directors to be a suitable nucleus for the more extensive undertaking they have in view. The Teas hitherto used in connection with them have been exclusively of Indian and Ceylon growths, which are noted for their purity and high quality; and, although not long established, the twenty-four shops and tea-rooms which are at present in existence are doing an increasing and profitable business. By taking them over as a going concern, the Company will secure the services of a small, but experienced staff, with a qualified Manager and Superintendent; and will thus—while keeping clear of a heavy capital outlay for goodwill, etc.—be enabled to extend its operations immediately, avoid the delays involved in the creation of a new business, and earn profits from the beginning.

A slip enclosed in the prospectus states:—

The present Proprietor of the Indian Tea Bazaars has done more to introduce Ceylon Teas into Glasgow and Scotland generally than almost any man in the Country; in fact, it may safely be said that he has done more than any man in Scotland for the good of Ceylon. The services of a Professional Buyer who has gone largely in for Ceylon and Indian Teas during the last few years, have been promised to the Company, so that there is every prospect of its not only proving a great success financially, but that it will help largely to spread Ceylon and Indian Teas in their pure state.

FARMING IN THE GREAT NORTH-WEST.

To the Editor, "St. James's Budget."

Sir,—As the *St. James's Budget* reaches me in a roundabout way from a friend in British Columbia, I have only just seen the letter in your issue of the 28th of July, headed "Farming in the Great Mackenzie Basin," signed "Robt. J. Rose," and dated from Fort Qu'Appelle, Assiniboia; and in the original of which Mr. Rose forwarded for your inspection the wonderful onion, grown presumably in his garden, the bulb of which you describe as about the size of an ordinary lucifer-match.

It seems to me that, under the guise of friendly advice not to farm in the Mackenzie Basin, Mr. Rose has made a somewhat feeble attack on the district from which he dates his letter. I live, as the crow flies, forty-three miles from Fort Qu'Appelle, and have also had five years' experience of the "droughts," "summer frosts," and "gophers" of which he complains; and though I think I may claim to live in the same "favoured region," I can say that at least my garden produce is somewhat better than his letter would lead intending settlers to expect. Last year I sent twenty-two varieties of vegetables to our local show and did not get even an honourable mention.

The neighbour who won the first prize sent upwards of thirty. At the present moment I have vegetable-marrows, cucumbers, and tomatoes uninjured by frost in my garden; but if I expect a cold night I throw a little hay or an old sack over them. The ordinary vegetables are quite as fine if not finer than those I used to grow in England. A few days ago I cut a head of cauliflower which, when trimmed ready for boiling, weighed 4½ lb. In taking up some English ash-leaf kidneys, I counted on one root eighteen and on another twenty-one potatoes fit for the table. Our main potato crop is not dug yet, but last year the prize bushel of potatoes (60 lb.) contained less than thirty bulbs; or, in other words, averaged over 2 lb. each. Turnips, carrots, beetroot, parsnips—in short, all root crops, are fully equal to the average to be seen at provincial shows in England. I have just pulled up and weighed a cabbage for the table—13 lb. His neighbour, rather larger, I am keeping for our show.

I have no wish to deny that we are troubled by summer frosts, droughts, and gophers. "Grasshoppers" and "beet-pests of vegetable-destroying grubs" I have underton^{ed} escaped: they may be more plentiful in the Qu'Appelle Valley. Nor in this a country in which a man can make a rapid fortune by farming; but I say distinctly that a man can make a fair living by mixed farming—he should not put all his eggs in one basket—and that he can lead a comfortable country life, aided by his farm produce, on an income which would be genteel beggary in England. The "endless ice in winter and millions of every species of mosquito in summer," of which Mr. Rose complains, are no doubt more severely felt in the wide alluvial valley of the Qu'Appelle—especially where, as at Fort Qu'Appelle, the river expands into the "fishing lakes" of many miles in extent—than on the higher grounds. Water attracts the cold and encourages the mosquitoes; but the climate is a most healthy though severe one. The prairie air, both summer and winter, is most invigorating, and 50 degrees below zero is anything but unbearable even by one who, alas! is considerably the wrong side of the half-century. I ought, however, to say that 45 degrees below zero is the lowest I have registered in five years' residence.

Any further information that I can give is very much at the service of your readers, especially of any old officers who in these times of enforced early retirement may think of making a home in a new country.—I am, Sir, your obedient servant.

—PERCY G. B. LAKE,

Lieut.-Colonel late 54th Regiment and 3rd Royal Lancashire Militia.

Grenfell, Assiniboia, N. W. T., Canada, Sept. 11, 1888.

PENANG NEWS.

(Penang Gazette, 26th October.)

AN INQUISITIVE OFFICIAL.

We hear that the District Officer of Nibong Tebal has addressed a circular letter to the Chinese sugar planters in his district, asking the following questions, in accordance, he says, with Section 96 of Ordinance IX of 1887, otherwise the Municipal Ordinance:—

1. Nature of crop and when planted.
2. Area under cultivation.
3. Average yield per acre or orlong.
4. Average price obtained for produce.
5. Cost of manuring and cultivating per orlong.
6. Rate at which land is let if any.
7. Average net profit for last three years.

Another document asking the following still more inquisitorial questions is going round:—

1. Nature of crop.
2. Area under cultivation.
3. Average yield per acre or orlong.
4. Average price obtained for produce.
5. Cultivation expenses.
6. Cost of manure.
7. Cost of manufacturing.
8. Gross annual expenditure past year.

9. Gross annual receipts past year.
10. Commission to manager.
11. Net profit.
12. Value of machinery.
13. Value of premises.
14. Total capital invested in Estate.

Now, while there is no harm in many of these questions, a considerable number are of a distinctly inquisitorial nature. The Government has no power under the Municipal Ordinance, or any other Ordinance, to compel any one to answer them. Comprehensive as the section quoted by the District Officer of Nibong Tebal no doubt is, it certainly cannot be stretched into giving him power to make a man state his income.—*Straits Times*.

SIAM NEWS.

(Siam Gazette, 20th October.)

RICE EXPORT AND PADDY CULTIVATION.

The Rice Export has been:—

Year	Piculs
1877	3,082,507
1878	2,354,547
1879	3,999,654
1880	3,430,040
1881	3,670,773
1882	3,308,995
1883	2,620,950
1884	4,683,360
1885	3,648,615
1886	3,618,497
1887	6,662,620

To arrive at an approximate amount of the whole out-turn of Rice, we must take into account the home consumption of this article. The population of Siam is believed to be from 6 to 7,000,000. If each inhabitant consumes during the year 4 piculs of rice in food or in other form, as cakes, spirits &c., some 24,000,000 piculs ought to be added to the above total to indicate the approximate amount of a yearly crop. We should have then

Year	Piculs
1877	27,082,507
1878	26,354,547
1879	28,999,654
1880	27,430,040
1881	27,670,773
1882	27,808,995
1883	26,620,950
1884	28,683,360
1885	27,648,115
1886	27,618,497
1887	30,652,620

From 1877 till 1883, there was no manifest progress. In 1887 there is an observable increase of 3 millions, and in 1888 an increase of probably 10,000,000 piculs on 1885. Is this increase due to increased cultivation or only to exceptionally good crops? We believe the latter is the case. A surplus of about 10 per cent. on the whole crop can be easily realized by a good harvest; and the three last crops have been exceptionally good. There is no doubt that on the very few new areas that have been cut within the last few years, many new fields have been opened, likewise in the eastern provinces, where high influence plays a rôle in Siam Rice Mills, but we are sorry to notice that in many provinces fields are left idle.—*Straits Times*.

EMANCIPATION AND COFFEE PLANTING IN BRAZIL.—The *Madras Mail* winds up an article on this subject as follows:—"The irresistible conclusion is that, except under the most favourable circumstances, such as short and easy transport, good estates in high cultivation, healthy and pleasant climate etc., European labour cannot be profitably employed in coffee cultivation in Brazil. Every effort is being made by the Government, in combination with the planter, to give immigrant labour a fair trial, and by the close of the present year some 100,000 Italians will be on the plantations, besides men of other nationalities. It seems, however, as if the Brazilian coffee planters are now passing into a condition which will render the survival of all but the fittest among them impossible."

LIQUORICE ROOT.—A report on the trade of Damascus for 1887 states that there has been a remarkable falling off in the export of Licorice root (*Glycyrrhiza glabra*) both in quality, quantity, and value. In 1886 there were 15,944 bales of the value of £10,362 exported; whereas during last year the exportation declined to 3779 bales, of the value of £1492. For the past two years there has been a brisk competition in the trade in this article, which has caused a considerable fall in the price and an overstocking of the market. The demand consequently diminished much during last year, the United States being the only country where the article is in request.—*Gardeners' Chronicle*.

CORSICAN WINE-GROWERS are beginning not only to supply their own market and drive foreign wine away, but also to export in considerable quantities. The export of wine for 1887 was 71,563 gallons over that of 1886, but the import at the same time decreased from 489,953 to 79,562 gallons. The British Consul at Ajaccio, in his last report, says that although the phylloxera has ruined many acres of vineyards, yet it has not caused such ravages as in France, the centre of the island being especially free from the pest. American grafts have been introduced, and in the neighbourhood of Ajaccio many new vineyards have been recently planted. By the last returns it appears that there were about 42,000 acres planted in vineyards, which, taking the average production of 750 gallons to the acre, and allowing for the grapes consumed in the island or exported, would yield about five million gallons of wine.—*Australasian*.

PHYLOXERA IN FRANCE.—The Minister of Agriculture in France states in his report of the wine departments of the country, that flooding the vineyards has been followed with excellent results, and that the reinstating of the vineyards by means of grafting on the American Vines has warranted the experiment. Moreover, the French varieties, when so grafted, gain in earliness, and bear considerably, even in the Medoc district, without loss of fine flavour. After a good deal of research, a method has been discovered by which the vineyard can be restored to fertility in three years. Among other results of grafting, it has been found that varieties of Medoc Grapes can be got to fruit well in the Gironde, where, by direct planting, no good result was attainable. Vines which have been planted in very sandy soil, as on the bank of the Gardon, and in the vicinity of Aigues Mortes, make great progress, and are proof against Phylloxera. We learn that in Medoc sulphur and bi-sulphide of carbon have been successfully employed against the Phylloxera, and the Bordeaux solution (sulphate of copper) against mildew, with similar results.—*Gardeners' Chronicle*.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. III.]

COLOMBO, JANUARY 1ST, 1889.

[No. 7.]

CEYLON TEA AT THE MELBOURNE EXHIBITION.

The mail received today from Melbourne brings accounts of the very annoying and disheartening position in which the Planters' Association seems to have placed their representatives at the Melbourne Exhibition. We call attention to the letter of a correspondent on the subject, and we trust the Chairman and Committee can, at Friday's meeting in Nuwara Eliya, put matters on a proper footing. When it is remembered that Messrs. Hugh and Wm. Mackenzie and indeed other members of the family give their time to the work of the Ceylon Tea Court, free of all cost, not even charging their expenses, to their constituents, it will be felt, we think, that these gentlemen deserve every consideration at the hands of the P. A. and Tea Fund Committee. Indeed, we believe that were it not for the action of Mr. Wm. Mackenzie early last year in urging representation at Melbourne, there would scarcely have been a Tea Fund at all. To bind the hands therefore of the Messrs. Mackenzie in the way now described was surely most injudicious. What can the Committee who sent that Memorandum and Resolution have been thinking about? Surely the planters understand that it is of more importance to Ceylon to win Australia for our tea than it is even to make a stir in America, in Brussels or in Glasgow. Surely too, there is no one so foolish as to suppose that the sale of 5 and 10 lb. packets could interfere with our ordinary export trade? We consider the case so urgent that we trust a telegram will be sent to Mr. Hugh Mackenzie from Nuwara Eliya giving him power to go on with his sales and that another supply of tea is to be at once forwarded. Our increasing export of tea this season to Australia is no doubt, greatly due to the notice taken of it at the Exhibition. The comparative increase may be seen from the following:—

To Australia.	
Oct. 1st to Nov. 29th, 1888 =	214,489 lb.
Do. 1887 =	55,839 lb.

Increase 158,650 lb.

(From a Correspondent.)

MELBOURNE, 13th Nov. 1888.

I wonder if you are aware of the critical position in which the P. A. Tea-house at the Exhibition stands at the present moment.

The instructions to Mr. Hugh Mackenzie were that complete discretion was left him, but he was to try to sell tea in the cup and packet, in the Exhibition, or adjoining grounds; and should he be unable to sell, he was to distribute the tea.

As you are aware, the Commissioners refused to grant him the right to sell in the cup; and nothing can be sold in the Exhibition unless manufactured in it. But shortly after opening the Court, it became clear that a sale of the tea in 5 and 10 lb. packets was possible, and that disappointment would be felt by many, were its sale refused to them. Mr. Mackenzie then wrote to the P. A. telling them so, and asking for a further remittance of tea, as the 1,000 lb. sent would soon be exhausted. To this request the reply is, for a Memorandum of Expenditure, and a copy of a Resolution of the Tea Committee that they could not approve of Mr. Mackenzie's selling tea sent him for *free distribution*,—and this although their instructions were "*sale by cup and packet*, and only failing such,—a free distribution."

Now with the proceeds of the sales effected (say £70) the amount allowed—£6,000—will admit of the Court being kept open till the end of November only. To close it then, would be nothing short of DISASTER.

In the teeth of the facts that the Court is so well patronized; that one hears praise of the tea on all sides; that leading grocers advertise tea similar to that used at the Court; and that orders for Ceylon tea, for this market, are pouring into Colombo in overwhelming numbers,—surely Ceylon planters can see their way to give £50 to £60 to enable their representative to keep the Court open till the end of the year,—even if the arbitrary managers of the Tea Fund should be so blind to their interests, as to decline to guarantee anything further.

It is not claimed that the many orders which have reached Colombo hitherto are due to our exhibits here; but, as a leading broker remarked yesterday, it is incumbent upon us to keep up the demand for our tea. Otherwise, on the arrival of all these large shipments, there may be a glut in the market, and a reaction and disappointment ensue. To help to avert such a catastrophe, don't you think Colombo merchants, who reap commissions on orders, should do something towards helping the Tea Fund? Another £60 from them would enable us to keep open till the end of January, when the Exhibition closes. In any case, the Kiosk and Exhibits will have to be looked after during December and January, as they cannot be removed while the Exhibition is open.

THE PATENT TEA ROLL BREAKER.

Where are tea planting inventions to stop? From our advertising columns today, it will be seen that Mr. Souter of Kotmale has patented a tea roll breaker which ought to come into general use from its moderate price and capital work, saving as it does two men in the factory. We learn that a roll of 300 leaf is thoroughly broken up and separated in 4 to 5 minutes; the same quantity done by hand would take 6 men from fifteen to thirty minutes. The leaf is not torn or broken by the machine. The twist on the leaf is not destroyed by the machine as is often the case when the balls or lumps are rubbed between the hands. The leaf falls in a shower from the breaker and immediately below it. The machine can be attached above a green roll sifter or worked separately. The one at Westhall is working over a sifter. The tea Roll Breaker complete with driving pulley can be obtained for R150, but could easily be made out of old coffee machinery at a trifling cost. We have no doubt that every factory in the country worthy of the name will go in for a tea roll breaker with its better work and absolute economy in labor.

DRUG TRADE REPORT.

LONDON, November 8th.

QUININE IMPORTS IN TURKEY.—In consequence of repeated complaints regarding the alleged fraudulent practices of certain quinine importers in Turkey, who are accused of systematically opening quinine in bottles and adulterating it to a large extent, the Director of Customs in Turkey has ordered his customs officers to place an official band or label over the corks of all quinine bottles examined by them. A charge of about 3d per bottle is made for this.

QUININE FOR THE MILLION.—Mr. Rivers Hicks, who is the gentleman alluded to in the paragraph under this head which appeared in last week's issue, asks us to state that his offer to supply quinine "direct to the consumer" applies only to such places in India and the East as are beyond the reach of ordinary trade influence. In all other places, Mr. Hicks proposes to sell through wholesale firms, and negotiations are now pending for the introduction on a large scale of "penny quinine" through the medium of such firms.

CINCHONA.—At Tuesday's periodical auctions a moderately heavy quantity was offered, consisting of

	Packages	Packages
Ceylon bark	1,935	of which 1,793 were sold
East Indian bark	567	" 525 "
Java bark	49	" 31 "
South American bark	1,284	" 919 "

Total ... 3,835 ... 3,273

It will thus be seen that a far larger proportion of the total quantity offered was sold on this occasion than is usually the case, and this applies specially to South American barks, large parcels of cultivated Calisaya quills and a good many lots of Ouprea bark being readily disposed of. The average quality of the barks shown was decidedly good, more particularly as regards East Indian cinchonas, and in quite a number of parcels sold at prices ranging between 7d and 10d per lb. At first there was a kind of indecision among buyers, and the market proceeded to be a little firmer, and the general result of the sale is a slight advance on the preceding one, the consensus of opinion placing the unit at fully 2d, occasionally reaching 2½d.

The following are the approximate quantities of bark purchased by the different quinine manufacturers and their agents:—

	Lb.
Agents for the Auerbach quinine works	142,979
" Messrs. Böhringer & Sons	133,391
" the American and French works	118,516
" the Brunswick works	79,308
Messrs. Howards & Sons	59,249

Agents for the Jobst & Zimmer works	55,301
Mr. Thos. Whiffen	20,436
Sundry buyers	7,832
Total quantity sold	617,072
Bought in or withdrawn	94,498

Total offered ... 711,570

CEYLON AND EAST INDIAN BARK.—Nearly the whole of these barks were sold, the best price being realised for parcels imported from Madras and Calicut. Ledgeriana chips, rather small, mixed to medium, 2½d to 5d; good to fine bright stem chips 6d to 8d; shavings 5d to 5½d; root, very dusty to fine rich 1d to 10d; renewed, poor to good shavings 5d to 8½d; fine ditto 9d to 11d bold branch chips 1s 1d; original chips 1s; strong, but dusty chips, and good renewed siftings 1s 1d to 1s 2d (in large quantities); one lot of very fine chips 1s 4d per lb.; Succubra, dust 1½d; common branchy to good stem chips 2d to 5½d; shavings ordinary dull to very rich 3d to 1s; root, commons, to good 1d to 4d; fine lots, up to 7d; dull dusty shavings 1s; four cases of medium to bold stout silvery druggists' quill 1s 11d per lb. (the highest price realised in the sales); and ordinary broken quill at 6d to 7d per lb.

JAVA BARK.—The supply was a very poor one, and about 31 cases chips were disposed of at prices ranging from 2½d to 5d per lb. It is pointed out that the direct shipments of Cinchona from Ceylon to the United States have fallen from 554,430 lb. in the season 1885-6 to 392,027 in 1886-7, and 100,980 lb. 1887-8, and the reduction is said to be caused by the stoppage of one of the American quinine works. The falling-off in the exports to some Continental ports, such as Antwerp, Rotterdam, Amsterdam, Bremen, during last year and former seasons, is probably due to the high rates of freights to these places, which were greatly in excess of those to London. But, on the other hand, large quantities of bark passed London in transit only on their way to Germany. The following information concerning "Peruvian bark" is given us in the October Board of Trade returns:—

	1886	1887	1888
October			
Imports	... cwt. 9,700	11,378	9,218
"	... value £ 47,390	47,792	35,261
Exports	... cwt. 11,177	10,556	10,297
"	... value £ 42,558	29,778	24,764
January to October			
Imports	... cwt. 118,796	125,030	120,445
"	... value £ 635,570	585,419	458,560
Exports	... cwt. 91,412	116,012	103,487
"	... value £ 436,133	440,146	284,626

COBES.—Some business is said to have been done at £26 per cwt. for fine quality, but we have reason to believe that that price could be shaded.

QUININE.—There is no alteration in the makers' quotations, but second-hand holders have shown much more willingness to sell this week, and now offer German bulk at 1s 4½d on the spot, and 1s 5d per oz. forward. Transactions have been very small this week. The imports of quinine into the United States, which early in the year showed a great falling-off compared with 1887, have recently been rather heavy. In the period from January 1st to October 23rd they were 1,519,275 oz., against 1,682,886 oz. in the corresponding period of 1887.

NETHERLANDS INDIA NEWS.

EXCHANGES TO THE 17th NOV.
(From the Straits Times, Nov. 26th.)

THE BRITISH BORNEO PROTECTORATE.

The *Java Bode* deems that the British protectorate in North Borneo will prove a benefit to that promising field for industrial and planting enterprise, where so many Netherlanders are now trying their fortunes.

CHINESE COOLIES NOT WANTED.

The Chinese coolies lately imported from Singapore to Batavia for labour purposes have aroused such antagonistic feelings by competing with the native labourer

that collisions between them have been frequent. The Chinese will in consequence be sent back to Singapore.

TOBACCO.

At Rotterdam, recently, parcels of North Borneo and Deli tobacco were put up for sale by auction at the same time. The latter realised prices higher by one-fifth. The brokers expressed the opinion that the Borneo tobacco was too dry and broken in leaf from late planting. They were convinced, from the glossiness and elasticity of the leaf, that should the other shortcomings be remedied, the Borneo tobacco would soon distance the Sumatra article. This is nothing surprising. The soil of East Sumatra has become exhausted. Borneo is only just being opened out.

JAVA SUGAR FOR CHINA.

A little while ago, a Chinaman came to East Java to buy sugar. The consequence is that large quantities of this year's crop have been forwarded to China. It is expected that the export thither will increase still more largely next year. A powerful Chinese syndicate has set to work for that purpose at Surabaya.

THE NEW COTTON SEASON.

Respecting the prospects for the new season, Messrs. Ellison and Co. say:—"Although it does not appear as if consumption will materially exceed that of last season, neither does it appear that there will be any increase in supplies, unless the American crop should turn out to be larger than the current estimate of 7,000,000 bales. On the basis of this estimate the import into Europe may reach 4,670,000 bales. From India it would not at present be safe to reckon upon more than 1,250,000 bales, and it may not reach this figure, as the recent accounts of the crop are unfavourable. Egypt may send 400,000 bales, though there are estimates as low as 370,000 bales, owing to the season being unfavourable for the healthy development of the plant. Last year's Smyrna crop was a failure, owing to drought, but at least 50,000 bales are expected this season. The Brazils, Peru, &c., may send 500,000 bales. (Good authorities think that not more than 400,000 bales will be received; but the South American movements are always very uncertain.) These, with 4,670,000 from America, compare as follows with last season's import and last season's deliveries to consumers:—

	Estimated Import, 1888-89.	Actual Import, 1887-88.	Deliveries to Spinners, 1887-88.
America ...	4,670,000	4,556,000	4,634,000
East India ...	1,250,000	1,120,000	1,308,000
Egyptian ...	400,000	410,000	419,000
Smyrna ...	50,000	21,000	21,000
Brazils and E. I. ...	500,000	504,000	540,000
Total ...	6,870,000	6,678,000	7,030,000
Average weight ...	436 lb.	436-2 lb.	434 lb.
Bales of 400 lb. ...	7,488,000	7,277,000	7,638,000

It will be observed that, though the estimated import is larger than the actual import of the previous season, it is 150,000 bales smaller than the deliveries to spinners. It is obvious, therefore, that prices are not likely to be below the average of last season, unless the American crop materially exceed 7,000,000 to 7,100,000 bales. It is equally clear that an American crop of 7,100,000 bales is wanted to keep up last season's rate of consumption, especially as the stock in Europe is, in proportion to the rate of consumption, the smallest in the history of the trade—140,000 against 812,000 last year, or barely three-eighths of last year's requirements. At the present moment it looks as if the yield would not come out more than 7,000,000; but it is too early yet to hold very confident views on this point, especially as the season is so late that the date of killing frost is more important than usual. Meanwhile we may observe that, though 7,000,000 is the favourite-guess, there are estimates as low as 6,800,000 and as high as 7,300,000."—*Oriental Mail*, Nov. 2nd.

VANILLA.

THE BORDEAUX VANILLA TRADE.

Bordeaux is one of the principal centres of the trade in vanilla, which is imported there to the extent of over 50,000 'b, annually. The exact figures for the last seven years being as follows for that port and for the whole of France:—

	1880	1881	1882	1883
Bordeaux	Kilos. 24,910	Kilos. 23,900	Kilos. 22,700	Kilos. 19,000
France	90,102	72,139	83,594	78,041
		1884	1885	1886
Bordeaux	Kilos. 25,200	Kilos. 22,000	Kilos. 26,100
France	71,877	93,261	120,016

Most of the vanilla now comes from the French colony of Reunion, where the culture is of comparatively recent date, the annual exportation from that island prior to 1845 being only some 6 or 8 kilos, per annum, while during the seven years from 1880 to 1886 the French colonies exported the following quantities:—

	1880	1881	1882	1883
Reunion	Kilos. 74,677	Kilos. 62,047	Kilos. 80,510	Kilos. 90,530
Mayotte	—	—	996	1,100
Tahiti	—	—	350	520
St. Marie, Madagascar	—	—	—	265
Guadeloupe	3,566	5,102	6,166	5,605
Total	78,243	67,149	88,022	98,020

Vanilla is classified in four qualities by the local dealers. The pods of the primeira or first quality are from 7 to 9 in. in length, and proportionally large. They possess in greater duct its value. The chicapuna is less fine; the saecada and abundance the characteristic perfume which gives to the probasura are the smallest. The vanilla vine is at times covered with efflorescence of silvery brilliance, producing a crystallisation similar to that found in the pod, and which is diffuse on the outside of the capsule. This is called vanilla rime, and is in great demand on the Bordeaux market.

There are two different measures in vogue for preparing vanilla for the market. The first consists in harvesting the capsules after they have lost their green tint. Woollen sheets are spread upon the ground, and when thoroughly heated by the sun the pods are spread upon the sheets and exposed to the sun for a certain period. The pods are then put into boxes covered by a cloth, and again exposed to the sun. The fruit should assume a coffee-like odour twelve or fifteen hours after this last exposure. If this colour is not obtained, the vanilla is again submitted to the heat of the sun. This process occupies about two months, at the expiration of which the vanilla is packed in tin boxes containing about fifty pods each, and securely packed.

The second process consists in putting together about a thousand pods and pouring them into boiling water to bleach them, after which they are exposed to the sun for several hours, and then coated with oil or wrapped in cloth cotton to prevent the portions bursting. During the drying the pod avoids sticky liquid, which is expelled in blowing by gentle pressure of the pods two or three times per day. In preparing the capsule for market it loses about one-quarter its original size.—*Scientific and Practical*.

THE TEA WE DO NOT DRINK.

There is hardly any better way of starting a controversy in the daily newspapers in the dull season of the year than that of throwing doubts upon what people should eat, drink, or avoid, and few subjects have so much attractiveness for the free lances in trade disputes as that pertaining to the purely domestic article tea. The discussion on this occasion was opened in the columns of the *Standard* under the sensational heading of "The Tea we Drink," by one who admits himself to be a "Tea Planter," and who "protests against the vile rubbish now being sold in London, and all over the country, as tea." He further says:—"I got a sample from a country town, a short time ago, which the grocer was selling at 1s. per lb., and for which he informed me he gave 4½d. in bond. He then has to pay 6d. per lb. duty, and carriage, possibly another farthing. This leaves him a profit of only 1d. per lb. We thus have this tea sold in Mincing Lane at 4½d. per lb. Out of this the grower has to pay an export duty, in China, of not less than 1½d. per lb., leaving 2½d. to grow the tea, get a profit, pay freight, insurance, warehousing, and other expenses in England and brokers' charges for sale by auction." It will here be seen that "Tea Planter" assumes that this tea came from China, whereas it might have been imported from India, where no "export duty" is levied, and this alone would be the means of adding 1½d. per lb. to the profits of the growers. "Tea Planter" also tells us that he "tried the tea in question, and was astonished that people can be found to drink such stuff. Before infusion it smelt like shoe-leather; after infusion it had a strong flavour of tallow, and the infused leaves had a most unpleasant smell."

The "Planter" goes on to state somewhat needlessly that "his object in writing is to warn people against the vile stuff sold at low prices" (when perhaps his real motive is to invite them to buy some "curious" sort of tea which he has to sell at several pence per pound more), and adds that "the subject is one that requires ventilation." There we agree with him entirely, but not in the sense that other correspondents have written in reply, where they do all they can to throw discredit upon the *bona fides* of firms, wholesale and retail, who seek to supply the public with a beverage which is pure and wholesome at such prices as keen competition and the advantages of free trade enable them to fix. The fact probably is that these disparagers of other men's goods are envious of the success of their neighbours, and think that by injuring others in the eyes of the public they may draw more custom and patronage to their own side, either in the open market or at the secluded shop. The truth is, these writers are for the most part utterly ignorant of their subject, as is proved by the replies which remarks similar to the above extracts have elicited from parties who are equally interested in the trade, and who have a practical knowledge of the question they are called upon to explain. Read first that paragraph of the letter signed "Mincing Lane," which says:—"The merchants (not the wholesale dealers) who import the tea to London have to sell it to the said wholesale dealers at the best price obtainable, and, in the case of the 4½d. tea referred to, the loss to the importer could not have been less than 50 per cent. After deducting the duty in China of, say, 1½d. per pound, the native would then have something over 7d. for his produce, and not 2½d., as stated—a price amply sufficient to enable him to make fair quality. Doubtless, some very common stuff does leak into this country, but to speak of the teas the grocers are now selling, duty paid, at 1s. per lb. as "vile rubbish" is absurd. In corroboration of this view "Expert," another controversialist, informs us that "Tea Planter" can know little, if anything, of the Mincing Lane market. The mere cost of tea in China, the import duty, and the various other charges, have absolutely nothing whatever to do with the price of tea in this country. This is regulated by the public auction sales in the

Commercial Sale-rooms, which are unreserved, so that the teas just fetch what buyers consider them worth, in open competition. It is absolutely untrue that 'leaves once used are dried and rolled, mixed with a little fresh leaf.' It would never pay in this country, and could not be done without almost instant detection. If done in China (as it was many years ago) it would be rejected by the officers in connection with the Customs, and condemned."

Our daily contemporary who has been publishing these random effusions has also been led to indulge in some imprudent comments in a special editorial on the subject, mentioning that "the beverage with which hardened tea-drinkers like Dr. Johnson, 'amused the evening, solaced the midnight, and welcomed the morning,' was not quite the herb in which so many of his country-folk find a moderate degree of comfort. At 8s or 9s. the pound it was reasonably pure, and, though lacking something in nicety of preparation, was better than the hastily-oured stuff which is despatched to meet the demand for 'a sound family tea' at 1s. 3d. the pound. The adulteration came later." This, a correspondent signing himself Archibald Weir, absolutely denies when he declares that, according to a notebook of his, the foregoing "remarks on the purity of tea in Dr. Johnson's time are slightly optimistic. In 1777 an Act was required to prohibit counterfeiting tea with sole, liquorice, ash, or elder leaves, by imposing a penalty at £5 for every pound sold or found in possession."

From this extreme of running down the teas of the present day, as deleterious, poisonous, and no one knows what, the same daily print has the inconsistency to rush to the opposite one, by stating that, "Accustomed to the low-priced article which the cutting competition in Mincing Lane has put before us, few men think or know that there exist, even in China, growths worth 40s. or 50s. the pound, and that in the famous district of Uji, in Japan, there are some valued at more than 60s. the pound. Of course, we may well believe that there is not a great deal of this 'chop' in the Yokohama market. However, 10s., 12s., and even 15s. is by no means an uncommon retail price in Moscow and St. Petersburg; and in London, brands quite as high, and as well worth the money, may be obtained, though, perhaps, not in the shops which profess to sell Fowery Pekoe at 1s. 4d. the pound." Much more of this hyperbole would take away our breath, and we are glad to quote the rejoinder of "Mincing Lane," whose letter has been already alluded to, that "The highest price paid for black tea in China this last year was about 60 taels per picul, or rather over, say 2s. 4d. per lb. in bond; and never have I heard of such a price anywhere approaching the equivalent of 40s. to 50s."

Exaggeration and misrepresentation mark the greater portion of the recent correspondence on what they term the "Tea we Drink," showing that all they urge is not prompted by a desire to enlighten the public consumers of tea, so much as it is to benefit, enrich, and advertise themselves and their connections; and as the existing state of things in the trade is the natural outcome of generations of experience, competition, and enterprise in every form, we would fain believe that it will not be this class of grumblers who will introduce a new system of business that will make tea-drinking a more innocent and cheap form of indulgence than it is now. The dealers, both wholesale and retail as well as consumers, will therefore give little heed to what they see in the daily papers concerning tea, as there are few authorities on the subject who are to be trusted, not from any dishonest motives on their part—far from it,—but simply because they cannot always look at purely trade questions in an impartial light; and for this reason we ask our readers to adopt the idea, that what these busybodies have been talking about is not the tea we drink, but, for our credit's sake, "the tea we do not drink.—The Grocer.

OUR BREAKFAST-TABLE AND ITS ADULTERATIONS.*

By A. W. STOKES, F.O.S., F.I.C., Public Analyst to

Paddington, Bethnal Green, and St. Luke's.

Tea next engaged the attention of the audience. Its method of growth and preparation were illustrated by some beautiful Chinese paintings made on rice paper by native artists. The properties of its constituents, including the alkaloid theine (found also in coffee, and known there as caffeine), were enlarged upon. Mr. Stokes pointed out the facing of the green leaves, to give them a better appearance, with Prussian blue and silicate of magnesia, and the microscopical method of detecting this. The characters of foreign leaves and of exhausted tea leaves, as well as those of "Lil tea" (containing iron-sand) were described. Experiments to detect the presence of tannin or of iron were performed. Incidentally it was noticed that tea in the seventeenth century was sold in England for from 5*l.* to 10*l.* per lb., and that Parliament levied a duty of 1*s.* 6*d.* per gallon upon its infusion, which tax was afterwards changed to a duty of 5*s.* per lb. upon the dry tea. No regret was expressed at the failure to obtain a demand for the compound of tea and spirits known as "Robur" brought out a few years ago. Tea-making and tea-tasting were noticed. One tea-taster said that in the late busy tea season he had tasted as many as 530 samples in one day.

In regard to Coffee its constitution was referred to, as well as its growth and preparation. It has a variety of adulterants, such as chicory, dates, figs, acorns, roots of dandelion, turnip, wurzel, &c., all of these being first roasted and then ground. Chicory is, however, the most frequently found adulterant; samples advertised as "French coffee, prepared by a patent process, whereby the aroma, &c., are preserved," are usually heavily adulterated, the "patent process" being the addition of 60 to 70 per cent. of chicory. The lecturer described how a customer might be deceived even when he saw his coffee ground in the shop before his own eyes, either by some chicory being already in the mill or by chicory moulded into the shape of coffee-berries being mixed with the unground coffee. The simple test of coffee floating on and not colouring water, while chicory sank in the water and coloured it, was exhibited, and the scientific methods of discovering the amounts of the various adulterations were duly expatiated on.

Cocoa, as the only really nourishing beverage, except milk, met with a description of its source and preparation. It was shown to contain half its weight of a peculiar fat of high melting-point, known as cocoa-butter. This fat is very useful because, unlike other fats, it does not get rancid on keeping. It is largely used as a constituent of the cream of chocolate-creams, for pessaries and for pharmaceutical preparations. Like tea and coffee, cocoa possesses an alkaloid (theobromine), similarly, too, it contains a quantity of a tannin compound. Strange to say, almost all of the favourite beverages taken to by men are of an astringent (tannin-containing) character. The large proportion of fat present in cocoa prevents its use by many people; hence samples from which most of the fat has been extracted, find a ready sale. In other cases not only is most of the fat taken away, but arrowroot or sago and sugar are added in large quantity. Such samples form a pasty mass when boiled with water, in fact "thicken in the cup." They are frequently known as homoeopathic cocoa, and some of them possess so little cocoa as to form merely a species of gruel. Luckily, the microscope, the proportions of fat and of phosphates are means whereby the adulterations can be estimated.—*Continued in*
Druggist.

* Abstract of lecture given November 8, 1888, to the Chemists' Assistants' Association.

TOBACCO PLANTING IN BORNEO.

From various widely-scattered sources, we have recently culled and published a number of facts bearing on tobacco-planting in Borneo; and the announcement of a British protectorate over a large portion of that country affords a convenient opportunity for considering the subject as a whole. The decadence of Deli appears to be merely a question of time. The price of that famous tobacco is falling not on account of over-production, but because the quality of the product is deteriorating, the result of the cultivation of inferior soils. For fine leaf the demand is keener than ever, and the prospects of North Borneo plantations may be said to hinge on the quality of the tobacco they may produce; if it can be employed for "coverings," these estates will soon be placed in a very enviable position. There is of course no longer any doubt that tobacco will grow in North Borneo, and the question of quality seems to be in a fair way to be definitely settled. A Dutch contemporary says of Borneo tobacco: "It is used as coverings for cigars, the large size, and extreme softness and silkiness of the leaf admirably fitting it for this purpose." This favourable opinion of Borneo leaf has been confirmed by a number of experts. As a matter of fact, the last sale of Borneo tobacco in Holland was that of the crop grown on the Ranow Estate by the Count de Geleoe. This shipment realised fl.1.26, or less than was expected by some; but if we are rightly informed a serious accident happened to the drying sheds while full of tobacco, and the quality suffered greatly in consequence. Still fl.1.26 is a very good and remunerative rate; and the managers of many Deli estates would be well pleased if their crops would sell at the same price.

With one exception, the plantations are all the property of foreigners, the majority of these being Dutchmen, who find that British Borneo offers them greater inducements than either Sumatra or Java. Indeed North Borneo is "British" more in name than in substance, the only purely English establishment in the country worth mentioning being the Planting and Trading Company. Even in the shipping trade, which we are apt to look upon as being peculiarly our own, the foreign element enters largely in the competing steamship lines. So far as tobacco planting is concerned, this is hardly to be regretted, and it is very encouraging to find experienced planters leaving Deli and Java for North Borneo. They know thoroughly well what they are about, and are the best judges of soil, climate, and the other conditions relating to the successful cultivation of tobacco. The present keen demand for land, however, has naturally resulted in a certain number of "jobs" being put through by persons who take out provisional leases which, as a general rule, are promptly dubbed concessions. The concessions are then sold at a profit, before the land is selected or surveyed, or a stroke of work done upon it. This easy way of making money is profitable solely to those to whom "lease" and "concession" are convertible terms, and is not of much benefit to the country in which they operate. Land which is actually known to exist, and upon which some measure of work has been done, certainly offers the greatest degree of security to intending investors. It must be remembered by the general public that all land is not tobacco land, and that it is as easy to start "Wild-out" tobacco companies as mining ventures of the same breed. Of course, it is a matter of notoriety that many of the Dutch estates have paid dividends of over 100 per cent. per annum for several years running, and such is the case. Borneo tobacco companies appear to offer a fair opportunity for men who are obliged to take the considerable risk which necessarily attends all forms of planting.

The general conditions of tobacco planting in North Borneo are undoubtedly excellent. The Government of the country, though a little weak and inefficient in many ways, adopts a liberal and wise policy in respect

to this particular industry. But it is to be hoped that even the present administration may be improved and reformed in many notable ways if the new British Protectorate is to exercise any good and useful influence, and then all should go well. Even at present the way of tobacco planters in North Borneo is made smooth for them by the Government. Steam communication also is cheap and frequent, there are no native rajahs or petty chiefs to bother about, and there is a total absence of fire-raising Battaks and many other objectionable elements which have made themselves felt in Sumatra. In these circumstances it seems probable that tobacco planting in Borneo has a good future before it.—*Straits Times*, Nov. 7.

BUYERS OF HIGH AND LOW CLASS CINCHONA.

In our issue of October 27 there appeared a letter from Messrs. Zimmer & Co., of Frankfort-on-Maine, the quinine manufacturers, drawing attention to what they consider a source of possible injustice in our market reports, viz. the enumeration of the approximate weight of bark bought at the London auctions by the various manufacturers or their agents, without the collateral mention of the quantity of quinine sulphate represented by that bark. Messrs. Zimmer & Co. made out a very fair case for grievance, especially as concerns their own firm, by pointing out that, whereas they are in the habit of purchasing bark averaging 4 to 5½ per cent. quinine sulphate, other factories usually buy much poorer cinchona, and that therefore the mention of the bulk alone may convey an unjust idea regarding the producing capacities of different factories. We have no hesitation in saying that we fully appreciate the force of our correspondents' remarks, but we cannot quite see how it would be possible to overcome the difficulty to which they allude under the system of private analysis now obtaining in London. Attention has been repeatedly called in these columns to the superiority of the system prevailing at the Amsterdam bark auctions, where the analysis of each lot is printed in the catalogue, thus affording to all a safe guide to the market. This system was introduced in Amsterdam by the Netherlands Trading Company, and it has since been adopted by all the other importers, which alone is strong evidence of its soundness, though for advocating the adoption of this plan by the London importers we have been foolishly abused and accused of a desire to play into the hands of our Dutch rivals. In time, perhaps, the guiding spirits of the London market may take a leaf out of the Dutch book; but meanwhile it would scarcely be feasible for anyone not a large buyer to analyse every lot advertised for sale, and the only moderately reliable clue to arrive at the standard of the bark sold at the auctions would be to compare the prices realised with what is generally said to be the average unit—a rather time-robbing process to apply to an auction of about 3,000 packages. But with a view to remedy as far as possible any injustice which may have been done to some buyers by our reports, we have prepared a table showing the number of packages and the relative percentage proportions of high and low standard barks bought, so far as we could ascertain, by the quinine manufacturers at the last three public auctions. Taking first the high-class barks, selling at 8*l.* per lb. or higher, and presumably equalling, therefore, from about 4 to 7 per cent. quinine sulphate, we obtain the following results:—

November 6 October 23 October 9

	Pkgs. P. c.	Pkgs. P. c.	Pkgs. P. c.
American and French	467 46	139 45	173 34
Zimmer & Co. ...	140 11	57 19	29 6
Böhringer & Sons ...	156 15	64 20	159 32
Howards & Sons ...	205 20	2 1	119 24
Brunswick Works ...	31 3	45 15	20 4
Auerbach Works ...	2 —	— —	— —
Thos. Whiffen ...	17 2	— —	3 —

This table shows that, in the last three auctions, the principal buyers of high-class barks were the agents for the French and American quinine makers, Messrs. Howards & Sons, Zimmer & Co. and Böhringer & Sons, while little or no high-priced bark was bought by the Auerbach and Brunswick factories. Next, treating in the same manner the distribution of low-class barks selling at 2*l.* per lb. or less, and therefore probably containing only about 1 per cent. of quinine, we arrive at the following figures:—

November 6 October 23 October 9

Pkgs. P. c. Pkgs. P. c. Pkgs. P. c.

American and French	8 5	— —	— —
Zimmer & Co. ...	8 5	27 21	— —
Böhringer & Sons ...	— —	4 3	13 15
Howards & Sons ...	4 2	10 8	13 15
Brunswick Works ...	121 71	2 2	12 15
Auerbach Works ...	26 15	83 66	47 55
Thos. Whiffen ...	4 2	— —	— —

From this table it appears that the Auerbach and Brunswick factories took the bulk of low grade cinchonas at the last three auctions, though it must be added that Messrs. Zimmer & Co. themselves purchased a fair share of these on October 23. It is right to point out, however, that we do not claim for our figures more than an approximate exactness. The buyers at the sales, with one or two exceptions, always bid in an undertone or by nodding of the head, and it would sometimes puzzle the most experienced frequenter of the auctions to indicate definitely the allottee of certain lots. Again, in the course of a year or so the proportions may conceivably vary considerably for those given by three auctions only. Bark is sometimes purchased privately between the auctions, and we need scarcely say that so far as the quality of the product is concerned, the standard of the cinchona is no criterion at all. And in justice to factories which may appear small purchasers it should be stated that they are so only because they decline to follow the policy of what are termed the speculative manufacturers, and that, if more remunerative prices should prevail, they will doubtless again be found to purchase a proportion more in accordance with the undoubted importance of their works.—*Chemist and Druggist*.

BOTANICAL GARDENS AND PARKS IN BANGALORE.

Visitors to the Lal-Bagh at Bangalore do not require to be told how successfully these Gardens have been managed by their present Superintendent, Mr. Cameron, still there are many experiments being carried on and much valuable work being done which do not meet the eye of the ordinary visitor. Of these however, the report for last year, which has just been issued, contains full details. The year 1887-88 was, on the whole, a favourable one. The rainfall of 35 inches was fairly distributed over the months from May to December, though apparently there was no rainfall during the other four months. In the former months there was rain on 68 days, and only in October was the fall at all excessive. In the month nearly 11 inches of rain fell, which did considerable damage to the early ragi crops, and the rain was closely followed by myriads of insect larvæ, which committed great havoc among fruit trees, grass, and pulse crops. Specimens of these larvæ were sent to the Indian Museum, and reported on by Messrs. Wood Mason, and E. C. Cotes. One of the most destructive was the larva of *Pyrales* Sp. a small caterpillar which, in its brief visit of only ten days, "attacked the lawns, and literally ate up every green blade of grass," so that the lawn in the centre of the Gardens, which is regularly mown, "looked for a few days as if a fire had passed over it." Mr. Cotes recommends the use of weak emulsions of kerosine oil and soap or milk, compounds of arsenic, for dealing with this pest. Another very destructive class of larvæ chiefly

attacked the soare crops. Mr. Cotes believes it to be the larvæ of two allied species of noctues moths, one of which was much like *Heliothes Armigera*. This is a cosmopolitan pest, and an omnivorous feeder. It has infested dhal in Dehra Dun, and is well known in America, where it has been attacked with some success with kerosine and arsenic.

Turning now to the records of the experimental cultivation, we find the results full of interest. Potato disease has been spreading to an alarming extent during the last two years, and it is recognised that something must be done to save this valuable esculent, which is now considered an essential part of a European's diet here as it is at home. Much can be done to mitigate the severity of the disease by choice of suitable soil and manures, but, generally, the most effective plan is to obtain new varieties. Seventeen new varieties were experimented on during the year, and though it is as yet too soon to form an opinion of the relative merits of these, the results have been generally good, and the Superintendent is confident that he has now good material to work upon. The local gardeners are not slow to recognise the advantage of having improved seed tubers, and during the present year the cultivation of these is likely to pass beyond the experimental stage. Amongst the new food plants introduced the most important is the Chocho whose fruit and yam-like roots are largely used in tropical America for food. Three ripe fruits of this plant were obtained from the Superintendent of the Haakala Gardens in Ceylon, and in three and a half months after their receipt Mr. Cameron had plants laden with fine fruits. These were freely distributed to local gardeners, and the plant being a perennial one of easy growth, may be considered to be fairly established in Bangalore. Well grown fruits should weigh about 3½ lb. each. "In consistency and flavour they differ slightly from custard marrow." Experiments have also been continued on the tree tomato, which has fruited several times, and on the "Paragon" tomato from Philadelphia, which "promises to surpass the finest of its kind." A large number of fruit trees were received from England during the year, most of which are to be planted in the Palace Gardens, where everything is favourable to health, growth and rapid propagation. The experimental cultivation of the Arabian date palm begun in 1885, has been continued. These experiments are on a tolerably large scale, for 690 offsets and 163½ lb. of seed have from time to time been obtained and there are now in the nursery 1,351 date palms. Those which were planted out in the grounds in October 1886 have grown very satisfactorily, and the largest of them are now six feet high, with a leaf diameter of from 5 to 6 feet. In their early years the date offsets require to be carefully preserved from the attacks of white ants, which are attracted by the dead fibrous matter on the stems and leaf scapes, but after a time they are free from danger from this source. A number of rooted offsets which were planted out at Hebbal, on the banks of a nullah, have not been a success, and this confirms the results obtained in other parts of the Presidency as to the necessity of selecting suitable soil, free from excessive moisture for these plants. Instead of an indiscriminate distribution of the plants over the country, Mr. Cameron proposes to form a local plantation under shaded surroundings in a suitable locality, whence, as the case of the fig plants, offsets and seeds could be distributed with more greater hope of success.

The Hebbal plantation continues to make progress, and a new estate of 18 acres, of which over 2,000 are now under cultivation, planted with the "Paragon" tomato, and with American grapes, was this year taken up by His Highness. With a view to the introduction of the tree tomato, Mr. Cameron has been to the United States, and will be returning to Bangalore in July. The cultivation of the tree tomato has been greatly curtailed by the receipt of a large Burmese credit from Mr. J. H. Gilbert, Principal of

the Rangoon College. Of these Mr. Cameron writes that they form "the most valuable gift the gardens have received during my term of office." The net cost of the Gardens to Government was Rs13,728.

Of the other Parks and Gardens under Mr. Cameron's charge not much need be said. All who know the Cubbon Park will be surprised to learn that it is kept in its present admirable order for an expenditure of only Rs1,316—a sum which does not leave much margin for improvements of any kind. The Palace Park and Gardens are also under Mr. Cameron's care. Fortunate on the whole as to soil and situation they have developed rapidly, and now form one of the sights of Bangalore, and as remarked in the report, "When the Palace is completed, His Highness the Maharajah will have a mansion and grounds that are not equalled in Southern India." Much has been done in the way of planting trees and laying out flower beds, but a good deal of planting has still to be done in the rear of the Palace before the work can be held to be complete. The fernery, which now measures 127 feet by 27, is the largest of its kind in Bangalore, and contains a wonderful collection of beautiful plants. An appendix to the report contains a list of 617 plants collected in the Bangalore district with their technical and their vernacular names, the latter being given in both English and Canarese. This list has been drawn up with the assistance of Mr. M. A. Lawson, and forms the first part of a systematic list of the plants of Mysore with their authentic vernacular names—a work of much practical value.—*Madras Mail*.

THE MATERIA MEDICA OF CEYLON.

Pharmacy in the East was in ancient times practised by the priesthood, and this was the case long before any system of a materia medica was reduced to writing. Ceylon possesses what is believed to be the oldest work on pharmacy in the east; it was compiled by one of the ancient sovereigns of that country a century or two before the Christian era, and at the present time it continues to be consulted by village practitioners, who are, however, in most instances incapable of distinguishing between what is useful in its contents and what is simply worthless. Its royal author, who found time to study the medicinal properties of indigenous roots, herbs, and gums, not only acquired a practical knowledge of all these things, but applied that knowledge personally in hospitals and dispensaries erected by him at considerable cost in his capital. In the suburbs of that ancient city there were formed botanic gardens in which the most useful herbs and plants were grown for hospital use. In the record of the materia medica of that day prepared by the sovereign of Ceylon there were many articles named not known at the present time, whilst a good number of those mentioned in it are known to be of very questionable value; but neither is there any doubt that this "King's book" made reference to plants and drugs the use of which has in the present day been adopted not only by the ignorant village practitioners of Ceylon with the greatest advantage, but by European members of the profession in the treatment of diseases prevalent in that country.

The native practitioners, who continue to practise on the old lines of the medicine, being employed powerful or harmful remedial agents, being content to rely on the palliative uses of emetics and purgatives, assisted by an extremely low diet, so that, whilst often failing to effect a cure, they rarely cause mischief. Better methods have been introduced from Europe, but the ignorant natives are not slow to apply the principles of the former to the treatment of the latter, and the country by means of sending for the most powerful and best, without any regard to the quality of the medicine, by the use of which the natives are enabled to cure many of their ailments, and to give relief to the suffering, and to supply the deficiencies of the pharmacopœias of Western nations.

In the native materia medica, as recorded in their books, there are a large number of plants declared

to be remedies for snake-bites, but experiments carefully and repeatedly made by European practitioners have demonstrated the worthlessness of these supposed remedies; and an experienced local medical writer on this subject has declared that no antidote for the poison of snakes has yet been found in the vegetable kingdom, though it is not improbable that in the natural order of Aristolochiaceæ such may be discovered.

The Ceylon Court of the Colonial and Indian Exhibition in 1883 contained a collection of nearly four hundred drugs indigenous to that island, found chiefly in the hill districts, but not nearly representing the entire materia medica of the island. They had been collected by Dr. Trimen, Director of the Royal Botanic Gardens at Kandy, who described them in a catalogue from information furnished by native village *vederales*. In the descriptive catalogue of that court the compiler felt bound to admit that the uses of these remedies must not be supposed to be based on any real properties in a large number of cases; much is traditional, in the same way as, in the middle ages and up to the seventeenth century in Europe, numerous plants which are known to be quite inert were credited with virtues on the authority of older writers and astrologers.

Amongst the medicinal products of Ceylon the "BELI" or "BAEL FRUIT" (*Ægle marmelos*), well known in this country as a remedy in cases of diarrhœa or dysentery, especially when the attack is accompanied by fever; but native medical books and *vederales* attribute to the root, leaves, and bark of the bael tree qualities as febrifuges to which they are certainly not entitled. It is the practice with many practitioners in Ceylon to boil the unripe fruit, and afterwards bake it under hot wood ashes; others employ the soft pulp of the ripe fruit in its natural state. When it is intended to be kept in store for any time, or exported, the fruit is gathered before being fully ripened, cut in to thin slices, and dried thoroughly in the sun before being packed for removal. As this tree grows readily in almost any soil in high or low districts, and needs no kind of cultivation, it might be propagated to any extent with a view to a larger trade in the dried fruit.

"KOTHOMBA BARK" (*Azadirachta indica*).—The bark of a tree common in the maritime districts of the island, employed in the form of infusion with much success as a febrifuge, the patient being at the same time kept on extremely low diet, almost to starvation-point. The fruit of the tree is said to possess purgative properties, whilst an oil made from the seeds is applied externally in cases of rheumatism. In rheumatic affections the bark of the "KAHATA" (*Careya arborea*) and of the "DAMA" tree (*Calophyllum inophyllum*) are both employed with some success in infusion.

In cases of diabetes an infusion of the leaves of the "Ranacondra" (*Cassia auriculata*) is employed very generally, and with good results. It is extremely useful in allaying the parching thirst which invariably accompanies the disease.

The woody stem of the "WENI-WEL" (*Coscinium fenestratum*), infused, forms an excellent tonic and febrifuge, and well dried in the sun has been exported to Europe. It has also been found to possess considerable antiseptic properties—meat steeped in the infusion keeping perfectly fresh for several weeks. A strong infusion is employed by native mat-makers for dyeing their wares a bright yellow.

The "ATANA" (*Datura fastuosa*) is a species of thorn-apple, possessing in its leaves and seeds therapeutic properties similar to those of belladonna, and which are contained in the active principle, *datuwin*. The dried leaves are rolled into the form of cigars, and in cases of asthma smoked with good effect. It is a very common plant in most of the districts in the interior, where it thrives in thin, poor soil, and might, therefore, be extensively grown.

The "NIYANGALA" (*Gloriosa superba*), a very poisonous plant, and known as such from olden times, being mentioned in the most ancient work on medical subjects, is a wild, quick-growing climbing plant, having

a pretty variegated flower; all parts of it—root, leaves, and seeds—are equally poisonous. It is employed by Singhalese women to procure abortion, and also for suicidal purposes.

The "IRAMUON" (*Hemidesmus indicus*), or Indian sarsaparilla, a freely-growing creeping-plant, is indigenous to the low country of Ceylon, where it is found very plentifully in all light soils remote from cultivation. Its long tenacious root and stem have an aromatic and slightly bitter taste, alterative, diuretic, and diaphoretic. A decoction of the root is prescribed with decided success in syphilis, rheumatism, and diseases of the blood. The plant might be collected and dried for export in considerable quantities.

The "GAMMAHE" or Ceylon Kino tree (*Pterocarpus Marsupium*) yields gum kino from its soft fleshy bark in fair quantity. The tree grows freely in the poorest soil, and might be very extensively propagated by the village population, and a considerable trade in the article created at a low rate.

The "SAMADORA" (*Samadora indica*).—The wood of this tree is an excellent substitute for quassia; an analysis has shown that it contains more of the active principle *quassin* than the ordinary quassia of the drug market. It can be grown in any description of soil.

"GODA-KADURA" (*Strychnos nux-vomica*).—The nux-vomica plant of Ceylon is a free grower and capable of being largely propagated. A sample of the seed examined by Prof. Dunstan yielded 1.14 per cent. of *strychnine* and 2.60 *brucine*. The plant is very abundant in Ceylon, and at present only one or two small shipments have been made to Europe. Analyses of the seed more recently made show the proportion of *strychnine* to range from 1.15 to 1.78, and of *brucine* from 2.86 to 3.63.

That a considerable drug export might be made from Ceylon to Europe with advantage is beyond doubt, and as all the medicinal products mentioned above grow abundantly, without any attempt at cultivation, in districts where native population exists largely, they could be collected, prepared, and shipped at a moderate cost. The product of the cinchona tree, now so largely exported from Ceylon, has not been included in the above list, it not being indigenous to the island, but introduced and cultivated almost exclusively by European planters.—*Chemist and Druggist*.

TEA BOXES.—The *Englishman* propounds the following conundrum:—Why does Assam not make its own tea boxes? The tea boxes are imported in great numbers from Burma, and though the boxes cost more than the locally made articles, the tea sent in them to England sells for a better price, as there is a good demand for the empty boxes.—*M. Mail*.

SUGAR AND COFFEE IN JAVA.—Much is said in Java about the European sugar convention. The most general opinion seems to be that it can only lead to disappointment to expect any good results from the suppression of all premiums on sugar, and that the only way in which Java can head the concurrence of other sugar producing countries for the future will be only found in reducing the cost price of the Java Sugar as much as possible by improvements in the machinery, cheap labour, &c. The trial plantations in the Residency Cheribon with Sugar-cane bibit from Borneo are reported to be a total failure. The expenses came to thousand guilders per bouw. Great dissatisfaction has lately been shown with the natives at the Government persistency in keeping Java Coffee culture in its own hands and not giving it up to private industry. As the Coffee culture forms at present one of the principal sources of income from its Colonies to the Dutch Government, and as the Colonial estimates for next year, now before Parliament, close with a deficit of eight to nine million guilders, it is not likely that they will do anything of the kind, at least for the present, but according to general opinion, they will have to raise the payment to the natives for their labour in several districts at least or expect in a few years the total ruin of the Government coffee gardens.—*Singapore Free Press*.

LETTERS FROM JAMAICA:—No. 26.

A WET YEAR IN JAMAICA—GOOD COFFEE CROPS AND PRICES—THE FUTURE OF COFFEE—CEYLON RESIDENTS IN JAMAICA—JAMAICA AFFAIRS.

Blue Mountain District,

For packet of 13th October 1888.

Paucity of materials must be my excuse for not having addressed you for the last three months, and even at present I shall find it difficult to find sufficient materials to fill my customary letter.

From what I read in the *Ceylon Overland Observer*, our weather here seems to have been similar to yours in Ceylon: dry till the middle of April, then very heavy rains which did a great deal of damage by landslips, and which, on your railway, seem to have caused several heavy "breakaways" as we call them here. We have also experienced a wet August and September, and should our usual October "season" be severe, shall have had more rain than enough. Oh that we had a cart-road and a set of mills in Kingston there to get our coffee cured Colombo fashion. As to crop in the Blue Mountains proper, owners have about realized expectations; one estate, *Radnor*, did wonderfully well, but with this exception there was no approach to a "bumper," and what is curious, all the high estates have still coffee on the top fields,—a sort of autumn crop, which is not the usual custom in Jamaica, crops being usually considered over by the 1st of August. As to prices we have had no cause to complain, as Clifton-Mount, the favourite mark, touched 143s, and Radnor 142s, and other estates in proportion. A large shipment went home by the "Orinoco," which has been held by the brokers in Liverpool; so we are all hoping for equivalent results, for prices have been going up steadily lately in London in consequence of reduced stocks, and also no doubt because the Brazil crop of eight million bags is not forthcoming, for it can only have been the anticipation of this immense supply which has kept coffee at moderate prices in the face of largely diminished European stocks.

Whilst talking of coffee, reminds me to ask whether you or any of your readers came across a note in the *St. James's Budget* of the 17th July, in which Monsieur Raoul, in the employ of the French Government, an eminent botanist, is represented as having calmly stated that he had visited the principal coffee-growing districts in the world, and had scarcely met with a plantation that was not seriously affected by "*Hemileia vastatrix*," which is as disastrous to the coffee, as the *Phylloxera* is to the vine. Now I have written to the editor of the *St. James's Budget* (who, I trust, will deem my letter worthy of publication) to prove I trust very practically that M. Raoul's statement that in a few years prices of coffee will rise to four times their present value, and that it will be difficult to find a substitute—to be an opinion entirely at variance with actual probabilities; for Mr. Raoul has evidently never visited, and palpably utterly ignored, the Western Hemisphere as a coffee producer. Though he avers he has visited the principal coffee-growing districts in the world, I think God, we are so far from the date past, which makes Mr. Raoul's statement in great measure correct as regards the Eastern Indies, though even there old King Coffee is not entirely wiped out. Why! Brazil alone would pretty well supply the wants of the European and American markets, to say nothing of Central America, and the much ignored and despised West Indies. I think, therefore, there is not much chance of coffee rising in value to such a price, as to deprive all but the rich from indulging in the concoction of the berry which sustains

and cheers and does not inebriate; at the same time barring any disaster such as befall coffee in the East Indies, I believe that West India and all coffee planters on this side of the world may hopefully look forward to the maintenance of paying prices in the Home markets for whilst population must, as a natural consequence, increase, the production of coffee on the other hand is not likely to be augmented in like proportion; for Brazil, now that the slaves are freed, will most likely produce less, than increase its exports, and as to the West Indies and Central America, though there are thousands of acres of land available for cultivation, labour and transport difficulties, both as regards the cost and the scarcity of suitable labor, must prevent to any material extent the increase of coffee plantations, for we old planters all know that without moderately priced labor and other facilities it is impossible to grow coffee at a reasonable profit. The latter part of the article on which I have based these remarks not only *rites* but likewise amuses me, I mean the editor's remark that "in this country we have long since learned to thrive on very passable imitations, the calamity will not be felt at its worst," and as criticism on this very "naive" view of the prophesied scarcity I naturally ask in my letter "Why have the people of Great Britain calmly consented to this adulteration? And why have British Governments, one after another, refused to accord to coffee planters the same protection as to growers of other products, which are strictly guarded by laws prohibiting mixtures; but with coffee if a grocer merely labels the coffee as not pure coffee, he may mix any sort of trash with it, and thereby make very large, and what I as an honest man deem dishonest profits, cheating and hoodwinking the public, especially the poorest classes, and defrauding the Government, who appear blind to the fact of the extra revenue that would be derived were more genuine coffee consumed in Great Britain, instead of decreasing as has of late been the rule, proving conclusively that adulteration obtains to a great extent.

Another old Ceylon coffee planter has appeared on the scene—Mr. E. L. Mackenzie. He was in Ceylon from 1876 to 1879 until bad times and fever compelled him to return home. He managed latterly Dr. White's estates in Uva: he now desires to return to his former love, and will, I trust, be able to meet with a suitable property and settle down amongst us. As to F. D. Marshall, formerly of Haputale, I am sorry to say he has given up coffee planting, and is now employed by Government on the railway staff. With Dr. Plaxton, who has charge of the Jamaica Lunatic Asylum and Major Knollys, Inspector-General of Police, we have now a total of five men who, at various times, have been denizens of dear old Ceylon. Would there were more of them, and that we had enough of our old Madras coolies to help us, though how we should be able to feed them with our transport difficulties, having to carry the rice some 11 miles on mules' backs, would be a puzzle, so perhaps it is as well to put up with Mr., Mrs., and Miss Quashie, and submit to the ways and customs of our adopted country.

The Legislative Council met on the 26th ultimo: as regards the question of the re-adjustment of taxation, the Governor in his Message stated that the revenue had improved, and would be sufficient to meet the last year's deficiency, and that as 1888-89 would probably leave a small surplus, he therefore deemed it best to postpone any further legislation as regards taxation to next year, when the new Council will have been elected, and be

concluded that the elected members, representing the different Parishes, will, by that time, have ascertained the wishes of their constituents, and come fully prepared to legislate on such an important subject.

In Kingston a new Council has been elected, and Mr. Jackson, a lawyer, has been chosen as Mayor. Let us hope the change will be for the better, and that the most important matters of proper drainage and sewerage of the town, and the building of a ship-quay and dock, will be taken in hand. To show how little public spirit and patriotism there is in Jamaica, the fact that not half of those who had votes to elect members of Council took the trouble to come and vote, and also that many suitable men who were elected refused to serve, speaks for itself.

We are to have an "assistant" Bishop, as our present Bishop, Dr. Enos Nuttall, is far from strong, and very much overworked. The Venerable Arch-deacon C. F. Donet, M. A., of Trinity College, Cambridge, was unanimously chosen by the Synod and went home by the last packet to be ordained.

W. S.

COFFEE AND GREEN BUG:

A SYMPOSIUM OF PLANTING AUTHORITIES: A VARIETY OF OPINIONS.

A well-known Udapussellawa planter put a question to us some weeks ago which we scarcely felt competent to answer. We accordingly asked the opinion of a number of visiting agents and residential estate managers in different districts still having to do with coffee; and the result, though scarcely so encouraging as we had hoped, is worthy of being put on record at this period of our planting history. Our friend originally wrote to us:—

"Do you think, reasoning from analogy, there is a probability of this green bug coming to an end, after it has run a course of a certain number of generations?"

"That is my belief: Can you support it in any way? It does not kill cultivated coffee, and when estates are half in tea, they could afford to wait until the evil had past its worst and was on the decline.

"Any sane man can see that coffee will soon be worth its weight in gold."

On this a well known Visiting Agent remarks:—

"The attack of green bug this year in Dikoya and Maskeliya is not so general and not so virulent as last season. In Dimbula also it is less prevalent, and in the old districts, the little coffee left is comparatively free of it. The above facts certainly favour the assumption that the pest is on the decline, although it appears to me rather premature to jump to conclusions. Green bug has killed cultivated coffee."

Another "V. A." and resident Manager sends us a long letter on the subject as follows:—

"WILL GREEN BUG LEAVE US?"

ANALOGOUSLY CONSIDERED.

"SIR,—I have seen the note for your paper in which a well-known Udapussellawa planter inquires whether there is any likelihood of the green bug, which attacks coffee, coming to an end?"

"I believe the worst pests which trouble modern agriculture, indeed I may say trouble mankind, are those which I shall call 'exotic,' and that there may be no want of clearness in what I mean I will give a few illustrations. *Ageratum* and *lantana* are both exotics, also that widespread wild and very beautiful sunflower or marigold that may now be seen growing alongside our roads throughout the length and breadth of the Central Province. The plague which ravaged Europe some centuries ago, and which appears now to have died out, and the cholera are both of the same nature: they having arisen in the east and travelled westward. These

are all governed by the same general laws and struggle for their existence in much the same manner as we do ourselves and our cultivated plants; but I must return to my exotic theory.

"It is generally well known now that in South America, from whence we obtain vanilla, there is an insect provided with the means of fertilizing the flowers, while here in Ceylon there are no insects so provided; consequently only those mature here which by means of wind and other indirect causes are fortuitously fertilized. All this goes to show how necessary is the condition of our surroundings to our lives and the welfare of our plants and animals. The smallest germ may produce the direst disease. Tapeworm may assume two or three different forms in which it can enter the human system. I cannot tell you to how many millions an original aphid can increase in an incredibly short time if its surroundings are favourable; neither can I tell you how many millions of aphides a few thousand ladybirds can suck, as schoolboys suck gooseberries in the same period of time, but I believe the number has been recorded.

"This green bug, which has troubled us so much, belongs to a family whose habits are very similar to the aphid family, and it is assailed by much the same kind of enemy, who looks him over, chooses a nice spot, and then sucks him dry. There are doubtless many other insects and fungi who, had they the chance, would probably treat him even more roughly, and I wish for your Udapussellawa friend that I could find the right individual to introduce.

"All this tends to show that there is a balance in nature corresponding to our so-called balance of power in Europe, only deranged when some being runs 'amok' as did Napoleon Bonaparte nearly 100 years ago, and it is the adjustment of this that is wanted when coffee is so heavily handicapped with the green bug. Nature's equipoise has been overcome for the time.

"My theory of leaf disease and green bug is, that both have been introduced into Ceylon in some wardian case, maybe at Peradeniya, arriving possibly upon the most improbable plant,* without their natural enemy, so when let loose again have had their undue share of prosperity. The same applies to *ageratum* and *lantana*. If their natural and indigenous enemies could only form a part of their environment, their demise, or at least their blatant audacity would be followed by the most retiring modesty. An instance we have in the introduction of the rabbit into Australia without its natural enemy the fox. Were the fox and the weasel both introduced along with the rabbit, it would probably have been kept within bounds; the one would make the rabbit "lie out" and then the fox would fall upon him. Unfortunately, the latter has a partiality for lambs, and this prevents its being favourably regarded.

"Coffee, like an oak, a man, or a butterfly, has its allotted period of life; a time comes to all when their tissues are worn out and they die,—this we call old age. Their lives too are affected by the vicissitudes accidental to them in the struggle for existence. With man there are diseases which Life Assurance offices consider shorten life, even after recovery appears secured; this also is the case with plants and animals. Green bug at first was so intense in form and character as in some instances causing immediate death to coffee; it is, however, not as insidious as leaf-disease, so there is more hope for its subjection through many enemies which subsist upon it; thus wherever its appearance has not resulted in prompt and irremediable evil, these would remain, and if they do not destroy it altogether would keep it within such bounds as to be more or less under human control; neither do I consider green bug has the same power for evil when its enemies are established amongst it as it had at the beginning of its attack. The aphides and

* This is contrary to the opinion of the late Dr. Thwaites, a most learned mycologist, who distinctly stated that *Hemileia vastatrix* existed in the jungles of Ceylon (in which there are trees of the family to which coffee belongs) in a latent form, before it got upon the cultivated coffee.—Ed.

scaly bugs are much sought after by many predatory insects which would increase and form part of the environment of coffee wherever and whenever the pest was present. The degrees of their influences are dependent upon many causes, although I think your correspondent may rest assured after the first two years, that the worst form of the evil has passed. Such has been the result of my observation in various districts; besides, the existence of such tempting food as scaly-bugs in vast numbers cannot long remain without collecting around them ever fresh and increasing swarms of rapacious enemies. How far the coffee tree has suffered in its constitution in the meantime is also a factor in determining its period of successful cultivation after the enemy has left the scene of its undesired labours?—APHIS."

We next come to a gentleman who like "Aphis" has had a long experience of coffee in a variety of districts:—

"When your Udupussellawa correspondent says 'It does not kill cultivated coffee,' I do not know what he means, or where he has been. I have no hesitation in saying it has killed cultivated coffee within the last year. Whole acres in Maturata have gone clean out, and been cleared away to make room for tea. The manager of 'Seaton' estate, Maturata, wrote me no later than last current:—'The coffee about the store has become black with bug' (green bug). Glasgow estate is far away from Maturata, but even there we have suffered badly from green bug, and though it is not very bad at the present moment, it may return again in full force whenever the dry weather sets in. I consider Mr. ——— is extremely sanguine in this matter, and I think there is nothing to show that green bug is leaving us. I would be only too glad to think he was right, but I cannot see it. I drew Mr. John Brown's attention to an invention at home for destroying such pests, viz. Strawson's a machine which can be run over a farm by one horse, and can cast a fine spray of kerosene oil at the rate of 6 acres an hour. It does no harm to vegetable life. The effect is as of a spider's web of a fine morning after rain, covering the bushes. If we could run it by means of coolies along our estate roads, and spray even 4 acres in an hour or two, we might soon dispose of insect pests. I hope Mr. Brown will be able to bring out a machine suitable for our requirements, and so enable us to keep coffee free from insect pests.

"We have not, however, got rid of our old enemy, leaf disease, yet. The fall of leaf just now is as bad as it has ever been."

An Uva planter writes:—

"If our friend could answer the question 'What number of generations is bug going to run?' we might be able to give our opinion if coffee will hold out long enough, but I fear it is quite a mistake to suppose that green bug does not kill cultivated coffee. At all events it so thoroughly impoverishes and weakens the lungs of the coffee, that in many instances the trees become like dried sticks and die off in patches.

"I do not advocate cutting out coffee affected by bug so long as a hope remains of its producing crop to pay cost of upkeep; but I cannot too strongly urge the opinion that while sticking to the coffee thus affected, the planting of tea, where means are available, should not be delayed.

"Very little can be said in support of coffee outliving this most serious of all pests that have attacked our old staple. I have 100 acres of this estate without a berry, and but for bug it would have given a good blossom. This no ordinary proprietor can stand if it goes on year after year; yet I have seen coffee, worse than any I have, recover apparently. Unless the course of green bug is about its close, coffee must go, as I say: in many instances it is going on in patches, and much of the coffee that has been frequently attacked by bug is so weakened, that it cannot mature the crop as it did in former days."

Mr. Geo. Wall writes:—

"I know no reason why the green bug should disappear after any number of generations. It will per-

sist as long as the conditions which favour its propagation last, whatever these may be.

"The black bug, when it first visited our plantations, spread over nearly the whole country, and disappeared very soon over the greater part; but it lingered in certain localities in different parts of the country for 10, 15, or even 25 years, to my knowledge. In some of these places every remedy was tried in vain. In one case, after numerous efforts, to extirpate it had been tried in vain, the trees were cut to the stump and the primaries left with only one eye each. The leaves and branches were burned and the tree stumps were scoured and limed. The result was that the young leaf buds that came upon the trees that survived the treatment were thickly beset by the bugs as soon as they appeared!

"My experience of the green bug is that unless destroyed it will kill the coffee trees. At any rate I have not known any to withstand a persistent attack of 3 years."

Next, we have the valuable opinion of Mr. Giles F. Walker of Bogawantalawa:—

"November 2nd, 1888.

"I do not know whether there is any scientific chance of green bug dying out of itself, but black bug seems to afford an analogous instance, so that we may not unreasonably expect the present pest, if not to go away completely, yet to assume a mildly chronic form, which would do comparatively little harm.

"Mr. ———'s assertion that this bug does not kill 'cultivated coffee' depends upon the meaning you attach to the expression 'cultivated.' Used in the loose general sense, cultivated coffee has undoubtedly been killed to a very large extent. That we should have suffered less had we manured more liberally goes without saying: but how many men could afford to risk the expense of heavy manuring in the face of the earlier ravages of the bug aggravated by leaf disease?

"The bug this season is in these districts much less severe than it was last year, though it is still present here and there more or less. If it is tending towards a milder chronic form we can combat both it and leaf disease very largely, by more liberal cultivation; and we can afford to do this in view of the present and prospective prices of coffee.

"We are by no means 'out of the wood, yet, but I would certainly advocate the retention of all good and fairly healthy coffee and the careful pruning and handling of it under any circumstances.

"Each year no doubt sees a further acreage on every estate, over which coffee has to give place to tea; but, so long as any doubt remains, I would give coffee the benefit of that doubt.

"A good thorough forking up of the soil with 15" grapes I have found very beneficial to trees that have suffered from bug or leaf disease, and the cost of this is not heavy."

Again, a gentleman of experience in Southern India, as well as in inspecting estates in Ceylon, is good enough to answer our inquiry as follows:—

"When on my rounds I received the note from you respecting 'green bug' and the value of coffee as a product.

"In the first place, I would remark that since I came to Ceylon I have gradually formed the following opinion, viz., that leaf-disease and green bug have been the result of want of tillage of the soil, i. e., deep forking; after many years of hand weeding and a considerable portion of the land covered with moss, &c., the land has become sour. Then again, *shade* has been too much neglected, I mean the planting of proper shade trees when coffee was planted in the field. I know all the varieties suitable to the Indian climate, but would say that *Ficus glaberrima* would be the best for Ceylon where the climate is not too wet. I have planted this year at Kondesale 50 acres of cacao with coffee (iron-wood seed) and the above fig trees as *shade* the coffee is 6 by 5 and cacao 12' by 10' shade the same.

"I am led to make these remarks on 'shade,' because in South Coorg, where the coffee is under cultivated shade and the land is well forked at least once a year,

black or green bug and leaf disease are unknown; again more shade means more variety and less chance of attacks from epidemic diseases, or the advent of such as the green bug. The question, however, I have run away from: it is asked if you think it will disappear? I think judging from the black bug, and we can have no better analogy, that green bug will disappear in the near future, and that every planter who can afford to feed his coffee with manure and bide his time, should do so—it is what we are doing for our Company, and I am glad to say that, where, on one estate in Dimbula, we had green bug on 110 acres of coffee, it cannot be found now.

"If the above remarks are of any use in helping you to form a conclusion and assist Mr. —, I shall be glad; I am far too busy to write anything more deeply on the subject just now. I used to hear much about the *poor* soil in Ceylon, but I find that a large area had very rich soil and bore successive crops of coffee unequalled even by the Oucherlonny Valley."

We leave the above variety of opinions from planters of much experience and generally resident in different districts to the consideration of our readers. We have certainly heard from more than one quarter of green bug killing coffee trees, but these trees had undoubtedly been previously debilitated by the leaf fungus. Scale insects are well known to be amongst the greatest enemies of horticulturists and planters, and they sometimes kill individual trees, but there is no instance within our knowledge of a great industry being destroyed by them. We cannot venture to prophesy, but we have every hope that those who possess really good coffee can successfully fight green bug if *Hemileia vastatrix* abates its virulence. Just as we are writing, there comes a letter from the Chairman of the Haputale Planters' Association announcing the appearance in that district of what appears to be, apparently, a new tiny moth which spreads over the coffee in millions. Mr. Westland hazards the suggestion that they may be feeding on the bug; and we have referred his letter and the specimens he has sent to Mr. Green. The result of the latter's inspection will be awaited with interest. Meantime, it will be a pity if Mr. John Hughes should not have the opportunity, while amongst us, of seeing Mr. Vollar's fine sheet of young coffee on Pallekelly and some of the well-maintained coffee fields in Udapussellawa, Agrapatana or Dikoya. It seems to us, indeed, that there is room for a small committee of inquiry as to the likelihood of coffee grown from Mysore seed at a moderate elevation and *under shade* resisting the leaf fungus and green bug as in the case of the Dumbara fields, and the Coorg and Mysore estates which are positively increasing their exports. [The climate of the Mysore coffee districts resembles that of Uva in being for a large portion of the year rainless: droughty, indeed. Such climate seems to indicate benefit from shade.] There are capitalists interested in Ceylon who would probably take such a Committee's Report, if favorable, as a strong inducement to invest in coffee on carefully selected blocks of chena, if not forest, land under, 3,000 or 2,000 feet elevation.

THE TEA TRADE OF JAPAN.

CONSULAR REPORT FOR 1888.

(From the *Japan Weekly Mail*, Nov. 3rd.)

The export figures for the port of Yokohama for tea show a slight falling-off as compared with 1886 both in quantity and value, being 26,557,616 lb valued at £732,311 against 27,836,925 lb valued at £829,538 in 1886, being a decrease of 1,279,309 lb and £97,120.

The trade was an unsatisfactory one to exporters, as they had not only a somewhat inferior crop to handle, owing to the weather during the growth of the leaf not being so favourable as in the preceding

year, but a considerable portion of the previous year's supply remained over on the American and Canadian markets, and as a consequence, the new leaf did not meet with the demand anticipated by some buyers. This reacting upon the Japan market caused dulness and lower offers for what remained of the crop here, but the Japanese dealers kept prices up, and shipped a considerable quantity of tea on their own account, forming several companies for the purpose. These shipments, having no legitimate outlet, and being thrown upon the markets from unaccustomed channels, were recklessly sold in the central markets of New York and Chicago, and, as they served to increase the previous excessive supply, they produced a depression and low range of prices such as had never before been experienced in the United States and Canada.

The crop was a large one, and of fair average quality, and prices during the entire season, though unusually even, ruled slightly higher than the previous year, though the general tendency for a series of years has been to lower rates owing to steady increase in production, which has been greater than the increase in demand for consumption. The decline in silver has had the effect of maintaining prices at higher rates than would otherwise have been the case, and the business evidently continues to be remunerative to the producer.

A noteworthy feature of the year, as regards the effect on the British carrying trade in tea, was the falling off in shipments by the Suez route, the greater portion of this decrease amounting to about 4,000,000 lb (or say 6,000 tons of 40 cubic feet measurement), being carried across the Pacific Ocean by steamers running in connection with the Canadian Pacific Railroad.

CINCHONA CULTIVATION IN JAPAN.

The following is a translation of Mr. van Romunde's report, dated Tirtasari, 10th October 1888, on the Government Cinchona enterprise in Java for the third quarter of 1888:—

During the past quarter the weather continued pretty dry. At the beginning of August and the end of September some showers fell, which did much good to the young plantings and especially to the nurseries. On the whole the plantations continued to grow well, thanks especially to the thorough working of the soil during the east monsoon, with the exception however of a large portion of the graft plantations at Tirtasari, which were badly affected by caterpillars. In the past quarter about 250,000 half-kilograms of bark were dispatched. The crop of 1888 therefore so far amounts to some 500,000 pounds of bark, of which by the end of September 405,303 pounds had been dispatched to Batavia. On 7th June, 17th July and 30th August sales of cinchona bark were held in Amsterdam. The prices obtained at these were very encouraging as regards ledgeriana and officialis barks. Pharmaceutical barks of good appearance and desired form also realized satisfactory prices, whilst a strong downward tendency is to be marked in the price of inferior varieties of cinchona, especially of those barks which are not distinguished by a handsome appearance. During the quarter three of Davidson's T Siroccos were erected at Tjinjroean and Tjibeureum, which, on account of the plentiful harvest, were at once set agoing. During the course of October similar drying apparatus will begin working at Tjibitoeng, Rioenggoeng and Kawah Tjiwidi. At the same time at Lembang a drying furnace of simple construction will be built, so that now on all the establishments harvesting can be proceeded with uninterruptedly independent of the state of the weather. At Tirtasari caterpillars made a renewed attack upon the ledgeriana graft plantations and did considerable damage there. The plague was checked as far as possible by the catching of the insects. It is specially the older plantations, where the catching of the insect is well-nigh impossible, that suffered most from the plague. The damage

done was aggravated, as the trees had to endure an attack of *Helopeltis antonii* immediately after the ravages caused by the insect. Surprise is caused by the phenomenon, that in the neighbouring seedling plantations of Tjinjroean there was scarcely a trace of a plague of caterpillars. At Tirtasaria commencement was made with the clearing of forest land intended for the laying out of graft plantations. Our account of the plentiful supply of grafts in the nurseries the above establishment can be extended by about thirty bouws during the last quarter of this year and the first half of 1889.

The total number of plants in the Government gardens at the end of the quarter was 3 720,000 made up as follows:—In the nurseries, 2,1 57,000, viz., 1,870,000 ledgeriana (including 45,000 grafts); and 287,000 succirubra. In the open, 1,563,000; viz., 821,000 ledgeriana (including 200,000 cuttings and grafts, and exclusive of the more or less 3,000 original ledgers), 8,500 calisaya and hasskarliana 611,900 succirubra and caloptera, 121,500 officinalis and 1,000 lancifolia.

THE DUTCH CINCHONA AUCTIONS.

(Telegram from our Correspondent.)

AMSTERDAM, Nov. 8th.

At today's periodical auctions of Java cinchona bark about 107 tons of manufacturers' bark were offered, analysing as follows:—9 tons from 1 to 2 per cent; 17 tons 2 to 3; 28 tons 3 to 4; 18 tons 4 to 5; 14 tons 5 to 6; 5 tons 6 to 7; 10 tons 7 to 8; 4 tons 8 to 9; 1 ton 10 to 11. The average quinine standard being 43 per cent. Of the packages offered, 1,592 were disposed of at prices equal to those realised at the London auctions this week, the unit averaging 11 cents, or 2d per lb. The prices paid range from 10 to 76 cents (=1½d to 1s 1½d per lb.) for druggists' quills; broken quills and chips, from 17 to 23 cents (=3d to 4½d per lb.) for ditto root; from 14 to 110 cents (=2½d to 1s 8d per lb.) for manufacturing bark, quills, broken quills, and chips; and from 43 to 82 cents (=7½d to 1s 2½d per lb. for manufacturing root. The principal buyers, in order of importance, were Messrs. Zimmer & Co., of Frankfort-on-Maine, the Brunswick Quinine Works, the Amsterdam Quinine Works, and Messrs. O. L. Schepp & Zoon, of Rotterdam.—*Chemist and Druggist.*

FINE NILGIRI TEAS.

We have received from the Manager of Glendale estate, Coonoor (the property of Mr. Thomas Stanes), samples of the fine delicate teas sold in September last in London at 7s 6d and 6s. The former is called "Young Hyson" and Mr. Stanes says is not difficult to manufacture. In place of the Black Tea which sold at 6s, the Manager Mr. Brown seems to have sent us a sample of 35 boxes of Golden Orange pekoe which sold at 2s 1d. Both samples are however very interesting and can be seen at the *Observer* office.

A merchant, who has seen the samples, writes:—"We have had a good look, and have liquored, with the result that they may be described as follows:—

"Golden Orange Pekoe.—Black, bright, even wiry leaf, full of golden tips, infusion bright and even, liquor very thin. Fine delicate flavour.

"Young Hyson.—Straw-coloured apex, very thin, very pungent.

"The latter is quite a rarity, and I have nothing like it produced in Ceylon, in a commercial way at all events."

TOBACCO PLANTING IN SUMATRA.

AN IN-CEYLON PLANTER CRITICISING AND OFFERING COUNSEL ON THE CURING OF TOBACCO.

DEAR SIR, November—*Observer* and *T. J.* regularly to hand, and read with great interest. It was a

great shock to me to hear of James Cantlay's death. He was a good and sincere friend, and I look back now, alas, many years ago, to pleasant and happy days spent in his house, both in Medamahawara and Dimbula; there was no one I knew in Ceylon for whose opinion I had greater respect.—R. I. P.

Some time ago I noticed in one of your articles ament the profits made by Deli planters, that it was no wonder that I and others were reticent on the subject of Tobacco, meaning, I suppose, that we liked to keep the secrets connected therewith to ourselves. Well, for my part, you accuse me unjustly: I would gladly impart to one and all of the Ceylon men, who choose to go in for tobacco, everything I know about the mysteries (?) of curing tobacco; but the fact is, it is impossible for me, or anyone else, to tell on paper or by word of mouth how the leaf is fermented. It can only be learned by experience, not the experience of a year or so, but an experience requiring the closest study and attention of at least four or five years, and even then I am doubtful, if one has not much to learn. Every year every estate shows different qualities of tobacco, which require different treatment, and he would be a bold man, even among the planters here, who would say to his neighbour, you should do this or that; you may have your ideas on the subject, but it is wisest to keep them to yourself, or you may run amuck, a thorough knowledge of the tobacco undergoing fermentation being indispensable.

I see in your *Overland* issue of the 9th ult. an extract from a letter from a Mr. Gray, in which he says he has got over the problem of curing, and that he has cured 10 cwt. or so. Well, if by curing he means fermentation, he must allow me to tell him, that, if he has fermented 10 cwt of tobacco, he has wrought a miracle, and deserves to get the "good man with capital," when doubtless he will soon make his 10 per cent. It is one of the difficulties we have, in opening a new estate, which is generally on a small scale, say from 60 to 100 fields (a field is generally about an acre and one-third, which is the amount given to one cooly to cultivate), to get sufficient tobacco to ferment properly; we cannot do so with a small quantity, even 300 piculs, equal to about 360 cwt., gives great trouble: it is one thing to dry the tobacco, another to ferment. I should like to learn how Mr. Gray raised his temperature with 10 cwt. of tobacco; I expect if he turned over this quantity a couple of times, he would find that he would get no higher temperature than the surrounding atmosphere. Our tobacco generally takes from 6 to 7 months, from the time it enters the fermenting shed until it is out fermented, but it greatly depends on the quality of the leaf, oily tobacco taking much longer than dry. Out fermented tobacco can be told *only* by the touch and look, not by the thermometer.

Mr. Gray says the three main points in curing tobacco are:—1st, to fix the colour required; 2nd, retain flavour and strength; 3rd, to secure a leathery texture. As to the first, neither Mr. Gray nor any other man can fix the colour required (I only wish we could); we can fix no colour; the colours are inherent, and are brought out by fermentation. We cannot cure the tobacco yellow, though by time fermentation a darker shade may be got. The second and third are rather more the tree is cut, but something can be done to get lighter or darker original colours by cutting at different degrees of ripeness, but it would take too long to explain this, so will pass on to the 3rd main point. If Mr. Gray was fortunate in curing, he need not bother himself about the strength and

flavour; they will look after themselves. 3rd, if Mr. Gray and all others interested in tobacco in Ceylon will only continue to secure a leathery texture, we here will have nothing to fear from Ceylon competition; our great desideratum is to secure as *fine and silky a leaf as it is possible to get*; but Mr. Gray, having solved the problem, doubtless knows what he is writing about.

"Peppercorn," in his jocular manner, puts a question from the young tobacco planter to the older about the number of colours; for the information of the would be T. P.'s I will tell them. There are only four principal colours, viz., dark brown, vaal (Dutch), nearly equivalent to our fawn colour, and yellow; but there are, of course, many shades, and it requires a practised eye to tell what particular colour the leaf should be assorted to.

It is one of the greatest difficulties we have to deal with, the sorting of the tobacco, and I am sorry to say, with all our practice and experience we are still far from being perfect; not that the manager or his assistants do not know what to do, but the difficulty is to get the coolies to do it, and when you come to think that on an estate producing, say 1,000 piculs, 25 millions or more of leaves have to be assorted, each to its particular kind, and on most estates 17 or more different kinds are sorted, you can conceive the very great difficulty there is in getting the work anything like properly done.

In writing you the above, I simply do so with the wish to bring before those, who may think of investing in tobacco, that there are many, many difficulties to contend with in the preparation of the leaf, and that those difficulties can only be got over by actual downright hard experience, and not by reading manuals or essays, be they ever so cleverly written.

In the course of my experience in the East, now upwards of 20 years, I have seen most tropical cultures, and I can safely say, that there are none, that requires so much careful study and attention for some years as the preparation of tobacco. The mere growing of the tobacco is nothing, as it is more or less mechanical work.

I am sorry to see Fritz Meyer's experiment in Kurunegala has failed through drought; better luck next time. Crops here are short, as a rule, this year we trust to prices keeping up. Last year's crop, so far, has not always realized satisfactory prices, the Amsterdam market showing a decline of about 25% in the previous year's prices; still some favorite marks have realized splendid prices. A. F.

COCA LEAVES.—The advertising columns of our daily issue show that there is a chance for any planter who has been cultivating the *Erythroxylon Coca* of finding a market in Colombo for his leaves. The object is to extract cocaine.

A PINEAPPLE MONSTROSITY has been sent to us by Messrs. Volkart Brothers with the following note:—"A native gentleman, Mr. F. Fernando, of Kollupitiya, brought us this morning the monster pine herewith. We do not know whether it is anything very extraordinary, as we often saw several pines growing on one stem, although probably never any with 10 to 11 fruits as this one. It was grown in Mr. F. Fernando's garden, about 8 miles from Colombo." The monstrosity weighs 31 lb., and is 21 inches in length, 31 inches in breadth, and has a circumference of 73 inches. We noticed a similar abnormal growth some time ago, but this one is a good deal larger. Of course it is quite uneatable.

THE RUMOUR as to the forthcoming Tea Trust, to which we referred last week, is exciting much curiosity. The names of those connected with the project are not made public for the present, but should it be in the hands of men likely to inspire confidence, the Trust should be a success. There is plenty of room for an undertaking of the kind.—*H. & C. Mail.*

THE PUNAC TRADE WITH THE STRAITS SETTLEMENTS.—A very brisk trade is being carried on between Pondicherry and Penang in earth-nut ponac. The steamers "Roma" and "Menatchy," bound for that port, shipped upwards of 9 000 bags, or nearly 700 tons, during the last fortnight. The price at present is R8-8-0 per candy of 529 lb. English. Two years ago the value was but a little more than one-half that amount.—*M. Mail.*

A NEW CEYLON TEA ESTATES Co.—We call attention to the remarks given in last Overland Summary in reference to the New Dikoya Tea Estates Company for which Mr. H. L. Forbes is advertising for a Manager. The name of the new Company has not yet been fixed. The estates included will be: Invery, Waterloo and Strathdon in Dikoya district, Mincing Lane in Maskeliya, and Abergeldie and Benachie in Lower Dikoya, comprising a total of 1,526 acres with 1,426 acres in cultivation almost entirely tea and most of it just coming into bearing.

A NEW PERFUME PROCESS.—A firm of manufacturers at Leipsic, who are known as distillers of essential oils on rather a large scale, are reported to have discovered a process for extracting and preserving the musk perfume from the ambretta or musk seed. It is said that should this process really prove to be practically useful, the consumption of ambretta seed would probably increase very largely. It is now estimated at about 25,000 lbs. weight a year over the whole world. It is not a little curious that just as this news reaches us, we learn that most of the Java cultivators have ceased to grow the plant which yields this now-to-be-famous musk seed. Some time ago it was stated that fourpence a pound, which is all they can get for it, does not cover more than one-third of their expenses. Whether the ambretta cultivation revive or not in Java, we trust we shall hear some day that the new process has proved to be successful.—*Burgoyne, Burbridges & Co.'s Price Current.*

DRIED PLANTS FOR ESSENTIAL OILS.—At a meeting of the New York Pharmaceutical Association held not very long ago, Mr. Albert M. Todd read a paper on the treatment and distillation of peppermint plants. He was particularly desirous of discovering whether the drying of the plant (drying by legitimate means, of course) had any influence on the yield of essential oil. After a great number of laborious investigations which it is not necessary to dilate upon in this place, the author finally arrived at the following conclusions:—1st. In peppermint and other plants yielding essential oils no perceptible loss of essence is occasioned by drying in the open air at ordinary temperatures. 2nd. When the drying of the plants is continued through many months, a slight oxidation of the oil in the leaf occurs, decreasing its solubility and increasing its specific gravity; this resinification also raises its boiling point, for the resin formed is non-volatile and insoluble. 3rd. A long exposure of the plants to atmospheric action prior to distillation does not affect the crystallising tendency of the essential oil of peppermint, nor any other of its physical properties, as far as the author has investigated them. 4th. To obtain the best results the plants should be dried thoroughly, and distillation should take place as soon as possible afterwards. With regard to the latter conclusion, we should add that 2000 lbs. of dried plants yielded 20 lbs. of oil in thirty minutes, and a similar charge of fresh plants yielded only 2 lbs. of oil in an hour. The plant loses about half its weight (49.4 per cent) on drying by exposure to the sun in the open air. This loss of weight is entirely moisture.—*Burgoyne, Burbridges & Co.'s Price Current.*

Correspondence.

To the Editor.

THE OPENING FOR CEYLON TEA IN SOUTH AUSTRALIA:—PRACTICAL PROPOSALS.

Gawler Place, Adelaide, S. Australia,
19th Nov. 1888.

DEAR SIR,—I have noticed in your *Overland* issue just to hand the proposal to send a Christmas box of Ceylon tea to all the editors in America, and further that it has been also suggested to do the same in Australia. Now as regards S. Australia, there are only about 40 editors, the cost would not be much to send each of them a 3 lb. box of tea, with pamphlet, giving a brief description of the tea industry from the commencement which would prove interesting in itself, and would undoubtedly cause notice to be taken.

We have found very satisfactory results from sending 1 lb. packets to private families, which has paid much better than all the advertising done from time to time.

As regards distribution for South Australia, we are willing to take it up on the following terms:—

That the tea be put in 3 lb. boxes; quality—a good pekoe or pekoe souchong. We agree to pay half the cost including freight and insurance, the duty and other charges on this side to be paid by us. And for the supply of further orders it must be understood the pamphlet to bear our name and address, so that all orders would come through us. Should the Planters' Association see fit to agree to the above, we shall forward a draft for our share with as little delay as possible.—We remain, yours faithfully,
DRUMMOND BROS.

AN INSECT ENEMY OF TEA.

Dolosbage, 24th Nov. 1888.

DEAR SIR,—By the post that takes this to you I send you a matchbox containing some insect poochie which I took off one of these estates and which appears to be doing sad destruction to the tea plants amongst which I found it; fully an acre had been destroyed by it. The leaves on every tree that it attacked were completely riddled as if shot at by the finest sized shot, and were covered with a bright yellow tinge, something the colour of that created by *Hemiteia vastatrix*. They also appeared as if spiders had been over them, and many of them were mere skeletons, and quite like a gossamer web. There were some *gedumba* trees in the neighbourhood here ones that were full of the insect, and the whole tree looked as if a burning fire had passed over it, the leaves all dropping off; every piece of vegetation that it attacked was a pitiful sight to see. I notice too that it is quickly and greatly increasing; some measures have been taken to stop it, but not sufficient to arrest its progress.

After a few fine days we have the rain on us again, but it will do good, as flushing appears much retarded since the wane of the moon.—Yours faithfully,
BLIGHT.

The leaves sent are covered with the cast skins of a species of hairy caterpillar which I am unable to identify in this state. 'Blight' letter send five specimens." So says our scientific referee. Meantime the Dato bugs planters concerned should take steps at once to destroy the *gedumba* trees from which the insect is said to have spread. The insect looks like a "green fly," but further live specimens are necessary to identification.—Ed.

THE HAPUTALE MOTHS.

Haputale, Below the Pass, 27th November 1888.

DEAR SIR,—During the past few days there have been thousands, perhaps millions, of moths like the enclosed flitting about amongst the coffee affected by green bug.

It has occurred to me to send you these specimens, in the hope that your friend Mr. Green may be able to enlighten us as to the object of their mission.

Are they destined to eat up or spread the bug? Or are they simply enjoying a short and merry life without doing either good or harm?—Yours truly,
AN OLD COFFEE TREE.

[Mr. A. P. Green reports:—"A small moth belonging to the *Tineide*, not likely to affect the green bug in any way."—Ed.]

GREEN BUG.

December 5th, 1888.

DEAR SIR,—Considering the time which has elapsed since the so-called "highest cultivated" coffee districts of Ceylon have been dead—killed by green bug—it is astounding to see this question in print:—"Does bug kill cultivated coffee?" Surely the gentleman who proffers it, has suddenly awakened from a trance of many years' duration! He is marvellously behind the times. Unfortunately, experience knows too well that wheresoever the highest cultivation obtained, there the collapse, under green bug, was of the most abject kind; such coffee, for instance, which one sees in the neighbourhood of coolies' lines, proving in this respect absolutely the most contemptible! One season was sufficient. Upon the other hand, the few ghostly, desultory coffee sticks which linger throughout the districts which were first visited by bug apparently owe their existence still to the fact that they have been left severely alone; participating only in the weeding, which, however, is not done upon their account.

In this connection, there may, awhile, come a little coffee from Uva, the constitution of its trees not having been utterly wrecked by castor cake and bone dust *et hoc*. And for this brief reprieve, thankfulness should be due, that the means, whereby the vast majority of coffee properties met their ruin 15 years before their time was withheld: there was no railway to Uva.* A fragile thread of hope is clung to and hails from the higher districts: it is that "bug is not so bad this season as last, and appears to be wearing out." Is it? It thus so seemed in the lower districts last year, but 6 months of renewed excessive virulence have since divided the wretched fragments which remained by 2. There is no hope for coffee. This is how a valuer of a new estate "comes estate" would act: he would estimate the value of the crop upon the trees, adding thereto the "prairie" value of the land—price R10 per acre—which would be considered, with a possible view to being put under tea by-and-bye. But upon the coffee trees he would not put the value of one cent per acre, so long as the improbable supposition that they would be dead, 9 months hence, was not guaranteed by anything more substantial than "hope." Were he to act otherwise, his proper place would be in a lunatic asylum. The gentleman who lays down this profound opinion—"That green bug is due to sour soil, induced by hand weeding"—adds one more item to the voluminous rubbish which has been printed in Ceylon for 20 years in connection with suchlike kindred subjects.

* Our correspondent is well-known as a promoter of "cyclops"—Ed. C. O.

A very good shot can be made whence pests are propagated, but who upon earth knows their origin? It is quite believed—and with truth—that the opening of jungles in Madulsima was responsible for *H. vastatrix*, and all its consequences: hence we dearly love that district. But it is not quite so certain that green bug, which is more deadly than 16 years of leaf-disease conglomeration, was not introduced by Liberian plants in wardian cases. At all events, 4 years ago this question was publicly put: "Was this bug in Liberia, upon Liberian coffee, when Liberian plants were despatched to Ceylon?" This question, no notice was taken of it, and what makes it more suspicious is the fact that green bug seems a permanent and comparatively harmless parasite of the Liberian coffee tree and as familiar as are buffaloes and ticks. Moreover its first appearance in Ceylon was upon Liberian coffee, not one hundred miles from the north road, where it recruited strength and started thence upon its gruesome journey, collapsing district after district, like so many ninepins.

If it was Liberian coffee which brought the bug, I subscribe myself one of the earliest victims of the introduction by others of a

"NEW PRODUCT."

LOSS IN WEIGHT OF CEYLON TEA SENT TO LONDON.

The Hermitage, Kandy, Dec. 6th, 1888.

SIR,—Loss in weight of tea has been alluded to by your "London Correspondent." Beside the usual draft 1 lb. per package allowed, there is an actual loss as per enclosed extract from a London letter, of 2 per cent; on other occasions I have had it a good deal more. Now, sir, the question is, where and how does this loss occur? If Ceylon exports thirty million lb. of tea during the current year, and there is a loss on it of 2 per cent over and above the usual draft of 1 lb. per package, what pickings there must be for some people? Fancy 60,000 lb. of tea which has been securely boxed, leaded, and soldered on the estate, going into *thin air*! We poor deluded planters chucked at the idea of packing up our own produce and dodging the Colombo curing charges. We are not a whit better off, in fact, I may say, worse off, as I cannot remember loss in weight of coffee anything like what it is in tea. A story has been told me by a sampling clerk, which goes far towards confirming my suspicions, regarding malpractices at the London warehouses. My informant relates, that samples taken from the packages were looked upon as *the property* of the clerks, and were regularly sold, and proceeds divided amongst them! As an illustration, he tells of how he took what he considered fair samples on his first visit to the warehouse, but the old stagers very soon opened his eyes and told him to bring paying quantities in future!!! If our teas are dealt with in this manner, it is indeed needless to combat against loss, except by very powerful machinery.—I am, sir, &c.,

SHELTON AGAR.

COFFEE IN WYNAAD.—Taken as a whole, we hear the coming coffee crops will scarcely realise estimates. A few estates in Wynaad, which were fortunate to get the early showers to bring forward a large April blossom appear to be the exception to the general rule. During the early part of last year, and especially during the months of June and July, the rainfall was excessive, but this year the early showers throughout Wynaad and Coorg appear to have been unusually deficient. This, however, it appears has not affected the highly cultivated estates so much as the ones lacking this advantage.—*South of India Observer*.

MEXICAN AGRICULTURE.—In a recent report on the agriculture of the Mexican State of Vera Cruz, the British Consul describes the primitive manner in which maize is cultivated in the Minatitlan district, where three crops are raised annually, but never on the same land. No ploughing is done; one man makes with a pointed stick a series of lines of holes about two feet apart; another man follows, dropping two or three grains into each hole, and the rain is left to fill the holes in. The harvest is calculated at a hundred times the weight of the seed, and is gathered in 16 weeks after the planting. No manuring is done, except when the land is first cleared, and then the ashes of the burnt underwood, rank grass, and stumps are used as fertilizers. This method of cultivation prevails in remote and low-lying districts: on the higher levels maize is cultivated on ploughed lands, and farming there is becoming more and more systematic, and on many haciendas scientific. Lack of capital is the cause of the exceedingly rude cultivation of cotton, maize, and other products in Mexico. Even in the case of tobacco many planters never plough or manure, and never plant the same land twice, yet the reputation of Mexican tobacco is rapidly increasing, and the manufacturers of Vera Cruz are increasing the size of their factories and the number of their operatives. The present annual production is almost 6,000,000 lb., produced at an average cost of 5½d. per lb. Twenty-three per cent. of the whole is exported, about half of which is manufactured and goes chiefly to England.

THE INFLUENCE OF SUNLIGHT ON TREES.—In the latest report of the head of the Forestry Department of the United States reference is made to the effect of light on the growth of various trees. It is well known, says Professor Fernow, that light is necessary for the development of chlorophyll, and therefore, for the life of all green plants, and especially for that of trees. The heat alone which accompanies the light is not sufficient, although the relative influence of the light and the heat on the growth is still an open question, as well as the relative requirements in light of different species of trees. In the case of forest weeds, which in forestry serve as an indication of the amount of shade which the trees exert, and with that their capacity of impeding evaporation, some require full sunlight for their development, others are averse to a high degree of light. To this must be due the change in the plants of a district when its forests are removed. Then the amount of light or shade needed is modified by site. Where the sunlight is strong, in higher altitudes, drier climates, or where the growing season is longer, or there are more sunny days, some species will endure more shade. The flora of high altitudes in general requires light. Trees nearly always develop best, in other words, make most wood, in the full enjoyment of light, but their capacity of developing under shade varies greatly. The yew will thrive in the densest shade, while a few years overtopping kills the larch; the beech will grow with considerable energy under partial shade, where the oak would only just keep alive and the birch would die. When planted in moist places all species are less sensitive to the withdrawal of light. In the open, maples, elms, sycamores, and others grow well and make good shade trees, in a dense forest they thin out and have but scanty foliage. Conifers, such as spruces and firs, which preserve the foliage of several years, have perhaps the greatest capacity of growing under shade, and preserve the foliage in spite of the withdrawal of light. In America sufficient data to group the forest trees according to the amount of light required by them have not yet been collected, but rules based on experience have long been formed in Germany, where the behaviour of trees under different conditions of light has been carefully studied. It has been found, for instance, that on the same branch those leaves which are developed under the full influence of sunlight are not only larger and often tougher in texture, and thicker, but that they have a larger number of stomata or breathing pores than those less exposed to light. The whole subject is one of the utmost importance in forestry, and observations and experiments are to be carried out in regard to it in the United States.—*Times Weekly Edition*.

NEW INDUSTRIES AND DEVELOPMENT OF THE NORTHERN HALF OF THE ISLAND.

AN ECHO FROM THE NORTH.

Your recent editorial utterances, in the widely read columns of the *Observer*, will, I hope, go a great way to wake up many a Jaffnese from their long lethargy of indifference. Among the many industries and works, which you have called upon the Jaffnese to undertake, those of palmyrah planting development of inland steam navigation, and the manufacture of cement, must before all receive their early attention. It is a lamentable truth, that the first industry does not at all receive any attention from the people, and if this state of things continue, it is to be feared that the race of palmyras might become extinct, whole gardens of waving palmyras are annually emptied for the sake of timber obtainable from them, and no effort is ever made to plant others in the place of those that are dislodged. The great demand in India for this timber is the cause of this annual wholesale slaughter. It is a very shortsighted policy indeed to look for a present immediate gain and to be blind to the great and continued good that would result hereafter.

It was a good custom of old, in the villages and the many islands that lie scattered about Jaffna forming a veritable archipelago, that no sooner a daughter was born in a family, than the parents of the child made it their first business before anything else, to buy some acres of waste or Crown land and plant them with palmyra seeds; so that when the child arrived at woman's estate and was to be married, this piece of land was given to her as her dowry. By the time the daughter was of age to be married, the palmyras would be in full bearing, and the new family lived on the produce. It was by such good and wholesome practice as this, that lands which would have otherwise been overgrown with jungle, were converted into gardens of waving palmyras; but it must be mentioned to the shame of the present generation that the practice has altogether fallen into disuse, and no effort is made to revive such a useful custom.

Your suggestion about insisting on every traveller by the Jaffna-Kandy road to plant two or three palmyrah seeds along the sides of the road, by way of toll, is an admirable one indeed; but whether this is practicable, is a doubtful question. The region of palmyra at present extends from the very north of the Jaffna peninsula to Elephant Pass, but there are stray ones here and there farther down on the east coast. There are upwards of twenty coach stations between Elephant Pass and Anuradhapura, and if persons in charge of each station be asked to plant 200 or 300 seeds about their houses, this number alone will amount to 4,000 or 5,000 plants; and, as the distance between two stations is at the most 5 miles, this gap can be slowly filled up by travellers according to your suggestion. But for the present, I believe, this suggestion of mine will work admirably well, if the coach contractor can be made to take some trouble with it, and the plan can be carried about at little or no cost.

About your second suggestion, viz. the development of inland steam navigation, I think you have briefly put forward the several advantages which would accrue from this movement. Suffice it to say, that this will be a move in the right direction, and one worthy of the attention of all intelligent Jaffnese, both at home and abroad. With regard to your doubt, whether there exists a large trade to justify the introduction of steam launches, I may say there exists enough of trade to cover all the expenses of keeping up steam launches and to leave a fair margin of profit. There is a large trade carried on between Kayts on the one end and Elephant Pass on the other, a distance of about 30 miles. Most of the paddy and rice imported into the peninsula is brought down from Kayts—a harbour where native vessels anchor, as the lagoon is not deep enough for this purpose. There is again a long uninterrupted line of coconut estates from Cavakachcheri to Elephant Pass, a distance of about 25 miles, and cutloads of coconuts and copra are daily brought into the town. Now transport is very expensive, and this will be conferring a real boon

to coconut planters. Besides this extensive trade there is an annual transport of tobacco, paddy, and other things from those places, and above all there is timber to be transported all the year round, and if every other thing fail, any Company can safely rely on the last mentioned trade. The lagoon is deep enough to admit of steam launches of light draught. As the steam-launches can bring boats in tow, and as they can ply about the lake all the year round, their introduction will not prove detrimental to the interests of boat owners, but on the other hand, trade will be kept up uninterrupted with every place in spite of the changes of monsoon which at present put a stop to trade with many places. One of these can be used to carry mails and passengers to Mannar from Jaffna, another can go round to Kankasanturai and Point Pedro to bring down in tow boats laden with paddy and other articles; one more can constantly ply between Jaffna and Kayts, in view of the large trade between the two places, carrying mails and passengers in addition, another still between Jaffna and Elephant Pass. Thus there is work enough for four or five moderate sized steam launches of light draught, and these being available all the year round, will be doing a world of good to the Jaffnese. But it is easy to say things like this and thousands more, and it is for the Jaffnese to take vigorous steps in this direction, especially at this time when there is the Agent of the Province well versed in these things, and not to sit folding their hands and clamour for railway, as frogs in a pond. The fact is that enterprises like this require large capital, and, as this is solely in the hands of the ignorant few, it is next to impossibility to persuade them to undertake things like this. As this is hopeless, we look for our rich and intelligent brethren in Colombo and elsewhere to initiate this movement, and make their names ever remembered by the people of JAFFNA.

DRUG TRADE REPORT.

LONDON, November 15th.

ANNATTO.—Several parcels of Brazilian Roll annatto were again offered. Most of these are now rather hard and off colour, and holders appear rather anxious to dispose of them. They accepted 10s per lb. today for 50 baskets. For seven cases Ceylon Seed mixed with dust and stones and quite discoloured 3d per lb. was offered.

CARDAMOMS.—The quantity offered at auction today was again a very small one, viz., 55 cases only, mostly of Mysore variety. By far the greater part of the supply was sold with excellent competition at an advance of from 3d to 5d per lb. all round. Mysore, good long pale 2s 5d to 2s 6d; (2s 7d being refused for a slightly better lot); medium to small pale 1s 11d; yellow and rather dull medium long 1s 9d; medium to bold mouldy grey 1s 8d to 1s 10d; small to medium brown and specky 1s 7d; very small long pale 1s 4d; Ceylon-Malabar, yellow mixed round warty 1s 5d; small and dark 1s; Aleppo, fair brown 1s 4d to 1s 7d; Tellicherry, dark and husky 6s 1d; Seeds 1s 7d to 1s 9d per lb. The exports from Ceylon between October 1st and 18th have been:—1888, 6,720 lb.; 1887, 1,936 lb.; 1886, 6,015 lb.

CINCHONA.—A rather heavy quantity of south American barks offered at today's sale was brought extremely high prices, especially for Loxa and Huancoco barks, which were well represented, and sold in many instances at 3d to 4d per lb. advance. Loxa bark in good bright broken, quills brought 2s 3d per lb.; broken, dull, and damaged ditto from 1s 11d down to 1s per lb., while a very badly damaged lot sold at 4s per lb. Huancoco, Ac., fine mussy 2s 1d; bright thin broken quills 1s 7d to 1s 4d; rusty dull and split quills 1s to 7d per lb.; a lot of common damaged Guayaquil at 2s per lb. Seventeen bales common hard Puyo are held at 1 1/2 per lb., while 3 bales coarse and badly damaged Maracano sold at 1 1/2 per lb. Of flat Calsaya bark 2 serons very fine bright hard bold orange sold at 2s 3d per lb.; other less desirable lots being bought in at 2s to 1s 5d per lb. nominally. Ordinary broken quill wood at 8d to 3d per

lb. For 14 cases thin but very long (4 feet) rusty Java quills, analysing 2.13 per cent quinine sulphate, and 5.62 per cent total alkaloid 9d per lb. was refused. The arrivals in London have been very heavy since our last reports. With regard to last week's auctions in Amsterdam, the average percentage of quinine sulphate in the bark sold there was 4.3 per cent, and not 3.75 to 4 per cent as has been stated in other quarters. The quantity of quinine in the bark sold was apportioned as follows:—

Amsterdam Quinine Works, buying also for the Maunheim Works	Kilos.	1,320
C. L. Schepp & Zoon, Rotterdam	...	840
Brunswick Quinine Works	...	820
Zimmer & Co., Frankfort-on-Maine	...	750
Other buyers together	...	960

Total ... 4,670

CLOVES sold at the weekly auctions at a decline of ½d to ¾d per cwt. Zanzibar, dark to fair, 9½ to 9¾d; good fair 9¼d; good bright 9¾d to 9½d.

COCA LEAVES.—Steady. Five bales good bright brown mixed Huanoco leaves sold at 1s 2d per lb. today. Another lot, not so good, was bought in.

CUBEBS.—Eight cases were imported this week per "Dardanus" from Singapore. At today's auctions 37 packages of various qualities were shown. Four bales of these (of which no sample was shown) were sold at £24, for 19 bags small but genuine, very slightly mixed and stalky berries, £26 is required; and for another lot of the bold berries, which many here consider spurious £22 15s was refused £24 being named as the price.

QUININE has had an extremely uninteresting week. German bulk is now quoted at 1s 4½d per oz. on the spot in second hands at the auctions; 100 1-oz. bottles of Pelletier's make, imported in May, 1871 sold without reserve at 1s 8½d per oz.

THE AMERICAN MARKETS.

NEW YORK, October 27th.

QUININE shows not the least improvement, though possibly the next few days may develop some change in the position of the article. London has been cabling to this market "active business" and "advancing prices," with the value up to 1s 6d, or equivalent to 36c. for German in large bulk, but the information has been without influence, as buyers have, stood, and stand today ready to meet the wants of the trade at 32c. to 33c. Confidence is also lacking in the position of this staple, very few in the trade seeing anything of a favourable character in the outlook—*Chemist and Druggist*, November 17th:

OUR CINCHONA REPORTS.

SIR,—Permit us to take the liberty of drawing your attention to an item in your otherwise so interesting and complete market reports that possibly might create false ideas about the capacities of the various quinine factories. Of late, namely, you give statements of the quantities of bark bought in the various auctions, together with the names of the respective buyers, without, however, considering the percentage of quinine in the bark bought, nor the relative values of the lots. Thus it happens that factories appear to be at the head of the buyers who in reality purchase little proportionally. One factory in particular buys almost exclusively bark of a very low percentage, and if the amount of quinine in bark were taken into consideration, this factory would not appear such a large buyer as is now the case, but generally rank far lower in your reports than it does. The following explains our meaning:—"The Auerbach factory bought 141,307 lb." (see page 445, September 29th); "the Auerbach factory bought 117,858 lb." (see page 521, October 13th). But these quantities contained only 2,100 and 1,750 lb. of quinine respectively, and were therefore barks of not even 1½ per cent average. We bought 29,401 and 31,800 lb., representing about 1,650 and 1,250 lb. of quinine. These quantities, it is true, are somewhat smaller than those bought by the Auerbach works, but not at all in the

proportion the bark figures might make it appear, since the bark bought by our factory averages 5½ and 4 per cent, therefore more than three times the average of the quinine standard of the Auerbach barks.

It would, therefore, be an improvement if in your highly-valued report you could take this point into consideration in a similar way as with the reports on the Amsterdam auctions. This, no doubt, will be easy for you, as the official London analyses surely are easily obtainable by you.—Very truly yours, ZIMMER & Co.

Frankfurt a. M.-Sachsenhausen; October 22nd.

—*Chemist and Druggist*.

A QUININE SPECULATION.

Some three years ago a gallant attempt was made to found a new British quinine factory at Widmore, near Bromley, in Kent. The enterprise was undertaken by a German gentleman named Schütte, who had been already established in London in business in the export drug trade, and who probably thought it desirable to be ready for the boom in quinine which has been so long coming. Building land was taken at 35l. a year ground rent, a convenient factory was put up at a cost of nearly 2,000l., and it was furnished with special plant, costing, it is said, about 9,000l. The plant included eight large torpedo-shaped bark-extractors, crystallising pans, boilers, engines, tanks, hydraulic and other presses, the fittings of an experimental laboratory, &c. The factory was "going" for about a year, and a certain quantity of "Widmore" quinine was put on the market. We have not heard that any complaint was made of the quality, and we believe it realised ordinary prices. No time could have been more unfortunately chosen, as it turned out, for the investment of ten or twelve thousand pounds in quinine works, and the latest scene in the history was reached on Wednesday afternoon, when Mr. F. J. Bisley, auctioneer, invited offers for the concern at the Mart "by order of the mortgagee." Less than a score of people attended, and very little anxiety was manifested to become the proprietor of this desirable possession. For the whole property, building and plant complete, the best offer made was 1,500l.; for the plant alone no advance on 250l. was recorded; and the auctioneer intimated that both these figures were considerably below the limit, though he said he had come there to sell if anything approaching a reasonable sum had been obtainable. The chance is probably still open.—*Chemist and Druggist*, Nov. 17th.

FINE NILGIRI TEAS.

Our Colombo broking correspondent expresses the following opinion on Glendale tea samples:—"They are both beautiful teas; the young Hyson especially, which is worth all the money. The other tea (black) looks cheap against some Ceylons I have seen as tippy and well-made. The 'green' is as pungent as they make them, and is the top leaf and undeveloped bud only, or 'tip' as it is called when 'tea.' I certainly should have valued it at 8s. to 9s. per lb. and the O. P. at 2s. 6d."

TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon "Tea Fund" held at Nuwara Eliya on Thursday, the 6th day of December 1888, at half-past 3 o'clock in the afternoon.

Present:—Messrs. L. H. Kelly, Chairman, Planters' Association of Ceylon; H. K. Rutherford, Chairman Kelani Valley Association; H. L. Forbes, Chairman, Ambagamuwa Association; G. A. Dick, Chairman, Uda, pussellawa Association; G. F. Walker, Chairman,

Dikoya Association; G. A. Talbot, Chairman, Dimbula Association; J. H. Starey, Kandy, R. Porter, Kandy, and A. Philip, Secretary, Planters' Association of Ceylon.

I. The notice calling the meeting was read.

II. The minutes of proceedings of a meeting of the Standing Committee held at Nuwara Eliya on Friday, the 12th day of October 1888, were read and confirmed.

III. Read letter from Mr. Edward Hamlin intimating that the directors of the Oriental Bank Estates Company (Limited) have authorized the continuance of the Company's subscription to the "Tea Fund" for another year on same terms as before.

IV. Read letter from Hon. Thos. North Christie acknowledging receipt of resolution regarding Government grant towards the efficient representation of Ceylon tea at Paris Universal Exhibition 1889, and intimating that he will have pleasure in attending to the request of the Committee.

V. Read letter from Mr. T. S. Dobree in reply to resolution of the Committee at last meeting.

VI. Read letter from Messrs. Lee, Hedges & Co. Resolved:—"That in reply Messrs. Lee, Hedges & Co. be informed that subscription to the 'Tea Fund' is not compulsory, but that the Standing Committee hopes that Messrs. Lee, Hedges & Co. will not think of discontinuing their subscription to the 'Fund,' as in the opinion of the Committee the necessity for the 'Fund' is as great as ever, and the Tea Fund Committee have numerous engagements still to carry out."

VII.—Read letter from Mr. W. Taylor, Darrawella, Dikoya, in reply to the resolution of the Committee passed at its last meeting.

Resolved (1):—"That Mr. R. R. Taylor, Trinam, Canterbury, New Zealand, be appointed an agent of the Planters' Association of Ceylon in New Zealand, the conditions of the agency being that the only tea Mr. Taylor shall sell is *pure Ceylon tea*." (2.) "That Mr. Taylor be further informed that the Standing Committee of the 'Ceylon Tea Fund' does not see its way to sending him a grant of tea at present, as such grants are confined to entirely new fields."

VIII—Read letter from Mr. Walter Agar explaining that under certain conditions he is quite agreeable to continue his subscription to the Tea Fund and would certainly support the Fund provided results shows its operations to have been good.

GRANT OF TEA FOR FREE DISTRIBUTION IN NEW ZEALAND THROUGH MR. J. FENTON WINGATE.

Read (I) letter from Mr. Wingate; (II) letters from Messrs. J. M. Robertson & Co., Colombo, intimating the purchase and shipment of six hundred and twenty (620 lb) of Ceylon tea to Port Lyttleton, New Zealand and enclosing invoice for R495/94, also letter acknowledging payment of this amount.

GRANT OF TEA FOR FREE DISTRIBUTION IN THE CITIES OF THE ARGENTINE REPUBLIC THROUGH MR. T. C. ANDERSON.

Read (1) letter from Mr. T. C. Anderson; (2) letters from Messrs. J. M. Robertson & Co. intimating the purchase and shipment of four hundred and sixty pounds (460 lb.) Ceylon tea and enclosing invoice for R261/86 also letter acknowledging payment of this amount.

CEYLON TEA IN AMERICA.

The Pineo-Elwood May Scheme for Taking Up and Pushing the Sale of Ceylon Tea throughout America.—

Read letter from Mr. R. E. Pineo and other correspondence on the subject. Resolved:—"That in answer to Mr. Pineo's letter dated 6th December and from the information received by the Association the Standing Committee of the 'Tea Fund' considers it inadvisable to recommend to the Association the appointment of Mr. S. Elwood May as its agent in America for the sale of Ceylon tea."

PARIS UNIVERSAL EXHIBITION 1889.

Submitted correspondence on the subject.

LONDON COMMITTEE.

Resolved:—"That the Secretary be instructed to ask Mr. Whitball and Mr. Leake to associate themselves with Mr. Shand in carrying out arrangements for the 'Tea Room' at the Paris Exhibition."

GLASGOW INTERNATIONAL EXHIBITION 1888.

Submitted correspondence on the subject.

Resolved:—"That Mr. Shand be informed that the Planters' Association's show cases may now be sold to best advantage on account of the Association."

BRUSSELS INTERNATIONAL EXHIBITION 1888.

Submitted correspondence on the subject.

MELBOURNE CENTENNIAL EXHIBITION 1888.

Submitted correspondence and telegrams on the subject.

Resolved:—"That in addition to the vote of R6,000 already made a further sum £100 sterling be granted to the Melbourne Exhibition, and that this sum be remitted at once to Mr. Hugh Mackenzie, also that 2,000 lb. of Ceylon tea be purchased, if necessary, and shipped to him for sale, the value to be repaid through Mr. Mackenzie by bank draft."

The Standing Committee of the "Tea Fund" then adjourned.

A. PHILIP, Secretary, P. A. of Ceylon.

COCONUT PLANTING IN THE WESTERN PROVINCE:

MANURING AND DIFFERENCES OF OPINION—AGRICULTURAL CHEMISTRY—BONES NOT STIMULATING.

Siyane Korale, Nov. 1888.

As silence on my part on the remarks aimed at me in the notes on coconut planting by your veteran coconut planting correspondent is likely to be misunderstood, I take up my pen to answer them.

My definition of manuring, as restoring to the soil the elements of fertility removed by cropping, cannot be and is not questioned. The definition is general. I have been misrepresented in the application of that definition to the purposes of coconut cultivation. I have systematically opposed the teaching that it is wise to force young trees into premature bearing by the application of bones. Precocity is induced, and this is opposed to longevity. Helping forward the growth of young trees by breaking the soil and the application of such manures as help growth, I have not opposed, and I always carry on this mode of treatment.

"Old Planter" has worked himself up to a state of unnecessary excitement and exhilaration ending with a "hurrah" for a semi-artificial coconut tree! Every planter with a head on his shoulders takes a £ s. d. view of manuring. "Old Planter" labors under the delusion that the system is peculiar to himself. Coconut planters, as a whole, are not singular in their endeavour to make two nuts grow where one grew before. Agriculture is to all, even to the wealthy, a commercial undertaking, therefore the unmeaning hurrah might with advantage have been repressed till it could be used to some purpose.

Does "Old Planter" in all seriousness advance in support of his assertion, that no matter what quantity of manure be placed within reach of a tree, the roots will take up only just sufficient for the requirements of the tree; that the mineral constituents of different species of plants occur in unvarying proportions? Surely, surely so old a hand as "Old Planter" is who has dived into the mysteries of agricultural chemistry for so long, ought to be aware that the proportions of the mineral constituents are unvarying proportionately and not quantitatively. That is, that in every 100 parts of the ashes of the kernel of the coconut there will be found 1.45 phosphoric acid, .21 lime, and so on proportionately, and not that whatever the crop may be the total of the resulting ashes will be as above. What is true of the coconut tree is true of all species of trees and plants and also of animals: whatever the soil, climate, country, food, the proportion of mineral constituents is unvarying. And yet to account for this natural phenomenon there must needs be a resort to endow roots with "super-rational discrimination." If roots do not take up as much as they are able of the nutriment that is within their reach in a soluble state, the appellation given to certain manures as stimulating, unmeaning, and yet

authorities speak of guanos and all manures rich in nitrogen as stimulating. How is the phenomenon of large crops resulting from the liberal use of stimulating manures explained? The reference to the theory of excremental discharges in this connection is not very clear. Before Agricultural Chemistry was an established Science, farmers of observation found out that the same crop will not grow on the same land for a number of years successively. In seeking for an explanation of this, it was believed that plants during their growth excreted certain substances. These were supposed to be injurious to the growth of the plants that were responsible for them, though beneficial to some other species of plants. This was the origin of rotation of crops. But what the exploded theory of excremental discharges has to do with the "super-rational discrimination," with which roots are supposed to be endowed, is not easily understood.

It is well in carrying on a discussion to avoid the use of such high-sounding expressions as "fallacy born of presumption and nursed in the lap of ignorance," "self-satisfied ignorance" &c. However smart one may be considered to be for using them, such expressions have an uncomfortable tendency of recoiling on the head of him who uses them.

The assumption is gratuitous that I am unacquainted with the wonderful successes of "Old Planter" with the coconut plantations once under his charge. Are they not chronicled in Ferguson's Directories, more especially in that for 1876-78, and also in "All About the Coconut Palm," compiled by the same indefatigable gentlemen? In the Directory for 1876-78, it is said that a property 19 years old was taken in hand, and the result was an increase of 50 per cent in crops for the first eight years. In the notes under notice reference is made to a property over 20 years old, the crops of which by good treatment were increased by annual increments 150 per cent. Perhaps both the references are to the same property, and the discrepancy in the figures is due to a lapse of memory. Why is "Old Planter" so kind as to credit me with disbelieving my own visual organs? If I were shown a tree of unusual development with "a space of ten feet between the lowest bunch of nuts and the highest flower," and carrying a crop of 120 nuts, and were told that the tree was 7 years old, and the extraordinary development was due to "15 cents worth of bone dust and 9 cents of labor," I should most certainly credit my informant and my eyes, and find confirmation for my opinion that bone dust was responsible for the abnormal appearance, and that by early forcing, the constitution of the tree would be permanently damaged. Practical, hard-headed coffee planters, who are credited with sound commonsense, and who conducted their cultivation on commercial principles, recommended the stripping of the virgin crop of coffee, which the shock to the constitution of the tree due to topping, to a very great extent induced. Are the abusive epithets levelled at me applicable to them as well, and also to the planters of the present day, who deprecate the early topping and cropping of tea as causing permanent injury to the bush?

I join issue with "Old Planter" when he says that "the sole objective point of all agricultural operations is to get as much as possible out of the land in crops." This is not generally true, however true it may be as regards the cultivation of cereals and root crops. As far as the cultivation of perennials is concerned, I would add to the above "without permanently damaging your trees." On second thought it strikes me that this reservation is unnecessary, as slow and steady returns will ensure the attainment of the "objective point" of agricultural operations, rather than quick and dazzling returns. We are not agreed as to the mode of attaining our objects which are precisely similar.

To say that I preach against the breaking up of the soil and against manuring, is to state what is not the fact. I challenge "Old Planter" to substantiate that, if has any regard for truth, I practise both operations, but not in accordance with the ideas of "Old Planter." I recognise the fact that bone dust is not a general, but a special manure, and I use it with cattle manure and ashes or with oil cake and

potash salts, because I recognise what is a further fact, that in manuring a coconut tree the "objective point" of the practical and wise planter is not only to secure a large crop, but to see that the health of the tree is not injured by the additional strain thrown on it.

Text-books on Agricultural Chemistry say no doubt precisely what "Old Planter" says,—that the oftener soil is stirred the better, for the oxygen and carbonic acid of the air have free access to the soil, and help to render soluble the dormant plant food present in the soil. But we must not blindly follow the teachings of Agricultural Chemistry, we must adapt the teaching to our varied requirements and circumstances. Because frequent stirring of the soil is good in the cultivation of cereals and roots, and is practised when no crop is growing on the land, it by no means follows that the same treatment of the soil must be practised in coconut cultivation. What is nearly analogous to the cultivation of perennials here is fruit farming in Europe. Do farmers practise frequent stirring of the soil of their orchards? Even supposing they do, the circumstances of climate are not identical. In a temperate climate heavy branch and root pruning are necessary to check the natural tendency of the trees to grow wood, and to induce fruit bearing. Here the tendency is just the other way. To show that general rules do not apply even in our little island, I may mention that in coffee planting, heavy pruning and handling were necessary in the higher districts to put crop on the trees, while in the lower districts where no wood was made, very light pruning was resorted to. So with manuring. Planters who followed the fashion of building large central cattle establishments in the higher districts, found them to be a costly failure, while in the lower districts cattle-manure, and in fact all forms of bulky manures, were an absolute necessity.

The sneer at the "choice spirits" among the native planters who dig trenches for manure two feet deep round the tree is uncalled for. I certainly never once came across such trenches, though I move about with my eyes open. As for myself, to receive cattle droppings, I remove soil to the depth of from 3 to 6 inches in a wide circle round my trees, and then dig in the droppings with ashes and bones and return the soil again.

It is due both to "Old Planter" and to myself that I withdraw the term I applied to bones, when I said their action was stimulating. Agricultural authorities tell us that their "effect is spread over a number of years, and that their action is slow," therefore they cannot possibly be stimulating. Where a "gentle but continuous supply of phosphoric acid and ammonia is desirable," bones must be used. To account for the effect of bones on crops, it must be understood that soils as a rule, are deficient in phosphates more so our soils, and that phosphates form a by no means inconsiderable constituent of all fruit and grain crops, therefore the immediate effect of bones is to increase the crop; but as either a crop of grain or fruit requires for its development other constituents besides phosphates, and as an increased crop means an increased demand in the vital resources of the tree, therefore bones must be used with other manures that help towards that end.

There is every promise of the N.-E. rains making up for the deficient fall of the S.-W. monsoon. Already, though the month is only half run out, we have had more rain than for the whole of November 1887. The excessive fall to our human understanding serves no good whatever, at least agriculturally. The soil is so saturated that all the rain we now have runs off the ground. Springs of water start in every direction.

ADULTERATION OF CEYLON TEA.

Planters' Association of Ceylon,
Kandy, 12th Dec. 1888.

To the Editors, "Ceylon Observer."

SIRS,—I beg to enclose a verbatim report of the proceedings at the Mansion House, London, in the case "Regina v. Ellen," received from Mr. Wm. Martin Leake.—Yours faithfully,
A. PHILIP, Secretary.

REGINA V. ELLEN.

Heard 14th November at the Mansion House before Mr. Alderman Knill. Mr. Albert Gray, instructed by Mr. W. J. Crossfield, appeared for the prosecution, and Mr. Poland for the defence.

Mr. GRAY, in opening the case, said:—This is a prosecution under the Merchandise Marks Act of 1887, passed last year for the prevention of frauds in the marking of labels on tea and other descriptions of goods. You will be aware, sir, that these frauds have been the subject of a great deal of discussion in commercial circles.

Mr. POLAND, interrupting, remarked that Mr. Gray was dealing with matters not before the Court.

Mr. GRAY proceeded:—This prosecution is instituted by an Association composed of gentlemen interested in Ceylon affairs, and engaged in business in the City of London. Ceylon tea has attained a good position in the market. The action of the defendant of which we complain is that he has knowingly marked as Ceylon Tea, tea which is largely China tea. (Packet of tea produced.) This packet, sir, was purchased at a shop down in the country. We will prove the purchase. The Act provides that if the retailer will give the prosecution every information that it is in his power to supply, and will prove that he was deceived—that is to say, if he will show that he innocently purchased the tea from the person who applied the false mark: that person and not the retailer, must be proceeded against. In this case it is proved to be the defendant who applied the labels. If you, sir, will kindly look at this packet, you will see that it is entitled "Pure Ceylon Tea" in very large black letters, and underneath is a drawing of a house with the word "Bungalow" added, and at the side in very small letters the words "Blended with the earliest spring pickings of the most noted estates of Assam." You will, sir, apply your own commonsense as to what this description would be taken to mean by the ordinary customer. There is another question. The witness who will be called will state that the tea mixed with the Ceylon tea in the packet is not "Assam," but "China." Witnesses will tell you that a great mass of China tea is sold at Mincing Lane, and at much inferior prices to those obtained for Ceylon tea. If, therefore, this tea was largely "China," a fraud of a serious nature will have been committed in this respect. Great damage is done in this way to the Ceylon tea trade. Advantageous for the China trade, very likely; but even that is doubtful, because the tea is not sold under the name of China tea. I see, sir, that you have a copy of the Act before you, and need therefore only call attention to the special clauses under which this prosecution is instituted. (Chause read.) The tea in this present case has been analyzed by competent men. If the description of "Pure Ceylon Tea" is a false one, most undoubtedly an offence has been committed. It is not as if the label made the words "Blended &c." large like the words "Pure Ceylon Tea." The clause relating to blending is in such small type as to be almost concealed from the intending purchaser.

The next witness was GEORGE W. SMITH, who said:—I am manager to Messrs. Looson, Fishmongers and Greengrocers of Chobham Road, Woking.

Examined by Mr. ALDERMAN GRAY:—About the end of August or September last was a parcel of tea sent to you by defendant?—Yes.

The ALDERMAN:—Did you receive it? Where? the invoice? (Invoice produced dated 28th August; returned by "A. J. Ellen, agent for Bungalow Ceylon tea, packed in parcel.")

Mr. GRAY:—On the terms was this supplied on sale or return? Was there any description on the parcel, or two?

Mr. POLAND:—Why do you ask a question of this nature? It is a question of fact.

The ALDERMAN to Mr. GRAY:—I am beyond your power to ask the witness how many packets of tea there were said to be?

Mr. GRAY:—Carefully.

Witness said that he had always thought the tea was

the same in quality, differing only in price. One was sold at 2s and the other at half a crown.

Mr. GRAY:—Did you sell a packet of tea to Mr. Wainwright? Yes. (Mr. Wainwright identified by witness). What kind of tea did Mr. Wainwright purchase? Two shilling tea. You sent back a considerable quantity of the tea after a time, did you not? Yes.

Cross-examined by Mr. POLAND:—Loe & Son are fishmongers? Yes; and greengrocers. Did you sell tea? Yes. Green tea, of course? No, sir. Then the shop was half a fishmonger's, and the other half a greengrocer's, with a little game thrown in; and occasionally some tea? Yes. Were you asked to buy and sell this tea by the Planters' Association Limited, or whatever the name is? Yes. (Witness afterwards said no.) Then who was it asked you to buy it? Mr. Ellen's traveller. And it was bought on sale or return? Yes. How much of the tea did you keep altogether? Twelve shillings worth. How much of each sort? (No answer.) Have you any that you kept still unopened in your shop? No. Then it's all sold? No; two packets were kept for our own use. They are unopened. That's right you're quite welcome to use it. It's good tea. What sort is it that you have kept. One packet of each sort. Did you know Mr. Wainwright before he bought that tea of you? No. Are you quite sure it is he? Yes, I think so. What colour was the label on the tea? Yellow.

Re-examined by Mr. GRAY:—No other person asked you to purchase the tea besides Mr. Allen's agent? No.

Wm. LANGWORTH WAINWRIGHT said:—I am a medical student, and I reside at Woodside, Weybridge. On the 20th September last I purchased a packet of tea at Loe's shop at Woking. The price was two shillings.

Examined by Mr. GRAY:—What did you do with the packet when you had bought it? I left it at my grandfather's at Woking. And you did not see it again? No. Does your father live with your grandfather? No.

Cross-examined by Mr. POLAND:—You did not buy this tea at your dispensary? I have not a dispensary. Did your father ask you to buy it? Yes, left it at my grandmother's. Oh, your grandmother! You've changed the sex. I hope your grandmother is quite well. Did you hand the packet to your grandmother? No. I left it in the hall. And you didn't put your initials on it, nor mark it with a lancet? No.

The ALDERMAN:—What business is your father in? He has no business.

JAMES GADESSEN WAINWRIGHT, examined by Mr. GRAY:—What is your occupation? I am not engaged in any trade. Did you at the end of September get a packet of Ceylon tea? Yes. I instructed my son to buy it at Messrs. Loe's. How was it sent to you? It came by hand. I don't remember who bought it. I think the packet produced the packet bought to you? Yes, to the best of my belief. Look at the label.

Mr. POLAND:—They are all alike.

Mr. GRAY:—The labels were all the same as that? Yes. What did you with the tea? I took it to Mr. Loe's.

Cross-examined by Mr. POLAND:—To whom did you deliver the tea? To Mr. Loe's.

WILLIAM MARTIN LEAKE:—I am a cement manufacturer.

Examined by Mr. GRAY:—You are interested in Ceylon? Yes; I am interested in London of the Ceylon Planters' Association. On 20th about the 26th of September last you received a packet of tea from Mr. Wainwright? Yes; it was on the 26th. Is that the packet? (Produced.) That is the packet. Was it sent to you? It was sent to me. Did you take any notice of it? Yes; I got a receipt for it. To whom did you deliver it? To Mr. Stanton, and most of it to Mr. Stanton.

Witness said that he had always thought the tea was the same in quality, differing only in price. One was sold at 2s and the other at half a crown. Mr. GRAY:—Did you sell a packet of tea to Mr. Wainwright? Yes. (Mr. Wainwright identified by witness). What kind of tea did Mr. Wainwright purchase? Two shilling tea. You sent back a considerable quantity of the tea after a time, did you not? Yes. Cross-examined by Mr. POLAND:—Loe & Son are fishmongers? Yes; and greengrocers. Did you sell tea? Yes. Green tea, of course? No, sir. Then the shop was half a fishmonger's, and the other half a greengrocer's, with a little game thrown in; and occasionally some tea? Yes. Were you asked to buy and sell this tea by the Planters' Association Limited, or whatever the name is? Yes. (Witness afterwards said no.) Then who was it asked you to buy it? Mr. Ellen's traveller. And it was bought on sale or return? Yes. How much of the tea did you keep altogether? Twelve shillings worth. How much of each sort? (No answer.) Have you any that you kept still unopened in your shop? No. Then it's all sold? No; two packets were kept for our own use. They are unopened. That's right you're quite welcome to use it. It's good tea. What sort is it that you have kept. One packet of each sort. Did you know Mr. Wainwright before he bought that tea of you? No. Are you quite sure it is he? Yes, I think so. What colour was the label on the tea? Yellow. Re-examined by Mr. GRAY:—No other person asked you to purchase the tea besides Mr. Allen's agent? No. Wm. LANGWORTH WAINWRIGHT said:—I am a medical student, and I reside at Woodside, Weybridge. On the 20th September last I purchased a packet of tea at Loe's shop at Woking. The price was two shillings. Examined by Mr. GRAY:—What did you do with the packet when you had bought it? I left it at my grandfather's at Woking. And you did not see it again? No. Does your father live with your grandfather? No. Cross-examined by Mr. POLAND:—You did not buy this tea at your dispensary? I have not a dispensary. Did your father ask you to buy it? Yes, left it at my grandmother's. Oh, your grandmother! You've changed the sex. I hope your grandmother is quite well. Did you hand the packet to your grandmother? No. I left it in the hall. And you didn't put your initials on it, nor mark it with a lancet? No. The ALDERMAN:—What business is your father in? He has no business. JAMES GADESSEN WAINWRIGHT, examined by Mr. GRAY:—What is your occupation? I am not engaged in any trade. Did you at the end of September get a packet of Ceylon tea? Yes. I instructed my son to buy it at Messrs. Loe's. How was it sent to you? It came by hand. I don't remember who bought it. I think the packet produced the packet bought to you? Yes, to the best of my belief. Look at the label. Mr. POLAND:—They are all alike. Mr. GRAY:—The labels were all the same as that? Yes. What did you with the tea? I took it to Mr. Loe's. Cross-examined by Mr. POLAND:—To whom did you deliver the tea? To Mr. Loe's. WILLIAM MARTIN LEAKE:—I am a cement manufacturer. Examined by Mr. GRAY:—You are interested in Ceylon? Yes; I am interested in London of the Ceylon Planters' Association. On 20th about the 26th of September last you received a packet of tea from Mr. Wainwright? Yes; it was on the 26th. Is that the packet? (Produced.) That is the packet. Was it sent to you? It was sent to me. Did you take any notice of it? Yes; I got a receipt for it. To whom did you deliver it? To Mr. Stanton, and most of it to Mr. Stanton. Witness said that he had always thought the tea was

Act the tea in question should have been divided into three equal parts? No; I am not a barrister. So much the better for you.

WITNESS:—That is as it may be.

Mr. POLAND:—You received the tea from Mr. Wainwright? I did. And you personally gave a portion to Mr. Stehn? I did. What is he? A tea taster, associated with Messrs. Wilson, Smithett & Co. And what is Mr. Stanton? A broker. He is a principal. And what about the remainder of the tea? It has been in my possession all the time.

Mr. STEHN was then called, when

Mr. POLAND argued that no evidence had been given to prove that the packet produced was the packet purchased at Loe's. There was proof wanted as to who carried the tea to Mr. J. G. Wainwright, and also as to whether that the tea was the same as had been left by Mr. W. L. Wainwright in the hall at his grandmother's.

After some conversation it was agreed to adjourn the further hearing of the case until Thursday, the 29th November 1888, at 2 o'clock.

Mr. POLAND said, that he would produce proof as to what ships had brought the tea to this country, and would also show by evidence that with the exception of one-fifth or one-sixth the packet of tea sold to Mr. Wainwright was pure Ceylon tea.

An application by Mr. Poland for costs against the plaintiff on the first hearing was refused, the Alderman acceding to Mr. Gray's suggestion that the question of costs might be left over till the conclusion of the case.

GLASGOW EXHIBITION.

Ceylon Court, International Exhibition, Glasgow, 15th Nov. 1888.

The Ceylon Planters' Association.

Gentlemen,—The Glasgow Exhibition is over, and I think Ceylon men have every reason to congratulate themselves on the success of the Ceylon Court and Tea-house here. The former was the most popular Court of its class in the Exhibition, and the success of the tea-house is best explained by the following statistics of cups of tea sold:—

	cups.
May ...	19,058
June ...	18,822
July ...	24,127
August ...	23,946
September ...	22,834
October ...	17,850
November ...	7,865

Total ... 134,512

The tea-house kept up its reputation to the very end, as we sold during the last week 5,881 cups. People are all praising the tea, and there is no doubt that the Exhibition has proved a very good advertisement for the Colony. I am now sitting in the wreck of the Court seeing the familiar old exhibits being packed up and returned, and after eight months of hand work feel thankful not only that the Show is now over, but on account of the success which has marked the Glasgow Exhibition of 1888.—I am, gentlemen, yours faithfully, (Signed) R. O. HALDANE.

PRODUCTS OF THE PINEAPPLE.—A valuable medicinal oil, a sort of wool said to be obnoxious to moths, and a strong, cheap matting, are among the products now made from pineapples.—*Indian Tea Gazette.*

THE work of pushing Indian and Ceylon tea in Scotland and the North of England is assisted by the formation of a company entitled the Indian Tea Bazaar Company, Limited. This Company, the capital of which is £25,000 in £1 shares, has been formed for the purpose of acquiring and extending the business at present carried on in Glasgow, Dundee, Greenock, Leith, Hull, and other places, under the name of "The Indian Tea Bazaars." The business consists of the sale, wholesale and retail, of Indian and Ceylon teas, coffee, cocoa, &c., for house-

hold consumption and otherwise, and the sale of these articles as refreshments in tea and luncheon rooms especially fitted up for the purpose.—*H. & O. Mail.*

RICE IN CEYLON.—*The Reis and Rayget* has the following note:—"After a good deal of effort to make rice a paying crop in Ceylon, the cultivation is to be abandoned. The Government have accepted the view that the experiment has failed. Paddy cannot be grown at a profit." We wonder where our Calcutta contemporary got this information. It was only the other day that a leading Ceylon paper complimented of tank restoration, irrigation, and the over-much prominence given to the encouragement of paddy-growing, albeit it declared its opinion that the Island* is by no means suited to be a great rice-grower. We do not think, nor is it a fact that Paddy cannot be grown in Ceylon at a profit. We may however concede this much, that paddy growing in the north of Ceylon, in the peninsula of Jaffna where running water is unknown, is not appreciably profitable.—"Ceylon Patriot," Nov. 30th.

DELI AND BORNEO TOBACCO.—In Holland the price of tobacco shows a falling off. Overproduction is not the exciting cause. There is always a steady demand for any superior ripe tobacco which yields white ashes. These good qualities begin now to be wanting in Deli tobacco. Dealers ascribe this shortcoming to inferiority in soil, owing to the exhausting nature of the cultivation. Hence Deli tobacco has reached its highest point, and, before long, it will be distanced. The demand calls for good colour, uniform on the whole leaf, which must be moreover sound all through, and without spot or blemish. The recent consignments which reached the market in Holland show spots and burn badly. Their inferior quality has told heavily in depressing prices. Under these circumstances Borneo tobacco has a bright future before it.—*Straits Times*, Nov. 5th.

COIR FOR SOLDIERS' BEDDING.—We regret to find that some serious printers' errors were overlooked in the opening sentences of our short article on the above subject in last week's *Overland Mail*. The passage should have read as follows:—It seems strange that a device for increasing the comfort and healthfulness of soldiers' beds, which has been proved in India to be not only efficient but economical, should still remain unadopted for the Home forces, although the matter has been repeatedly pressed upon the consideration of the authorities at the War Office. Straw for palliasses has been found to be so unsatisfactory for soldiers' bedding that the authorities have long been looking for a substitute. They endeavoured to find it in some form of canvas or netting bottomed cots with extra blankets, but these have been found objectionable from their cost and the want of warmth, etc.—*O. Mail.*

QUININE AND ITS FUTURE.—A good deal of information of interest to cinchona owners will be found on page 450. A planter sends us a cutting from the *Financial News* in which "Verb. Sap." gives his opinion as follows:—

There are various reasons for supposing that these large shipments of bark (from Ceylon) will fall off in the coming year. The very low price of bark will prevent much inferior produce being sent, the absence of disease in trees which have survived, and the impatient owners of estates being now able to make both ends meet with their tea cultivation—all are causes which may result in manufacturers finding themselves short of the raw material they have in previous years been overstocked with. It is very easy and inexpensive to hold stocks of bark or quinine, and it would not require very much capital to hold all that was necessary, not to drive up the price of sulphate of quinine to 15s per ounce, as was done some 10 years ago, but, say to treble its present value.

* We have always guarded ourselves by limiting our objection to certain districts not favourable to rice cultivation.—Ed.

EXTRACTING GOLD BY ELECTRICITY.

Mr. John Taylor, managing director of five of the Kolar Gold Mines, wrote on the 5th ultimo to a mining paper:—"Two tons of Welsh gold ore have been sent to Mr. Colver's electric gold extracting machines. I happened to be present at the drawing of the charge. The plates would not move at first from the superabundance of gold precipitated thereon, but upon extra power being applied they were lifted out, and being placed in the scales they weighed 113 lbs. 7 ounces, deducting 61 lbs. for the two plates left a result of 52 lbs. 7 ounces of pure native gold, the produce of these 2 tons. If these had been treated by any of the present known wasteful processes now being adopted, scarcely one-half of this quantity would have been obtained, as the sulphides of gold are in a great measure lost in manipulation, and as to the silicates they are not realised at all, and are allowed to pass on to the tailings as though they did not exist. How many gold ventures are every year closed through simple negligence and ignorance in treatment of their ores? What an enormous field of enterprise would be opened if these machines were brought to bear upon millions of tons of stuff which are at present simple waste and refuse."—*Indian Agriculturist*.

HOW TO TREAT AN EYE WITH A CINDER IN IT.

A correspondent writes as follows to *The Medical Summary*:—"Nine persons out of every ten with a cinder or any foreign substance in the eye, will instantly begin to rub the eye with one hand, while hunting for their handkerchief with the other. They may, and sometimes do, remove the offending cinder; but more frequently they rub until the eye becomes inflamed, and a handkerchief around the head, and I go to bed. This is all wrong. The better way is, not to rub the eye with the cinder in it at all, but rub the other eye as vigorously as you like. A few years since, I was riding on an engine. The engineer threw open the front window and I caught a cinder that gave me the most excruciating pain. I began to rub the eye with both hands. 'Let that eye alone, and rub the other eye (this from the engineer). I know you doctors think you know it all; but if you will let that eye alone, and rub the other one, the cinder will be out in two minutes,' persisted the engine r. I began to rub the other eye; and soon I felt the cinder jump near the inner canthus, and made ready to take it out. 'Let it alone and keep at the well eye,' shouted the doctor *pro tem*. I did so for a minute longer, and, looking in a small glass he gave me, I found the offender on my cheek. Since then I have tried it many times, and have advised many others, and I have never known it to fail in one instance (unless it was as sharp as a piece of steel, or something that cut into the ball and required an operation to remove it. Why it is so, I do not know; but that it is so, I do know, and that one may be saved much suffering, if they will let the injured eye alone, and rub the well eye."—*Indian Agriculturist*.

GUTTAPERCHA LEAVES AS ROOF TILES.

Those impregnated leaves are made, interwoven two or three-fold in a manner that they cross each other. By this means a thin elastic wooden plate of great power of resistance is formed, which always retains its original form, and, on account of the firmness of the sticking material used, is neither affected by the change of temperature nor weather, and may even be exposed for a considerable time to boiling water without absorbing a particle of the leaves. But for the purpose of still further strengthening their power of resistance, the outer side is spread over with tar, and the inner covered with a layer of warm asphalt, hardened by impressed sand gravel, whereas the inner side is protected against the risk of fire by the addition of a nonconducting matter.

The advantages of this style of roofing consist in the thinness of the plate, compared with the necessary application at ordinary zinc roofs, as well as in the lighter weight. Whereas, for example, a cardboard roof, which was hitherto considered as the lightest, weighs, including the material for fastening, 38 lb. per square metre of roof surface, the guttapercha or Indiarubber plate, prepared as above described, has a weight of only 14 lb. per square metre. As the plates are, moreover, very large, there is no need of any further protection, and they are merely nailed down upon laths placed at a proportionate distance from each other. There is consequently a considerable saving of both labour and cost, and yet the guttapercha roof can be used without support for a comparatively long surface, because its power of resistance against pressure or breaking is most remarkable. *Indiarubber and Guttapercha Journal*.
[The question of cost will arise.—Ed.]

BRITISH AND FOREIGN CONSULS' REPORTS.

DUTCH COLONIES.—The production of arrowroot and indigo in the Dutch colony of Surinam (Netherlands Guiana) is receding, but on the other hand there is an extension in the cultivation of cocoa.
EQUADOR.—**GUAYAQUIL CINCHONA.**—The shipments of cinchona bark from Guayaquil in 1887 were: to the United Kingdom, 3,801 Spanish lbs.; to Spain, 300 Spanish lb.; to the United States, 11,758 Spanish lb.; to France 1,100 Spanish lbs.; and to other parts, 5915 Spanish lb.; a total of 54,877 Spanish lb.

STRAITS SETTLEMENTS.—SINGAPORE. DRUG EXPORTS.—The following articles of pharmaceutical interest were exported from Singapore in 1887, the unit being given in piculs of 133½ lb.: (Gambier (black), 5,038; gambier (cube), 48,260; cutch, 257; gum damar, 5,000; dragons' blood, 47; gum benjamin, 881; copal, 31,354; sticklac, 2,686; nutmegs, 3,473; mace, 172; pepper (black), 178,268; pepper (white), 32,461.

THE PALM OIL TRADE IN ANGOLA.—The palm from which the oil is obtained may be said to be a wild product of Western equatorial Africa, and requires no planting. The fruit grows in large clusters, nearly pear-shaped, or somewhat like a huge branch of very bright red grapes, some clusters counting perhaps a thousand nuts, which are partially embedded in a kind of fibrous matting. The nuts and fruit are the size and nearly the shape of a pigeon's egg, of a bright red colour, tinged sometimes with yellow, and in some cases deepening in shade almost to black. The nut is composed of three parts—the outer covering, the hard nut and the inner kernel. In this respect it is like a plum. The outer covering is from an eighth to a quarter of an inch in thickness, of a fibrous nature, and this contains the oil. To extract the latter the nuts are boiled and beaten to separate the oil from the fibre, which is then skimmed off and put away in pots ready for sale, requiring no further preparation. The inner nut is cracked, and the kernel, which produces a fine white oil, is sold. A few years ago oil from Angola sold in Europe for about 40s per ton; it has now gone down to 20s, and there is said to be no prospect at present of an improvement in the price, because so many substitutes of a cheap kind, notably petroleum, are now employed in manufactures, such as soap, candles, &c., where at one time palm oil alone was used.—*Journal of the Trop.*

A NEW ALKALOID FROM CALABAR BEAN.

Messrs. C. Krieger & Sons of Mannheim, announce the discovery of a new Calabar Bean alkaloid, to which they have given the name "Calabidine." The alkaloid they found is, however, not new to them for many years, and they have made a careful investigation of its chemical and physical properties, and Dr. W. Eber, of Berlin, has reported upon the physiological action of the base. As a result, it appears that calabidine is not nearly an active poison as physostigmine, but it is closely related to it chemically. From the particulars which we have received, we may contrast the properties of the old alkaloid and its new associate—

Physostigmine, $C_{15}H_{21}N_3O_2$.
Melting-point, $106^{\circ} C$.
Very soluble in ether.
Crystallises with difficulty and becomes amorphous on exposure to the air.
Combines readily with acids to form salts.

Eseridine, $C_{15}H_{23}N_3O$
Melting-point, $132^{\circ} C$.
Sparingly soluble in ether.
In crystalline white powder and large transparent crystals, permanent in the air.
Form salts with difficulty.

Perhaps the most important point regarding the new alkaloid is the fact that it so closely resembles physostigmine (there is only a molecule of water of difference in the formulæ) that when heated with acids it undergoes dehydration, and is changed to physostigmine. The physiological experiments with eseridine show that it has a powerful action upon the bowels, inducing copious mucous discharges from the intestinal membrane, without affecting the nervous centres the high degree that physostigmine does. Dr. Eber's investigations show further that the action of eseridine upon the spinal cord is such that its use is contraindicated in diseases wherein there is an excitable condition of that centre. Its action upon the spinal cord is similar to that of strychnine, but it is not cumulative. These particulars seem to indicate that eseridine is not unlike the alkaloid calabarine which Harnack and Wiskowski discovered some fifteen years ago, and which according to them was the tetanising principle of Calabar beans. The existence of this alkaloid has, however, been called in question, the doubts being based on the alleged physical properties of calabarine. We should not be surprised, therefore, if Harnack's alkaloid was found to be a form of Böhringer's eseridine. The latter has been given in the following hypodermic doses to animals, viz., horses up to 0.1 gram, cattle up to 0.2 gram, pigs up to 0.02 gram, and so on. A solution of eseridine, 0.1 gram, with a drop of dilute sulphuric acid, in a few cubic centimeters of water keeps perfectly for a reasonable time.—*Chemist and Druggist*.

AN AGREEABLE DISINFECTANT.

To most of our readers the very words "disinfectant," "deodorizant," and "antiseptic" are at once suggestive of some unpleasant, not to say repulsive, chemical compound, of a more or less caustic, poisonous character, with a "smell about it," too, of the class best described as repellent. Whatever the practical value of any commercial "disinfectant" may be, from a sanitary point of view, its immediate influence upon the noses and the nerves of those exposed to its vapour is often scarcely less objectionable than that of the decomposing organic matter whose evils it is presumably intended to neutralize or counteract.

How many persons, we wonder, really like "carbolic acid," or "coal tar," in any form, or can refrain from shuddering when chloride of lime or bleaching-powder is to the fore? Even Lavarragne's disinfectant, not quite so coarsely bad-smelling as bleaching-powder, is too much for some people, and it seems really to be generally characteristic of this kind of disinfectants that they should exhale a smell of almost cadaveric nature, which readily blends with the sickening emanations arising from the close atmosphere of illness, or the chamber of death.

Ordinary perfumes have but little power to overcome or mask miasmatic smells of this kind, and they were certainly powerless to destroy them, or to paralyse their subtly-dangerous germs of disease.

In "*Eucalyptia*," however—a highly rectified preparation of the essential oil distilled from the leaves of *Eucalyptus Globulus*—Messrs. Burroughes, Wellcome & Co., of Snow Hill Buildings, E. C., have now provided us with a novel and really agreeable disinfectant and antiseptic which, we believe, only needs to be better known to be exceedingly popular amongst medical men, druggists, and undertakers, as well as

with the public generally, during those periods of illness and dissolution which comes to every household in turn.

Eucalyptia is a fragrant, refreshing, volatile oil, which, according to the report of a well-known hygienic authority—Professor Lascelles-Scott—exerts an antiseptic and anti-zymotic action, which, weight for weight, is nearly four times as powerful as that of crystallized carbolic acid, and, therefore, in common parlance, is from twenty to forty times as strong a disinfectant as the fluid carbolic acid of commerce. Unlike this poisonous acid, however—the cause of so many accidental deaths and suicides every year—*eucalyptia* is not deleterious; it may be taken internally without danger (and, indeed, is frequently so administered with great benefit); it may be rubbed upon the skin, and no blistering or cauterization takes place, and, consequently, there is no great harm done even if it be "left about," and "the children get at it." A few drops diffused in spray quickly renders the air of a close apartment wholesome and respirable again, and in every case of death a little should be applied upon and around the corpse, which will then retain its colour, form, and freedom from putrefaction for a comparatively long time. Of course, this is a great safeguard to the health of the living inmates of the house. The term "*Eucalyptus*" has been much abused of late years, and the oil mostly in the market is of a very mixed description, being now often distilled from any and all varieties which happen to be handy. We understand, however, that most of the other kinds are comparatively devoid of *Eucalyptol*—the active principle—but Messrs. Burroughes, Wellcome & Co., have been at much trouble to ensure that their *Eucalyptia* is prepared from the oil of the *Eucalyptus Globulus* only.—*Indiarubber and Gutta-percha Journal*.

ADVERTISING CEYLON TEA.—A firm of London brokers sends us a large poster which they accidentally came across, but which shows the eagerness with which distributors are buying Ceylon tea before the public. The poster is in flaming red and blue letters, and runs thus:—

Co-operative stores Ceylon tea at 2s 4d unknown in England nine years ago.

Ceylon tea at 2s 4d, 14,000,000lb. sold last year in England.

Ceylon tea at 2s 4d, is fresh and fragrant at the stores.

Ceylon tea at 2s 4d, is sold at all the Branches.

Ceylon tea at 2s 4d, it is impossible to buy a better at the price.

Ceylon tea at 2s 4d, is full in colour, flavour, and strength.

Ceylon tea at 2s 4d at the Co-operative stores, where the profits are divided with the purchasers.

ASSAM TRADE means in a very great measure trade in Assam tea, and accordingly it is to the evidence it gives of development in this direction that we mostly look in the recently issued records of river-borne trade for the Province. Some years ago only 337,000 maunds were exported from the Brahmaputra Valley, and 196,000 from the Valley of the Surma; whereas last year the total export in the case of the former was 461,000 maunds, and in that of the latter of 313,000. In the Brahmaputra Valley the prices fell to some extent; but, despite this, both the quantity and the value of the export over the whole of Assam was greater than the outturn of any previous year of which there is a record. Clearly, the rapid advance which the Ceylon leaf is making in the markets of Europe has not as yet at any rate had any prejudicial effect on the prospects of the industry in Assam.—*Pioneer*. [As yet there is evidently room for both, and we trust that demand may increase, so that there always will be.—Ed. T. A.]

MANURE FOR GRAPE VINES.

On the subject of manuring grape vines a writer in the New York *Tribune* gives the following information:—"Good stable manure thoroughly rotted is the best invigorator for grapes; whether organic fertilizers are best for health and longevity of the vine is another question. Application of bones to the grape border is of the greatest importance, as careful examination of the roots will prove. Ground or broken bone is preferable to the material in an unbroken condition, as it allows of a more even distribution and hastens disintegration. Vinoroots, however, will push a long distance in a straight line to obtain this much-coveted food. Some years since in removing a vine it was found that the roots on one side were much stronger than the others, and curiosity as to the cause instigated a careful search for the extremities or feeding rootlets. After several feet had been uncovered the bones of a dead animal were unearthed, but they were so completely covered with a perfect network of small fibres as to be almost indistinguishable. These rootlets had penetrated into very crack or inequality of the bones, which evidently had been of great service as food for the plant. Beyond question iron in the soil is of great benefit for colouring the fruit. Iron filings and turnings answer an excellent purpose, and the effect may be noticeable the first season after application. Above all else the sweepings of a blacksmith's shop have given excellent results, as we then secure manure in a concentrated form and of a variety of constituents—the horse-droppings, hoof-parings, iron-fillings, &c., combine to form a powerful fertilizer. Perhaps no other plant is more quickly benefited by the contents of the washtubs every week. It is a mild solution of potash, and appears to be greedily absorbed at once. A plentiful allowance of wood-ashes forked in the soil in spring pays well in the crop of fruit. It may not destroy mildew on the foliage as some claim, but it will certainly invigorate the plant.—*Adelaide Observer*.

SUCCESSFUL POULTRY RAISING.

Mr. Charles Lyman, a successful raiser of poultry, writes as follows:—"In raising poultry or stock of many kind it should be the aim of every one to keep it healthy and improve it. You can do it very easily by adopting some systematic rule." These may be summed up in brief as follows:—

1. Construct your house good and warm, so as to avoid damp floors and afford a flood of sunlight. Sunshine is better than medicine.
2. Provide a dusting and scratching place where you can bury wheat and corn and thus induce the fowls to take the needful exercise.
3. Provide yourself with some good, healthy chickens, none to be over three or four years old, giving one cock to every twelve hens.
4. Give plenty of fresh air at all times, especially in summer.
5. Give plenty of fresh water daily, and never allow the fowls to go thirsty.
6. Feed them systematically two or three times a day; and scatter the food, so they can't eat too fast or without proper exercise. Do not feed more than they will eat up clean, or they will get ficed of that kind of feed.
7. Give them a variety of both dry and cooked feed; a mixture of cooked meat and vegetables is an excellent thing for their morning meal.
8. Give soft feed in the morning and the whole grain at night except a little wheat or cracked corn placed in the scratching places to give them exercise during the day.
9. Above all things, keep the house clean and well ventilated.
10. Do not crowd too many in one house; if you do, look out for disease.
11. Use carbolic powder occasionally in the dusting bins to destroy lice.
12. Wash your roosts and bottom of laying nests, and whitewash once a week in summer and once a month in winter.

13. Let the old and young have as large a range as possible—the larger the better.

14. Don't breed too many kinds of fowls at the same time, unless you are going into the business. Three or four will give you your hands full.

15. Introduce new blood into your stock every year or so, by either buying a cockerel or settings of eggs from some reliable breeder.

16. In buying birds or eggs, go to some reliable breeder who has his reputation at stake. You may have to pay a little more for birds, but you can depend on what you get. Culls are not cheap at any price.

17. Save the best birds for next year's breeding, and send the others to market. In shipping fancy poultry to market send it dressed.—*Standard American Poultry Book*.

THE ORANGE PEST IN AMERICA: VISIT OF A SPECIALIST TO SOUTH AUSTRALIA.

By the last mail arrived in South Australia Mr. Albert Kœbele, Assistant Entomologist to the United States Department of Agriculture, deputed by that body to visit Australia and enquire into the history and habits of the *Icerya Purchasi* and its parasites, as well as to pick up information generally concerning all kinds of coccidæ and other pests affecting the industrial products of the colonists. Mr. Kœbele is at present living at Botanic House, North-terrace, opposite the Botanic Garden, where he will be very glad to receive information as to where specimens of *Icerya* particularly and other coccidæ (scales, &c.) generally can be seen; or those at a distance who feel willing to help him in his mission can send specimens. The *Icerya Purchasi*, it may be remembered, was supposed to have been introduced at the Cape of Good Hope some few years back, and within a very short time it increased so enormously that the insects utterly destroyed all the orange-trees in that colony, from which trees previously the colonists had derived a very considerable revenue. Not only did it attack the orange-trees, but many other plants also, and nothing could be done to resist its ravages. Finally, the Cape Government interdicted the introduction from Australia of all kinds of acacia and other trees and plants; but the mischief was already completed, and nothing can now be done unless they introduce the parasites which in Australia keep the coccidæ somewhat in check. This course was suggested by our Agricultural Editor to Mr. P. van der Byl, a member of the Cape Legislature, who visited this colony, and he expressed an intention of getting this idea carried out, though up to now no steps have been taken in that direction. Since the ruin of the orange orchards of the Cape of Good Hope the *Icerya Purchasi* has appeared in the Southern States of California, and at Santa Clara, where it first appeared, the trees are in a dreadful state. They are so loaded with the insects as to appear a white mass, visible at a long distance, and all over the States the *Icerya* is spreading so alarmingly that it is only a question of a very short time when the trees will be all dead unless the natural enemy of the insect can be introduced.

It is due to Mr. Frazer S. Crawford of this colony that the discovery was made of this parasite, which proved to be a minute two-winged fly, which deposits its eggs within the body of the *Icerya*. The eggs produce maggots which live upon the juices of their nest, ultimately change into chrysalides, and finally emerge as flies, which again attack fresh coccidæ. Mr. Crawford was unable to successfully introduce the insected *Icerya* to California, but after several trials he got some specimens of a much larger coccid (named *Monophobus*) to California, and from these a variety of the parasite has been introduced. But it is possible that the parasites of the *Monophobus* are of a different species (or perhaps even genus) to those of the *Icerya*, because they would not attack the *Icerya* in California, though

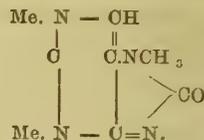

placed under all sorts of circumstances considered to be favourable. Meantime, the United States Department of Agriculture has been most active in endeavouring to find a remedy, and some degree of success was attained when the orchardists employed certain insecticides, applied by means of the cyclone nozzle, which has been found so useful in this colony. But this was found to be very expensive to spray twice at least every season, and the spraying only killed the insects then upon the trees, and, of course, gave the plants no immunity from attack by fresh hordes bred upon other plants and trees. Another, and a most dangerous remedy (even in the hands of experts), was found to be effectual for a time. The tree to be treated was covered with a gas-proof tent; a portion of cyanide of potassium was placed in a vessel, and sulphuric acid poured on it. This produced a highly poisonous gas, or fume, immediately fatal to all animal life. This plan is universally condemned on account of its dangerous nature.

The success of Mr. Crawford's experiment with the giant coccid put it into the minds of the United States Commissioners for Agriculture to send over a special delegate to Australia, as before said, with instructions additionally to endeavour to forward the parasite of the *Icerya Purchasii* to California. He has already visited New Zealand and New South Wales. In the latter colony he found two or three specimens of the *Monophlebus*, but was not fortunate enough to get the parasite on the *Icerya*. On Wednesday morning, October 3, however, he was shown some orange-trees owned by Mr. John Trewenack, Kent-terrace, Norwood, upon which a few *Icerya* exist, and he was delighted to find no less than nine chrysalides of the fly in the body of the first *Icerya* examined. Two or three more were dissected, and specimens in all stages were found. Mr. Kæbele will at once make arrangements for sending as many specimens to California as can be obtained, and will follow up by fresh consignments in order that by some means the parasite may be introduced to the infected California orange orchards. That the enterprise may prove successful will, we are sure, be the earnest wish of all South Australian colonists.—*Adelaide Observer*.

THE RISE AND POWER OF CAFFEINE.

We have now before us the first fruits of the recent successful application to Government for the right to use "denatured" tea, duty free, for manufacturing purposes, in the form of a very fine specimen of the alkaloid caffeine, prepared, from the material named, during the present month, under the new conditions, says the *British and Colonial Druggist*. The compound is superior in appearance to most of the imported brands, and is in the form of pure, white silky acicular crystals, resembling when in bulk, quinine, and possessing like that principle, though in a less degree, a bitter taste. As the subject of the preparation of caffeine in England from damaged tea, and the consequent probable impetus to the therapeutical use of the alkaloid, have attracted considerable attention recently, both in medical, pharmaceutical, and general circles, we propose to follow our sketch of the agitation, with a summary of the present state of our knowledge as regards the chemistry and therapeutics of caffeine itself.

The alkaloid caffeine, which is identical, chemically and physiologically with theine and with guaranine, is remarkable in containing more nitrogen in its molecule than any other known alkaloid except theobromine, being represented empirically by the formula $C_8H_{10}N_4O_2$. Concerning its constitution—a factor of very considerable theoretical and some practical interest in the case of all such bodies—two theories have been advanced; one by Medicus, in 1875, and the other by Emil Fischer, in 1882. That of the latter investigator accords best with the nature of the decomposition products of the principle, and is graphically exhibited as follows

Caffeine may be prepared from tea by one of at least three processes, viz., (1) by exhausting with boiling water, removing tannin with lead subacetate, and excess of the latter with sulphuretted hydrogen evaporating and crystalizing; (2) by filtering an aqueous decoction, evaporating to a syrup, mixing with slacked lime, and extracting with chloroform; or (3) by evaporating the filtered decoction with oxide of lead, adding carbonate of potassium to the syrupy product, and extracting with alcohol.

The pure alkaloid is only slightly soluble in water (1.35 part in 100 at 60° F.), less in alcohol, and still less in ether (0.044 parts in 100 at 60° F.). It is most soluble in chloroform, a hundred parts of which, at the normal temperature, take up 13 parts of caffeine.

With regard to its physiological properties, Dr. Julius Lehmann carried out a series of experiments and published the results in 1853. He chiefly directed his attention to the influence of the principle upon the functions of the kidneys, which his investigations showed were intensified in a marked degree by the administration of coffee or of caffeine. After a number of tabular statements of the effects of coffee drinking upon the quantity of the urine and the proportion of its constituents, he says:—

The influence upon the organism of daily 4 grain doses caffeine was, save an increased activity of the heart, not observable. Later, therefore, I gave G. M. (one of his provers) 8 grains daily, which induced a more frequent pulse, strong action of the heart, tremors and continual desire to urinate, though only small quantities of urine could be passed. At the same time the imagination was much excited, and subsequently confusion of thought, visions and especially a peculiar intoxication followed, succeeded by a profound sleep.

Lehmann also concluded that caffeine exerted a retarding influence upon tissue change. Gubler, Shapter, Leech and others also proved it to act promptly as a diuretic, simultaneously reducing the pulse rate. Its effects upon this organ are ascribed to a direct action upon the nervous system thereof. In its physiological influence, caffeine seems to resemble alcohol more than any drug, as it directly stimulates the whole nervous, muscular and vascular systems; yet it is a curious phenomenon that it prevents and moderates alcoholic intoxication, so that not only can more wine or spirits, etc., be imbibed, without symptoms of poisoning, if coffee or any liquid containing caffeine be taken with them, but a strong dose of the same alkaloid will entirely avert or moderate an approaching condition of alcoholism.

These results are valuable and noteworthy in that they were obtained by observation of the influence of the principle upon perfectly healthy and robust organisms, and not upon those more or less abnormal from the touch of disease. But from the clinical investigations already made, though not in very great numbers, caffeine would seem destined to play an important part in the relief of suffering and in the saving of life. It has proved an efficient remedy in certain dropsical conditions associated with affections of the heart. Milliken, Brakenridge, Huchard and others relate instances in which it has rescued patients from the jaws of a threatening and imminent death by its direct stimulant effect upon those wonderful ganglia which act as generating cells of nerve force for the supply of motive power to the heart. In atonic dyspepsia, in melancholia, and in other nervous affections associated with the conditions of our much belauded nineteenth century civilization, caffeine has proved a useful remedy, and in it the vast increasing army of those who "coin their brains into gold," often at a rate which the recuperative power of nature vainly strives to compensate,

will find a source of that mental exaltation and intellectual stimulus which are so often required most, when the overstrained faculties are beginning to revivify themselves for long years of unrelaxing tension and of inflexible abuse.—*Oil, Paint and Drug Reporter.*

THE DECCAN VILLAGER AND AGRICULTURE IN INDIA.

Whoever amongst us here—if we except Sir Edward Buck and his intimate disciples—who wants to learn more than he knows at present about Indian ploughs had better read an essay on the subject by Sir George Birdwood in the *Asiatic Review* for October. One must, at all events, be a great deal in the fields and a very close observer of native ways to have picked up all the details with which this article is enriched without being overladen, for it is a long, imaginative and picturesque article—very charming withal in its delightful heterodoxy when it touches any economic problem, and it tells the reader a good deal more about the real life of the Deccan peasant than he will be able to glean from statistical abstracts or progress reports that calculate out his happiness or his misery, as the case may be, to several places of decimals. The essay found an echo at once in the *Times* which published a leader on the 10th October, perfumed, so to speak, with memories of rural Bengal and eloquent concerning the great *Pax Indica*, which careless newspaper readers were so apt to forget while fretted with telegrams about the Black Mountain or Sikkim—mere frothy disturbances on the fringe of the profound calm within. Sir George Birdwood has been inspired to sing the idyll of “The Mahratta plough” by some Pandit of progress who addressed the East India Association a few months ago on the subject of agricultural improvement in India. Sir George scornfully ridicules the idea that the Indian agriculturist can be brought into improved relations with the fields he has cherished through immemorial antiquity by the British manufacturers of steam-digging machinery. He tells the tale of such a piece of machinery brought into one of the Native States in the Bombay Presidency—led out to its work in the black cotton soil wreathed with flowers and scented with *attar* of roses. It snorted and shrieked and moved forward and sank in the yielding earth and foundered there, so that it could neither move forward nor backward. Ultimately it had to be taken to pieces, and the share was painted red and set up in the village as a *lingam* to serve as a symbol of Mahadeo. The real plough of the Mahratta peasant is a piece of apparatus he can buy to begin with for five shillings, and carry home with him when his day's work is done under his arm. Once some native ploughs were photographed for a firm of English agricultural instrument makers that they might see if they could not reproduce them cheaply and undersell the native maker. “It was an evil hope,” says Sir George, “and fortunately there is no chance of its ever being fulfilled.” Soothed by the thoroughly Indian atmosphere of this essay, what reader will fail to sympathise with the writer's feeling, and yet how few of the efforts to improve India by bringing over European manufactures could escape the charge on similar principles of being animated by “evil hopes!” If it is evil to undersell the Indian maker of ploughs, how are we to applaud the underseller of Bombay cottons or Oudh hardware? To undersell your neighbour is the leading enunciation of the great gospel of competition; and only when everybody has beaten everybody else out of the field of industry does the improvement of the commercial enthusiast culminate in the universal prostration which is apparently identical—in economic philosophy—with universal prosperity.

The Mahratta country is described by Sir George Birdwood with affectionate intimacy in all its geographical details, but the picture he gives of the peasant's life is the more truly interesting part of his essay. The scene is so vividly described one cannot help seeing the figures of the Deccan villager—that the writer has imagined so intensely. “The first sound heard after the deep stillness of the night, just before the

dawn, is of the house-father, who having on rising worshipped the family gods, is moving about quietly with his head and shoulders still wrapped in his *chaddar*, rousing up the bullocks and oxen. Then, having got the cattle out and lit his cigarette of tobacco rolled up in a leaf of the *apta* and taken up his breakfast of *jowari* or *bagri* cakes cooked the night before and tied up with an onion or some pickle overnight by his wife, he strolls off at daybreak with his oxen before him to his fields. . .” And then the women's work at home is described, and how they go out to the men in the fields at midday with a dinner of pulse porridge. “The cultivators within hail of each other generally take this meal together. . . so from half an hour to an hour is spent,” and then the men lie down and sleep for a while, and then work again and go home at sunset “in long winding lines towards their respective villages, walking along leisurely, chatting and laughing, and always keeping their oxen before them. Then, tying up the cattle after bathing and again worshipping the household gods, the husband at eight o'clock has his supper of pulse porridge. After this the social life within the village suddenly bursts into its brightest and happiest activity. The temples of the gods are visited, namely, of Mahadeo the great god, meaning Siva, and Bhairava, and incarnation of Siva, and Hanuman. . . In Western, Southern and Central India Hanuman is everywhere the favourite local divinity of the lower agricultural classes, whose innocent gaiety of heart, so promptly responsive to all the pleasanter conditions of their life, he precisely personifies.”

So the description proceeds, and at greater length than will allow of quotation we are told of the various village festivals, and of the appearance and dresses of the women, and of the temple customs, and of the consultations with the astrologer about the right days for sowing the various crops. It all works up to a most timely and admirable peroration directed in scorn at the intermeddlers who prate about “Unhappy India” and get their meagre stock of false conceptions about the country from statistical abstracts and Blue Books. “Unhappy India indeed! I might rather bemoan the unhappiness of England, where faith has no fixed centre of authority; where political factions rage so furiously that men seem to have lost all sense of personal shame, confusing right with wrong and wrong with right, and excusing the vilest treasons against the State on the plea of party necessity.” Bravo! It is rather an unexpected moral to deduce from the study of the Mahratta plough, but good straight hitting none less the less, and further recommended, no doubt, to general consumption by the facility with which everybody in England who reads the passage will applaudively apply it to the people on the other side. But on India, exempt from the feverish torments of the steam-plough, competition, and democracy, we need merely gaze quietly in artistic appreciation. “Happy India! where all men may still possess themselves in natural sufficiency and contentment and freely find their highest joys in the spiritual beliefs, or let it be illusions, which have transformed their trades' union village organisation into a veritable *civitas dei!*” Of course there is an element of æsthetic extravagance in all this, and no subject lends itself more readily to the cruel sneers of the cynic than the idyllic life of the Indian ryot. The dissolving view, as we turn from the one line of treatment to the other, might show us the dinner, so lately enjoyed by a merry group under the shade of a tree—a mockery of hunger with the spectre of famine lurking in some not distant lair. The pretty domestic picture might be stamped by some barbarous customs, and the routine of the house-father's devotions be vitiated by selfishness of rather too sensational an order. We need not override our conviction that anything which has the sanction of native usage is for the best in the best of all possible Maharashtras; and since they didn't know everything even down in *Jalas*, so it is unlikely that they have a complete grasp of all that can be known about the resources of agriculture even in the Deccan steam-ploughs may founder in the black cotton soil, but

on the other hand, a *nangar* would not do much in some other parts of India to extirpate the deeply-rooted grasses that may devastate agricultural area as fatally as the inroad of the sea. We should not be true to our mission in this country if we did not bring over the steam-plough, always supposing we have the moderate commonsense to introduce it only to those of the agriculturists of India who have been defeated by the hard conditions of Nature for the want of such an ally. It is, in truth, refreshing to find civilisation abused sometimes and the innocent simplicity of primitive life extolled by an artist admirer like the author of the essay before us; but that is rather because so much sickening twaddle is always pouring forth from the fountains of conventionality in honour of progress and machinery and competition and free trade, and the other more or less repulsive idols of Western superstition. It is agreeable to hear a totally different note for a change. In their right places civilisation and machinery have their merits, and we should be surprised if even Sir George Birdwood would personally exchange the artificial purlieus of St. James's Park even for a house-father's happiness in a Deccan village, with a double allowance of *holi* festivals and a temple to Hanuman next door. One may most heartily recognise that the Indian ryot is far better off as a human being than the Whitechapel voter—not to speak of his advantages in enjoying a "spiritual faith"—which is not generally laid on in Whitechapel; but at the same time knowledge comes, though wisdom lingers, and if it has come to us of Great Britain first, we are bound to bring it out—even in the shape of steam-ploughs if necessary—to the East, where it is our manifest destiny to do a good deal of ploughing, metaphorically and in all senses of the word. The great blunder that we have to guard against is, of course, the blunder of supposing that *ipso facto* we are doing good when we root up some Indian custom without regard to anything but our own usage and plant a European one in its place. For its value against that sort of thing and against the unholy nonsense of the universal competition creed, with which unhappily the policy of Great Britain is but too generally infected, we may cordially welcome such aching as that of Sir George Birdwood's essay.—*Pioneer*.

SOME OF THE FIBRES OF FIJI.

TO THE EDITOR OF THE FIJI TIMES.

BANANA FIBRE.—The average monthly export of bananas from this Colony has now reached the figure of about 40,000 bunches. As is well known, the trunk of this plant is cut down immediately after the ripe fruit has been gathered; and, up to the present time, no use has been found for it other than a doubtful manure, having a strong tendency to make the soil sour, owing to its moisture-retaining propensities. Added to the 40,000 trunks removed from which marketable bunches have been collected, an additional 3,000 are probably cut down bearing defective and small bunches. Approximately, taking each stem or trunk to produce say three pounds fibrous and cellulose matter, the total paper-making material from this source alone would reach the surprising quantity of 57 tons for the month. I need not dwell upon the benefit the Colony would derive from this article being turned to use, and when it is borne in mind that the cost of production is nil, there appears to me that from this product alone the profits to be derived from the fruit-growing industry could be largely supplemented, and that an article, now wasting, could be turned to good account. A process was patented in England by Berry in 1838, and another by Newton, in 1852, for the manufacture of paper from this fibre. The paper was of excellent quality and of good repute, but the raw materials were difficult to obtain. Several methods by which the water can be removed have been suggested, such as even the common mangle; but as the extent of cultivation and the circumstances of the growers will of necessity vary, I will leave this to the experiment of those interested. *Ai masi* bark, or the bark of

Broussonetia papyrifera, met with particular enquiries. From this bark, the celebrated native cloth, which has attracted much attention to this and adjacent groups, is made; and, in the hands of practical men, the excellency of its fibre is readily discovered. It is said, and with good reason, that its paper-making qualities are better than cotton and perhaps superior to any other material for the manufacture of what is termed vegetable parchment. In fact, even for this purpose it is not used without a mixture of inferior substances. Now, Sir, with our languishing industries, a profitable employment of capital and labor could be found in the growing and exporting of this article; and although I am not at present at liberty to quote the price that may be obtained for it f. o. b. ship in Fiji—suffice it to say that the figure named appeared to me to be remunerative, considering the simple nature of the cultivation of the plant; its rapid growth; its reproductiveness and the facility with which the bark can be gathered independent of the seasons and localities of the group.

Vau bark, or the bark of the *Hibiscus tiliaceus* is another valuable article and can be obtained in large quantities at the mere cost of gathering. Its fibres are highly prized, as being useful for textile fabrics; and it has been manufactured into a high-class paper in other parts of the world, and has supplied the natives of these seas with the material from which their cordage has been made. It grows most luxuriantly on our sea shores as well as in the interior of the islands, and would therefore be accessible to the native population in every district of Fiji. Pine apple leaves, which also form part of the waste of our fruit plantations, should be turned to good account, as the cost of production is nil. The pandanus leaves, and other allied kinds, could be gathered at very little cost and the troublesome weed of the *Sida retusa* could be dried and exported in its woody condition.

As I will require about a ton of dried banana stems, large contributions of this material will be especially acceptable.

Lest the question of freight should be adversely considered by some, I may say to the encouragement of the industry, that Mr. R. could see no difficulty in the way of having a mill erected in this colony at a place where a good supply of water could be obtained and with convenient shipping facilities; but his greatest anxiety was the question as to whether we could supply the quantity of the raw material.

In order to give an insight into the enormous consumption of paper in Australasia, I may mention that Victoria alone imported, in 1886, 7,233 tons, of which 717 tons was classed as writing paper; and this for one colony only!

Can we doubt the extent of a market after this? The manufacturer is ready to meet us and to do his utmost to pay even more than a maximum market price for the material in order to encourage and develop an industry here. Are we to let the chance slip out of our reach?

It behoves my fellow colonists to avail themselves of this opportunity to secure a market for our fibres; remembering that, great ends have always small beginnings. Let them put themselves individually to no more trouble than I have done and I venture confidently to say that success will attend our endeavours.—I am &c.,

W. KOPSEN.

N. B.—To those interested I may say that, for the purpose of comparison, a sample of imported manila fibre can be seen at my office.—W. K.

Suva, 19th Sept. 1888.

TO THE EDITOR OF THE FIJI TIMES.

Sir,—For years past the attention of several of our more energetic planters has been turned towards the practical utilisation of the fibre-producing plants of the Colony.

In a recent issue of your journal the subject is referred to by Mr. Kopsen whose promised information

and suggestions will be anticipated with interest, more especially those which will touch upon "the mere cost of collection."

Up to the present date the most persevering and carefully conducted experiments have unquestionably been made by Mr. Peate of Udu Point, to whom all praise is due. Mr. Robertson, M.L.C., also deserves the thanks of those interested in the increase of our products whether in the natural state, or partly prepared, for having imported one of the latest of Death & Ellwood's fibre machines.

It is, however worth while considering whether the economical and successful treatment of fibre-producing material will not be found to lie in chemical rather than in mechanical processes. To this end the following information may be interesting. Messrs. Christy & Co., of 155 Fenchurch-street, London, E.C., would, upon application, furnish the fullest details upon the subject.—I am &c., F. L. S. Suva, 24th Sept., 1888.

NEW PROCESS FOR OBTAINING FIBRES.

The process consists in heating the plants or fibrous substances under pressure, with a solution of Thio-lyte. The operation may be performed in an iron boiler of any convenient construction, by simply passing live steam direct from the steam generator.

The pressure necessary for obtaining good results depending so much on the nature of the material to be treated and the quality of the product required, it is difficult to give precise information on this point. For the preparation of fibres for textile purposes from fresh green plants, a pressure of from 15 to 30 lb. per square inch will generally be sufficient; whereas if the plant has been allowed to mature, or has become dried, it may be necessary to increase the pressure from 50 to 70 lb., or even in some cases to 80 lb. For the production of pulp for the manufacture of paper, a higher pressure will as a general rule, be required. The boiling process should continue for from 5 to 15, hours, for green plants, according to circumstances, care being taken that the maximum pressure is gradually attained in treating dry vegetable substances. The strength of the solution also depends very largely on the nature of the raw material, and on the amount of substance it may be necessary to dissolve. It should contain from 25 to 33 lb. of Thio-lyte per 100 gallons.

When such plant substances as China grass or jute have been boiled, with a view of obtaining fibres suitable for textile purposes, they should, after being washed, be soaked for about half an hour in a dilute acid (one gallon commercial muriatic acid to 100 gallons of water). This operation must be performed in a vessel constructed of stone or wood, or of some material capable of withstanding the action of the acid.

Since all plant substances either contain bodies of an acid nature or readily yield such on decomposition, it is necessary to prevent the solution from becoming acid during the boiling operation, and Thio-lyte has been specially prepared to this end, thus avoiding the necessity of adding another chemical, such as an alkaline or earthy carbonate.

The following detailed accounts of actual operations will render the principles of the process more clear.—

CHINA GRASS.—5 lb. of desiccated roots, such as is obtained by the "Death Ellwood" machine, were boiled with a solution containing 1 lb. of Thio-lyte (equal to 2 1/2 lb. of crystallized sulphate) in 10 gallons of water, at 60 lb. for 5 hours. The fibre was obtained in a condition adapted to the ordinary process.

The acid Hasep may be treated at any age. When you get it yields no final soft fibre so much desired by spinners. It allowed to keep in the steam it is harsh, and sometimes brittle.

STRAW.—One ton of good straw was boiled for 3 hours at a pressure of 70 to 75 lb. per square inch. Steam was blown in through a horizontal pipe, the boiler being a water tank. A small tank of water was used, containing 5 lbs. of crystallized sulphate, together with 40 lb. steam sulphate, equal to 100 lbs. of Thio-lyte. The straw was perfectly prepared, the most remaining being

WOOD.—The wood should be chopped in pieces of about one half-inch cube, and should if possible be crushed or cut in such a manner as to open out the fibre. Wood (white pine) thus prepared was heated for 12 hours at 150 lb. pressure, with a solution containing 3 1/4 per cent. of the Thio-lyte.

JUTE, ETC.—Jute can be prepared for textile purposes by heating for 10 hours at 50 to 60 lb. with a solution containing 2 1/2 per cent. of the Thio-lyte. For obtaining pulp suitable for making paper, the pressure should be increased to about 100 lb.

ADANSONIA can be very readily pulped at 85 lb. pressure; the other conditions being the same as for jute.

Thio-lyte is found to be very advantageous in the treatment of plants and substances yielding fibre, for it can be used in an iron boiler, or convertor, into which steam may be blown directly. There is, therefore, no change of plant necessary in paper works, and the result is a pulp with a long and soft fibre at a much less cost. By a simple contrivance, the liquor may be recovered and much of it used over again.—Fiji Times.

NOTES ON ESSENTIAL OILS FROM MESSRS. SCHIMMEL'S REPORT.

Angelica Oil.—A parcel of angelica root has been received from Japan, though too recently to allow of a report upon the essential oil distilled from it. Eight species of Angelica are known to occur in Japan, but the exact botanical origin of the present consignment is not yet ascertained.

Arnica Flowers Oil.—It is stated that 100 kilos of fresh arnica flowers yield only about 40 grams of essential oil.

Arnica Root Oil.—In order to afford pharmacists an opportunity of examining this oil more closely, Messrs. Schimmel have distilled a quantity of fresh arnica root and have at their disposal about a kilogram of the pure essential oil, which they are willing to supply at cost price for the purpose of scientific investigation.

Bay Oil.—In respect to this oil, the demand for which is said to be still increasing, Messrs. Schimmel confirm from their experience the statements made recently as to the incorrectness of the description of its specific gravity and solubility, as given in the United States Pharmacopoeia. Oil distilled in their New York factory from imported leaves had a specific gravity of 0.9828 at 15° C.

Betel Leaves Oil.—Samples of this oil have been supplied with a view to experiments being made as to its therapeutic properties.

Calamus Oil.—A sample parcel of calamus roots has been received from Japan, the oil distilled from which will be described in the next report.

Camphor Oil.—The "light camphor oil," being the portion of the crude oil, boiling at about 175° C., is said to be now in regular demand for various technical industries. It readily finds a practical use in the soap manufacture, it having the property of covering the penetrating disagreeable odour of ordinary kerosene or fat and tallow, and also the peculiar odour of bone fat extracted by means of benzene. For this purpose the light camphor oil may be mixed with the fat before or after saponification, about 2 or 3 kilos being required for 100 kilos of soap. It is also said to be used by varnish makers, sometimes alone and sometimes mixed with turpentine. But previous to our opinion was expressed that "light camphor oil" contained camphor, but although it is so called through previous trade usage has not yet been isolated, on the other hand it has been found to contain from 5 to 6 per cent. of camphor crystallized.

It is stated that the essential oil of a small tree, growing in the island of Borneo, yields an oil, as a result of which a very fine perfume has been distilled. The plant is known to be abundant in the provinces of Borneo, Sumatra, and Java, growing along the young jungles.

It will be remembered that in previous reports we have mentioned the discovery of the perfume of the oil distilled from Annona fragrans, the source of most of the essential oils

tus oil received from Australia, but that recently Herr Gildemeister reported that by a more delicate reaction he had obtained that body from amygdalina oil (see before, Sept. 1, p. 164). Referring to this subject, Messrs. Schimmel quote from a published statement by Mr. Staiger, the Brisbane chemist, a passage to the effect that in Australia it frequently happens that in the distillation of eucalyptus oil, the leaves of both species, *E. Globulus* and *E. amygdalina*, are placed in the still, from which is inferred the possibility of considerable variation in commercial oil of *E. amygdalina*. Consequently, the opinion is expressed that the question as to the presence of eucalyptol will not have been definitely settled until an examination has been made of a sample of pure oil specially distilled from *E. amygdalina* leaves, and this investigation the firm proposes to undertake. Messrs. Schimmel state that they themselves have recognized the presence of eucalyptol in commercial amygdalina oil, but that the quantity is too small and the process too difficult to pay for its separation. The "so-called eucalyptol from *E. amygdalina*, which by this time may be looked upon as practically killed," obtained by fractional distillation over caustic potash, is said to consist principally of phellandren, $C_{10}H_{16}$ (eucalypten), and about 20 per cent. of eucalyptol, $C_{10}H_{18}O$. Such a preparation has a specific gravity of 0.890, is strongly laevogyre, and does not solidify in a freezing mixture. It can be easily identified by mixing 1 c. c. of the oil with 2 c. c. of glacial acetic acid, and adding to the mixture 1 to 2 c. c. of a concentrated aqueous solution of sodium nitrite, when a gentle shaking causes almost instant solidification to a crystalline paste of phellandren nitrite. Neither pure eucalyptol nor oil of *E. Globulus* gives this reaction, both remaining unaltered, or at most becoming somewhat darker in colour.

Larger consignments have now been received from Australia of the leaves of *Eucalyptus maculata*, var. *citriodora*, *Backhousia citriodora* and *E. Staigeriana*, which have been distilled. The oil obtained from the leaves of *E. maculata*, var. *citriodora*, is described as corresponding in its characters with the sample mentioned in the April report (see *Pharm. Journ.*, vol. xviii, p. 908). The principal constituent of the oil is a ketone (? aldehyd), which gives with acid sulphites of the alkalis a difficultly soluble compound. It boils under slight decomposition between 205° and 210° C., and is identical with the ketone (aldehyd) occurring in citronelle oil, which according to Kremers has the composition $C_7H_{14}O$, though the analyses made by Messrs. Schimmel correspond more closely to $C_7H_{12}O$. About a kilogram of this body, which it is proposed to call "citronellon," is available for investigation. The oil from the leaves of *Backhousia citriodora* corresponds also with those attributed to it in a previous report (loc. cit.). The aldehyd or ketone-like body there spoken of as its principal constituent has been more closely examined. It has a composition represented by the formula $C_{11}H_{18}O$, boils at 220°-227° C., undergoes decomposition in distillation, and easily resinifies. This body, which has been named "citral," possesses an intense lemon odour and has been found also in small quantity in lemon oil and lemon grass oil, while it constitutes 30 per cent. of oil distilled from "citronelle fruit."

Ginger Oil.—The use of ginger oil is said to show a considerable falling off, the spirituous extract of the rhizome being preferred for liqueurs. The specially prepared ginger from China referred to in a previous report (see vol. xviii, p. 888) has also proved unsuitable and much too dear for the liqueur manufacture.

Kesso Root Oil.—A first consignment of Kesso root, or Japanese valerian root (*Patrinia scabiosifolia*), has been received, and the oil distilled from it is now available.

Lavender Oil.—Messrs. Schimmel criticize some published descriptions of lavender oil and give the following as the character of what they would consider to be a genuine sample. Specific gravity: 0.895 at 15° C., 0.890 at 20° C. Solubility: 1 part in 8 parts of alcohol, sp. gr. 0.864. Distillation: Out of 100 c. c. below 160° C. none passes over; from 185°-190°, 6.5 c. c.; from 190° to 250°, 78.5 c. c.; total below 250° C., 85 c. c.

Cochlearia Oil.—Messrs. Schimmel express the opinion that a genuine distillate of scurvy grass (*Cochlearia Officinalis*) is not to be met with in commerce, and say that it could only be produced at enormous cost, since the fresh herb only contains $\frac{1}{2}$ - $\frac{1}{3}$ per 1000 of essential oil. A mixture of oil of rue with some mustard oil is sold under the name in Germany, which has not the slightest resemblance to the genuine article. Scurvy-grass oil contains as its principal constituent, according to Hofmann, a fraction boiling at 161°-165° C., sp. gr. 0.941, which he has recognized as isobutyl mustard oil and prepared synthetically. Experiments made by Messrs. Schimmel, however, to obtain in this way an artificial scurvy-grass oil have been fruitless, since although the commercial isobutyl sulphocyanate has a certain resemblance to the genuine distillate, it cannot be used as a substitute on account of a highly objectionable odour accompanying it.

Sumbul Oil.—Referring to the difficulty in obtaining supplies of sumbul root for the distillation of this oil, the report states that this drug is not now to be met with in Russia. Formerly it was brought by merchants from Buchara, Turkestan, to the fair at Nischnei-Novgorod, but for some years past, on account of the absence of demand for it, the supply there has ceased.

Rosemary Oil.—The following are given as the characters of an undoubtedly pure Italian oil of rosemary, obtained first hand:—Specific gravity: 0.905 at 15° C., 0.900 at 20° C. Solubility: 1 part in 12 parts of alcohol, sp. gr. 0.864, as a maximum, showing already a trace of turbidity. Distillation: Out of 100 c. c. there passes over up to 170° C., 45 c. c.; from 170°-200° C., 84 c. c.; total up to 200° C., 88.5 c. c.

Mustard Oil.—In correction of some statements that have been made recently as to the amount of sulphuretted oil obtainable from certain cruciferous seeds, Messrs. Schimmel say that the maximum quantity of oil yielded by *Brassica nigra* (Dutch mustard) is 0.90 per cent., and by *Sinapis juncea* (Russian mustard), 0.52 per cent.

Storax Oil.—The residue after the distillation of the oil from *Styrax liquida* is said to be practically odourless.

Wintergreen Oil.—Mention is made that recently samples of wintergreen oil from Java have been received and some doubt is expressed as to its botanical origin. [It may be mentioned that seventeen years ago Dr. Vrij stated in this Journal (vol. ii, p. 503) that probably wintergreen oil could be distilled profitably in Java from the leaves of *Gaultheria punctata*.]

Ylang-Ylang Oil.—According to information received from Manila, the differences in quality of the numerous varieties of this oil met with in commerce depend principally upon the method of preparation and the selection of blossoms, as these possess the finest aroma when freshly picked. In the distillation the first, most volatile, portion of the oil has an incomparably fine perfume, whilst that distilling over afterwards gradually manifests a stale odour; the finest oil is therefore sent out by those firms that distil only the first portion. In practice if 100 kilos of fresh flowers would yield 1200 grams of oil, the finest aroma would be concentrated in the first 600 grams that passed over.

Dilem Leaves Oil.—From Java a sample of "dilem leaves" has been received, possessing a very fine perfume and yielding about 1 per cent. of an ethereal oil that in odour is said to resemble patchouli oil, but to smell essentially fresher, finer, and less musty. It is a yellowish-green, moderately thick liquid, has a specific gravity of 0.960 and boils between 250° and 300° C. It is considered that if the cost of producing this oil should prove to be not too great it might take an important place in perfumery, and steps are therefore being taken to determine the origin of the leaves and obtain a supply.

Massoy Bark Oil.—A large supply of massoy bark having been secured through the agency of the German New Guinea Company, and appeal is made to the patriotism of German perfumers and soap makers to find an application for the first product of this kind from a German colony. The oil is described as

having an agreeable aromatic odour resembling cloves and nutmeg, and as being suitable as a perfume for cheap toilet soaps. The plant from which the bark is derived was discovered by D' Albertis in South New Guinea and named by Peccari *Massoia aromatica*. Grœlin, who attributes the bark to *Cinnamomum Kianis*, Nees, gives in his 'Handbuch' (iv. 356) the constituents of the oil as follows: (1) an almost colourless thin light oil, with an odour of sasafraz; (2) a thick, heavy, less volatile oil, with a weaker odour, but tasting strongly like sasafraz; and (3) massoy camphor, a white powder, heavier than water, less soft to the touch than fatty substances, odourless and almost tasteless, allied to laurin and caryophyllin and soluble in hot alcohol and in ether. In preliminary experiments Messrs. Schimmel have obtained from the bark about 7 per cent. of an oil having a specific gravity of 1.04, boiling between 200° and 300° C., and containing about 75 per cent. of eugenol. The portion of the oil insoluble in soda liquor boiled between 210° and 245° C., and among other bodies contained safrol.

Matsu Oil.—The Japanese oil mentioned under this name in a former report, and supposed to have been a distillate from a birch or beech tar, has now been ascertained to have been derived from a tar of either *Pinus Massoniana* or *P. densiflora*, both of which trees pass under the name "matsu" in Japan. The former is said to show great similarity to *Pinus austriaca* and the latter to *P. sylvestris*.

Citronelle Fruit Oil.—A larger consignment of the small round berries of the size of a pea, designated "citronelle fruit," has been received from Java, and has yielded about 3½ per cent. of essential oil. This oil resembles verbena oil, and is unusually powerful and rich; its specific gravity is 0.980 and it boils from 180° to 245° C. It contains a terpene and citral (see under Eucalyptus oil). In the Indies it is known under the name "minjak serih" and is credited with being a panacea.

East Indian Oils.—Messrs. Schimmel also report upon fifteen samples of essential oil received from India, only one of which was found to be a pure distillate. This was described as "lemon oil" and had a fine lemon and melissa odour, essentially finer than that of citronelle oil, and at a moderate price would probably prove acceptable. The others were all mixtures having a basis of sandal wood oil, and were all condemned as useless.

From St. Domingo samples of oils have been received under the following names:—

Bergamot Oil.—A distilled yellow oil with a powerful and fine aroma, resembling oil of petit grain in odour, but not recalling bergamot oil. Probably the distillate of the leaves and unripe fruit of some species of *Citrus*.

Lavender Oil.—A water-clear essential oil, quite different from the European varieties of lavender oil, and rather recalling spike oil in odour.

Rosmary Oil.—A powerfully aromatic oil, approaching nearer to European lavender oil in odour, and probably utilizable if the cost allows.

Bay or Mountain Laurel Oil.—An essential oil with an odour like that of laurel oil.—*The Journal*.

THE EFFECT OF FIRING ON TEA.

One hears so many complaints about mistakes made over the firing of tea in Ceylon that anything which may add to the knowledge of your planters as to what should be adopted, and what avoided in respect to the practice, cannot but be useful. It is with the object of extending such knowledge that the following extract from *The Times* is sent you. What is therein stated has caused me personally some surprise. Only a week or so back a sample of Ceylon tea was submitted by me to a first-class London firm. It is claimed for this special brand that it is particularly suited to weak digestions, and my own experience with it bears out that claim. But the report made to me was to

the effect that the sample had been so highly fired that it was as the fact specially *unsuited* to persons who suffer dyspeptically. (Is that a coined word of my own?) Now the paragraph extracted says that firing, by decreasing the amount of theine,—“which is said to be to tea what alcohol is to liquors,—decreases the effects of tea-drinking on the nervous system.” It is generally thought that ‘nerves’ and ‘dyspepsia’ are convertible terms. Therefore, why should our authority deprecate firing as injurious in such cases while the Japanese experts recommend it! “When doctors disagree” &c. It must be left to your local preparers to decide for themselves therefore whether firing is judicious or not. Perhaps it is a question of degree only. As to the practice of colouring, it is not quite unusual in Ceylon to adopt it? It has never been stated to me that any of your tea exports have passed through such a process:—

THE EFFECT OF “FIRING” ON TEA.—Certain investigations have lately been made in Japan into the chemical effects on tea of the process called “firing,” which it always undergoes. This is a kind of roasting, the tea being worked by the hands in pans or bowls heated from below. It takes place prior to packing for shipment, and usually under the superintendence of the foreign tea merchant, and is said to be necessary to preserve the tea on the voyage. The process, according to the investigations referred to, diminishes the capacity of the leaf to absorb moisture, the proportion of theine, and the quantity of tannin in solution when warm water is poured on the leaf. The latter is thus rendered less stringent, and on the whole, “firing,” so far from producing deterioration, is pronounced a beneficial process, as it strengthens the aroma, diminishes the astringent quality of the leaf, and, by decreasing the quantity of theine—which is said to be to tea what alcohol is to liquors—decreases the effects of tea-drinking on the nervous system. The colour is also improved in consequence of the employment during “firing” of certain colouring matter. When the latter is a preparation of indigo, it is quite harmless, while Prussian blue is deleterious, and is said not to be used now for the purpose. The consumers insist on having tea with a certain colour on the leaf, and it is solely to please them that the colouring matter is employed. The investigators—two chemists—say that tea is very rarely coloured with any fraudulent intent, and they quote the remarks attributed to a Chinese Minister in Washington to this effect:—“Our producers will give you tea with all the colours in the rainbow if you wish. But why will you drink coloured tea—what is the use of the colour? Reasonable, like us Chinese; we use uncoloured tea, and we know why.” The suggestion in the last sentence, say the chemists, is not correct. Tea is coloured because the consumers will have it so, not because it is of any advantage to the merchant or producer.

—London Cor.

CEYLON'S STAPLE PRODUCTS.

The Ceylon mail received this week brings particulars regarding the exports from the island of its staple products during the commercial year 1887-8, which close on September 30 last. A study of the meaning of these figures reveals some curious facts regarding the place occupied by this fertile island among the raisers of tropical produce. Cinnamon, coconut oil, plantain, tea, and coffee are in bulk the main products of the country, tea being the only one among these which is of recent introduction. Ceylon plantain was first introduced into commerce in 1829 by Mr. Joseph Dixon of the American Crucible Company and the industry created by this gentleman has been for years a source of considerable profit to the revenue of the island, in the shape of export duty. This tax at one time amounted to 2½ per cent. of value, but it has been gradually reduced to its present rate, which, we believe, is 5rs. per ton. But

the diminution of the export duty has not been able to save the Ceylon plumbago industry from decay, and during recent years large numbers of plumbago mines have been abandoned, and the value of the mineral has depreciated to such an extent that 15s. per cwt. will now buy a very fine quality. Nevertheless, the shipments of plumbago from Ceylon during the last two seasons have again shown a considerable increase, and in 1887-88 they reached 254,046 cwts., a total only once exceeded during the last decade. Coffee, once a mainstay of the Ceylon planters, has gone very much out of favour lately, owing, in the first place, to its tremendous fall in price; and from 842,509 cwts. in 1878-9 the shipments have fallen to 136,295 cwts. in 1887-8. The Ceylon people will, no doubt, regret to have participated so slightly in the great speculative movement of the last two years, but still it is scarcely likely that they will again resort to coffee-growing on any increased scale. Many of them have found salvation in tea, and indeed, the soil of the island is generally so well adapted for the cultivation of all kinds of tropical produce that, if tea were to forsake them, the cultivators would have no great difficulty in wooing the favours of whatever new produce might be in the ascendant. Ten years ago Ceylon tea was scarcely more than a curiosity. In 1878-79 81,595 lb. were exported from the island, and since then every succeeding season has outstripped its predecessor by bounds of from 30 to 70 per cent., until in 1886-7 the shipments exceeded 12,000,000 lb., whence they rose in 1887-8 to 20,755,779 lb., or about 10 per cent. of the whole of the tea imports of the United Kingdom. Nearly all the Ceylon tea is sent to the London market, and its average value last year was, roughly speaking, 1s. per lb., nearly 1,000,000l. having thus gone into the pockets of Ceylon planters from this "happy hit." Cocoa is also a new industry—in fact it is, as a commercial venture, even of more recent date than tea, for none was exported until 1879-80, when 122 cwts. were shipped. From that time the imports have increased to 12,611 cwts. last season, representing a value of, say, 50,000l. For this industry there is not so large a scope as for tea, and it is therefore probable that it will not develop to much larger proportions than it has assumed already, although Ceylon cocoa holds a very high rank among the different grades. In connection with these cultivations it may be interesting to state that while the consumption of tea in the United Kingdom increased from 1.22 lb. per head in 1840 to 4.95 lb. in 1887, that of cocoa rose during the same period from 0.08 lb. to 0.43 lb., while that of coffee receded from 1.08 to 0.81 lb. The cultivation of cinnamon is advancing more slowly than that of other staples, having grown from 12,192,208 lbs. in 1878-9 to 1,657,424 lb. last season, in the face of constant retrogressions in price, which are now said to have become so acute as to leave scarcely any profit to the grower. The immense increase of the production of cassia lignea in China and further India and the cheapness of this coarser substitute have probably crippled beyond recovery the Ceylon cinnamon industry, which is known to have flourished in the island from as early a period as the thirteenth century, and was afterwards most assiduously protected by the Dutch colonists. The fruit of the coconut palm, and the products derived from it—copra, poonac, and coconut oil—are shipped from Ceylon in enormous quantities, 385,758 cwt. of oil, which may have been worth about as many sovereigns, and 5,411,572 nuts having been sent abroad last season. The Ceylon product of greatest interest to druggists is of course cinchona. The surprising extension of its cultivation caused by visions of immense profits, the ensuing over-production, the rise of new competition farther east, and the impending decadence of the shipments have been watched and debated anxiously day by day, and many luckless speculators have been laid low by misplaced confidence in the article. Twelve years ago only 16,842 lb. were exported; the season of 1870-80 witnessed shipments pass the million line, in

1883-4 the ten million mark was exceeded; and two seasons later the exports attained the unique figure of 15,364,953 lb. Since then they have been declining, and in 1887-8, as we were able to inform our readers the day after the close of the season, they were smaller than at any time since the close of the 1883-4 season, viz, 11,704,932 lb. What the coming season will bring it is impossible to say, but it seems quite likely that the production from other centres will be large enough to keep prices low, and in that case Ceylon planters will probably withdraw from its culture more and more. Cardamoms are another article of which the shipments have progressed in an extraordinary degree, and in value they now rank second among the minor cultures, the shipments of 310,685 lb. in 1887-8 having probably been worth between 20,000l. and 30,000l., while nine years ago they were so small as not to be worthy of separate record. Nearly half the Ceylon cardamoms are consumed in India and the Far East, the remainder being principally sent to Great Britain, though only a small proportion is actually used in this country. The two other "minor" articles which have risen from unrecorded obscurity since 1880 are oils of cinnamon and citronella. The shipments of both these oils last season are the heaviest on record. Citronella has been exported to the extent of 9,508,157 ozs., worth perhaps 55,000l., against 1,760,677 ozs. in 1880-1, but the price, owing to this superabundant supply, has fallen from about 3½d. to 3¼d. per oz. during the same time, and, if value alone is considered, the shipments in 1880-1 will therefore be found to approach last season's pretty closely. By far the largest part of this citronella oil is consumed in the United States, many of the popular toilet soaps made in that country being scented with it. Of cinnamon oil 144,433 ozs. were shipped from Ceylon last year, mostly to the United Kingdom, but a good deal also to the States. The value of this export cannot very well be determined, as most of the oil is known to consist simply of the low grade distillation product of the leaf, and not of the highly-priced bark oil. Large quantities of cinnamon oil are distilled in Europe from the cinnamon chips, which form a separate Ceylon export article. Among many other notable products of the island are coir and kitool fibres, deer horns, orchella weed, and ebony and Japan woods, but with the exception of the first they are all of minor importance. We should think that the Ceylon planters may find that in future they are more likely to reap profits from the cultivation of a number of comparatively small articles than from a few staples, and among the cultures to which they will probably turn their attention in the first place are cubeba, black pepper, nutmegs, cloves, annatto, vanilla, and other drugs and spices. As the climate of Ceylon is exceptionally suited for the acclimatisation of new products, and only a fraction (it is said less than one-ninth) of the island is at present under cultivation, the future of the ancient Taprubane is altogether beyond calculation.—*Chemist and Druggist*, Nov. 3.

MELONS.—Alphonse Karr owns to a weakness for Melons, but has not yet experienced the fate of Pope Paul, who died one morning after having eaten two large Melons for supper the night before. The Emperor Albert of Austria in 1459, according to the same authority, died from eating too freely of Melon.—*Gardeners' Chronicle*.

INSECT PREVENTIVES.—I notice that on p. 472 of your last issue soot, lime, and Hellebore powder are all recommended for the destruction of caterpillars, but perhaps it is not generally known that gas-tar is a first-rate preventive, which is better than cure. I have had whole plots of Gooseberry bushes devastated by them, and also Cabbage and Cauliflower. Since I commenced to use gas-tar the caterpillars have not made their appearance, and it is both a safe and a cheap remedy for the Gooseberry caterpillar and all others affecting green crops which are subject to attack.—**JOHN MCINTOSH**, Glennachan. [Please say how do you apply gas-tar?—*Ed.*]—*Gardeners' Chronicle*.

CEYLON UPCOUNTRY PLANTING REPORT :

A VARIETY OF ADVICE ON THE PRESENT KEEPING QUALITIES OF THE TEA AS COMPARED WITH THE PAST—AN INGENIOUS MANAGER—THE SUPERIORITY OF LOCAL CIGAR MAKERS OVER TOBACCO PLANTERS—MANUFACTURE OF CIGARS IN COLOMBO—TOBACCO PIONEERS WANTING LONG EXPERIENCE TO STUDY THE FERMENTATION OF THE LEAF—ONE FOR "OLD COLONIST."

11th December, 1888.

I wonder if our teas keep better now than formerly? We have had lots of advice on the matter, and there were those who would have been pleased to have been able to work up a scare on the head of a supposed evanescence of its distinguishing features, and nip in the bud the growth of popular favour, which had set in strongly in the direction of our new product. Public and private advices alike have drawn attention to a non-staying quality; the tea, they tell us, "goes off" after a time. Dealers don't like this, for the public demand, they said was certain to go off too.

Somehow or another we have heard nothing of late of this fatal weakness: whether it is that the market is not depressed enough, and the soul of the planter is not in that state of meek preparedness for being "sat on," which always follows sanctified affliction: or that in the face of the growing deliveries, and other too manifest evidences of a popular liking, to harp on the old string won't do. I don't for a moment fancy we are now perfect tea-makers, or even the class next to that known in Scotland as the "by-ordiner-extraordiner." Yet somehow in spite of a non-staying quality said to be a speciality of the Ceylon tea, it makes its way. But it was not to praise our noble selves that I write. I was rather filled with gratitude towards those, who, when every decent attempt was made to give our product a bad name, stepped boldly forward and told us how to cure it. Too rapid firing, you will remember, was the sum and substance of the accumulated wisdom of our home advisers, the brokers. There was that fellow with the scientific bent, who brought the microscope to bear on the prepared leaf, and found out that the cells in the centre were not so well cooked as the outside, and after that—we were "shut up." We did not feel that we could discuss with a man who had his eye on a microscopic lens on any kind of level terms at all, and let us hope we were content with his ruling, accepted his advice, and fired our teas well. But it is so difficult to hit the golden mean: brokers and tea tasters alone do it, the planter never. If the latter did, the end of the world would have come for the others, and those words of dignified wisdom, which are to be found written in public circulars and private reports, and to which we all look up, would for ever cease. It is well, therefore, that the planter has been imperfectly fashioned, and will ever remain imperfect.

I have a specimen of this imperfection now before me, in the shape of a written howl of indignation against a London broker's report on a late shipment of tea. I won't quote the howl, but when I say that the planter feels that he can only adequately deal with the report in question, after he has had a little time to extend his vocabulary of bad language, he is already a master of Tamil abuse, and knows English Billingsgate fairly well, the state of things may be conceived. The entire offence is that the teas reported on are all said—better quote the original—Dry liquor, too long fired!!! There is a special note at the end recommending the London house to advise their Ceylon friends not to fire their teas so long!!!

The planter wants to make something out of this—say that these teas are specially fired to remedy

the great evil of not keeping &c., &c., but that is too like posing, and "piling the agony." Without any glorification to the planter, or even an acceptance of statement, the thing is complete enough.

The rush of leaf showed too clearly that a new roller must be got. But such machines in these days of sterling quotations mean a lot of rupees, and the estate exchequer could not at the time very well stand the strain. The manager was disheartened; he did not like to come out with a low average, and was sure to for want of rolling power, so being imaginative, and a man of resource he set his brains aworking, and hit at last on an ingenious plan which was to get him the needed machine, without entrenchment on his funds. His suggestion was to advertise in the local papers wanted a "little giant" for his keep! That fellow is sure to get on.

However successful our tobacco planters may yet hope to become, local cigar makers have already made their mark, and it will take a good deal to beat them.

The following is the label on a box of cigars, manufactured in Colombo by a native firm, and which I bought yesterday. The cigars are good:

"Comparison is the true test of quality:

If you want a perfect smoke, try our

No. 1 (Patent.)

A bouquet of roses, a nice leisure hour cigar, mixture of Java, Pondicherry, Dindigal, with Trichy tobacco, dipped in coconut and rose water: fine aroma with the accompanying qualities of real Havanna. Gives the scent of rose after soft smoking. Aids in promoting health. Manufactured by &c. &c."

"A. F." writing from Sumatra the other day holds out a cheering prospect for our tobacco pioneers, when he says that the fermentation of the leaf can only be learned by experience; "but an experience requiring the closest study and attention of at least four or five years." Has "A. F." ever heard of the coconut and rose water treatment? I fancy not; it's a Ceylon dodge. When your correspondent has become what he would call an experienced Sumatra tobacco planter, he will have to trot back to Ceylon for the latest methods, unless he wants to be a learner all his life, he should not wait away too long. Coconut and rose water are not the only things that will be tried here!

A man anxious to turn the honest penny has carefully preserved that copy of the *Observer* in which "Old Colonist" asks for reports on several estates, as to what they are doing on tea. He is ready to supply the reports in question, but wants to know who is to pay him. He is sure that "Old Colonist," when a Visiting Agent, did not do much in the estate reporting way without getting an equivalent in coin, and he would beg to say that although much of the old order has changed, reports that are worth anything have still a market value. I need hardly say that the man referred to is a Scot, and comes from Aberdeen.

PEPPERCORN.

TEA IN AMERICA.

(From the *Indian Planters' Gazette*, Nov. 27th.)

The "Peripatetic Planter" has kindly sent us the following extracts from a letter from an old "Decars" Planter.

New York, Oct. 1888.

"I have been now nearly three months here and am able to give you some idea of the tea trade of America more particularly New York, and as you asked me to write you on the subject, I now do myself the pleasure. Through my brother's influence, I have been introduced

to, and seen a great number of the tea men here. They, one and all, speak highly of the Indian teas as being pure, &c., but confess that the taste of the Americans has been spoilt by Chinas and Japans, and that it would be a long and difficult task to get them to take to Indians, though the brokers believe that they will ultimately find a large sale; but in the meantime, a heavy expenditure would be required, to introduce them prominently before the public. A large staff of agents would be wanted, who would be required to sell the tea at very little, or perhaps no, profit till such time as a demand for the teas was wanted, also a lot of money would be wanted for advertising, which is the great outlet of American enterprise. They also complain that the tea is too strong and pungent for the people's taste; they prefer a nice flavouring tea; they sacrifice the strength for the flavour; they also go very much for appearance, a whole tippy tea fetching them greatly whereas a broken, let it be ever so good, they will not look at. I saw in a broker's office the other day a Pekoe from Dhurmsal, very pretty to look at, tippy and wiry—just what they want here; it was had for 9d.,—19 cents. here. Another great fault they complain of is the unwieldy boxes we send the teas in; they are christened here the Indian Coffins; they are in marked contrast to the neat packages, sent from China and Japan.

"The people here put a great deal of trust in outward appearances, and are much taken by the style in which the Japans are presented for sale. Grocers here sell from the original packages, the customer insisting on seeing that the tea is taken from the chest and weighed in her presence; hence when the purchaser notes the heavy untidy chests that Indians are packed in, as a rule, she concludes that the tea can't be good, otherwise it would have been packed in a better box or chest. What is required for this trade, is neat boxes, containing say 20 lb. or 40 lb., neatly marked, the box well planed and wrapped in gunny or wicker-work, so as to make it of a size and weight easily handled, but on no account should the present heavy maund chest be sent, they are very bitter about the heavy tare they have to pay railways on them.

"In conclusion, I am of opinion that a nice Cachar Pekoe, Souchong or Darjeeling Pekoe Souchong with some style-tippy appearance with flavour, but no strength, packed in neat 20lb. or 40lb. chests should be the tea that ought to be tried first; as the tea gets known, more grades could be introduced.

"I am sending you by newspaper post the *New York Record*, a most influential wine paper here. In it you will find a notice *re* Jas. & Co., Lonchemi, of which firm my brother is junior partner. He has induced me to remain here and I propose going into business in Brooklyn from 1st proximo as wholesale Tea, Coffee, Wine and General Stores. I will be backed up by his firm and have no fear but I will get on, as my Store will be the first of the kind in that district. I have made arrangements for Coffees, Fruits (canned), Wines, &c., and write you in the hope that you will be able to give me some assistance in the tea line. I should be most happy to push Indian teas as much as I could, and amongst the connection that I will have, I should be able to do a large business. Brooklyn especially, where I am located, is principally inhabited by family men, who attend business during the day in New York and return home every evening; they are a very respectable population, and I feel confident that I would be able to do a good thing, as I would be able to sell them direct. I propose confining a portion of the Store for tea sampling, that is where a lady can come in and get several grades of tea brewed for her to taste, and whichever she prefers, she can purchase right away. This plan, I believe, will answer well for introducing Indians, as the people here are very fond of novelty."

PIONEERING AND PLANTING IN BURMA.

I have had rather unforeseen hardships to contend with, viz. in our little Tavoy war. The town was first attacked on the 28th March and saved by the Tavo

Volunteers from destruction by fire and sword, etc. I am Lieut. in command of the detachment of the Moulmein Volunteer Rifles here, and had plenty to do, but did my work with efficiency and received the special thanks of the chief Commissioners, Col. Furlong, Col. Hayter, Col. Plant, and Major Adamson. A few lives were lost on both sides in several encounters with the rebels, and one extra assistant commander killed at Naboola near Tavoy, and a few natives and police and soldiers. Over 45 rebels have been brought in, and 3 have been hanged and the other 11 sentenced to be hanged are now in jail in Tavoy. 14 will be strung up before the end of the month, and some 16 will be transported for life. Some 85 that were caught by the authorities in Siam, near Bangkok, 10 of this number have been identified by Photos sent here, and I fancy the whole number will be given over to be tried here in due course. The hangman in Tavoy is making more money just now than anyone else. 11 men strung up in one day and all at once at R25 per man is a good day's pay. What a time we had until we got reinforcements from Rangoon it would be hard for you to believe. To see all the families, women and children, huddled into the Courthouse and the Courthouse protected by a fort of sandbags to give the Volunteers some protection, and the little plucky band armed to the teeth, ready for them. Night after night, and week after week, we had been on the alert, and it was rather hard when the then chief authority disregarded the rumours until he had ocular demonstration, and then he was "too late," just like the *manny's dog*,—the hare was off. Well, he was sent off himself by the Chief Commissioner, and we had a good man sent down until matters were settled a little, and about 250 soldiers and police with Col. Hayter and Lieut. Rindal, and they went out and fired boldly and in volleys, and wounded thousands of trees, fired 900 rounds and killed no one; but they put the fear of death into them and scattered the enemies and brought in one dead man shot by a Karen Chief and some 26 live rebels, and amongst them one notorious phoongee (Burmese priest), armed with guns, swords, dahs, pistols, revolvers, powder, shot. What a time of anxiety, and your humble servant managed to get one arm broken badly, and the other severely sprained in the beginning of May: thank goodness I am now able to wag my pen again, but this misfortune pulled me down with other worries of different sorts, and nothing for it but a good many kicks behind; certainly not before, for I came off with the thanks in general to Tavoy Volunteers from all the authorities for pluck, efficiency, loyalty, and untiring determination: yes, and we held our own against hundreds. I have no pleasure I can assure in the fighting line, and pray that our weapons of war may be turned into reaping-hooks, and that we may live in peace with mankind, for this gives to the rich more, and to the poor less. Poor people have been in great want this end of the year, living on wild roots, such as wild potatoes yams, bamboo shoots, sprouts of different trees and shrubs, and fish catching. Rice has been as high as R48-0 per basket—a basket is a little less than a bushel measure. I have paid R4 myself for a basket: rice has been sent down by the steamers from Rangoon and Moulmein. The paddy crop this season is A 1; never saw a better crop nowhere, and the poor people this year will be better off if we have the late rains to help the paddy to fill properly. Sugarcane, and Indian corn, and all green crops are first-rate, and the fruit trees are loaded: I have some bending down to mother earth with the weight of crop on the trees; I hope to get a good crop this season of sorts. I am a paddy planter and have 3 acres of paddy, the ears take me over the head, Liberian coffee, annatto, cotton, croton, divi-divi, tea, tea, tea. Fine tea A 1. It would make your hair curl to see my fine tea—aye I and my weeds would make some of you swear, and *ban* Clarendon if he is still to the fore would be in his element, for he would get weeds galore, which is much against my grain. *What can do? Shallie ellia dorie*; must grin and bear it until returns come to hand. Well, I might have gone further and been worse off. I am to make money, that's certain, if the old tabernacle hold together, there's no doubt about that. I am

now well pleased with results, and we must trust to Providence and keep turning round the old wheel. I am sorry to hear of so many deaths of good and true friends of mine in Ceylon; a sad blow to me, people that had a kind and good encouraging word always for me.

JAMES D. WATSON.

THE KELANI VALLEY TEA ASSOCIATION, LIMITED.

Directors:—G. W. Paine, Esq., Chairman; Donald Andrew, Esq., L. F. Davies, Esq., and D. A. C. Scott, Esq.

Report of the Board of Directors, to be presented to the shareholders at their Second Annual Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E. C., on Thursday, the 22nd day of November, 1888, at 2-30 p.m.

The Directors have pleasure in herewith laying before the Shareholders their Report with the Accounts and Balance-sheet for the year ending 30th June 1888.

The opening-up of the Company's property is proceeding satisfactorily, and the tea produced from the old clearing has turned out of excellent quality. The small field has produced for the year 3,814 lb. of tea, giving an average of 424 lb. to the acre. The gross amount realized was £184 18s 9d, which may be considered a very satisfactory result. The acreage now under cultivation consists of:—

9 acres tea in full bearing. (This field on resurvey turned out 9 and not 10 acres as mentioned in last Report):

- 40 acres tea, 21 months old, coming into bearing.
- 15 " " 15 " "
- 220 " " 12 " "
- 216 " " cleared and being planted this year.

The weather during the past year has been abnormally dry, and the growth of the plants on the last division has been somewhat delayed, but, from recent advices, we learn that rains have been abundant, and that the newly-planted fields are now making satisfactory progress.

The Directors authorized the purchase from Government of a small block of land (20 acres) adjoining their property, which, they were advised by their Manager, it was in the interests of the Company to acquire, and this purchase has been effected. In reference to the Accounts, the Directors have departed from the very usual course in Tea Companies of debiting all charges to the Estate Development Account until the gardens come into bearing, preferring to keep the Capital expenditure as low as possible. The item "Directors' Fees" although appearing as a charge against Profit and Loss, has not been drawn, nor do the directors propose taking these fees until such time as profits are earned. Of the £2,250 authorized issue of Debentures, Bonds for £2,450 have been placed, and applicants for the balance are available when the money is required. The Directors consider the future prospects of the Company so favourable, they propose further developing the estate and erecting permanent buildings, machinery, &c. To do this efficiently, a further issue of capital may shortly become necessary. Mr. Herbert L. M. Davies, the Company's Auditor, retires in accordance with the Articles of Association, and, being eligible, offers himself for re-election.

G. W. PAINE, Chairman.

16, Philpot Lane, London, E.C., 10th Nov. 1888.

THE PROFITS OF THE MILL INDUSTRY IN BOMBAY.

(FROM A CORRESPONDENT.)

The Manchester manufacturers were lately engaged in emulating the discussion of the Big-Endians and the Little-Endians of Swift, and they are not yet sure whether they are losing an important section of their trade by fluctuating exchange or declining freights or the long working hours of the Bombay operatives. To them the following tables will doubtless supply food for reflection, and it is to be hoped that such reflection may induce on their part sobriety in the treatment of a problem, the right solution of which concerns their interests so vitally. The tables in question contain a summary of the accounts of the Bombay cotton mills for one whole year, such year ending in some cases with December, 1887, and in others with June, 1888. For obvious reasons, we have included only those mills which are in regular working order, and which publish their accounts for their shareholders. Some of them make up their accounts half-yearly, and in that case we have had to set out their figures to us to show their operations for one whole year. The mills are also divided into groups according to the nationality of their managers, for, as we shall show further on, the working and condition

and even the nomenclature of the concerns depend not a little upon the idiosyncracies of the respective nationalities. The first group is denominated English, as the mills comprised therein are managed by English firms, one of them having the management of five of the following seven concerns. The accounts given are for the year ending June, 1888, except when otherwise mentioned.

(a) N.B.—In the Petit Mills the interest item is mixed up with brokerage and exchange.

Business men will draw their own conclusions from these several figures. We are only concerned here in elucidating some of the points requiring explanation. For example, mill No. 1, the Anglo-Indian, charges no commission. This mill is an Anglo-Indian concern in reality as well as in name, its capital being partly subscribed in England and partly in India, and its accounts are rendered in rupees, as well as in sterling money. Its directorate is in Manchester, and it is managed here by a paid staff; hence no commission. But its accounts show the working of a law of compensation. For, whereas its mill and office establishments, including directors' and committees' fees, amount to R1,38,224, a mill of about the same size in the group and with nearly the same capital—the Empress (No. 3)—is managed at a cost of only R1,23,781 in these several items, and has paid besides R12,291 for commission to its agents. We have not given the block account of the several mills in the table, but its total cost for this group, including machinery, buildings, and land, amounts to 58 lakhs in round numbers. The difference between this item, and

the amount of the paid-up capital, say, 41 lakhs, is 17 lakhs, so that out of 31 and odd lakhs of loan capital only, about 14 lakhs represents the working capital. This amount of borrowed capital, together with 5 lakhs of reserve, enabled the mills to earn R9,07,777 of profit, or equal to nearly 23 per cent on the paid-up capital, and that after paying interest at 5½ per cent. on the borrowed money. No wonder, then, that they find it to their advantage to deal with "other people's money," taking the risk of carrying a heavy lien on their heads. So long as money is cheap and times are smooth, such a course is plain sailing, but when times change the lien is sure to press with a double weight. In this view it is fortunate that the mills, instead of dividing the whole of the profits of over nine lakhs, carry the greater portion to increase their reserves, to provide for their wear and tear, and to make other provisions for strengthening their financial position. The earnings of the Connaught Mill (No. 2), it will be seen, are close upon 40 per cent, but its block account is over ten lakhs against a paid-up capital of only 4.15th lakh, so that it is obliged to use over nine lakhs of "other people's money." This is rather a risky position for times of financial pressure, and it is therefore a relief when we find it keeping three-fourths of its earnings as at stand-by, distributing one-fourth amongst the shareholders.

The next group we give is the Parsee group, and it comprises nine mills, of which four (Nos. 3, 7, 8, 9) may be described as old concerns. Their accounts, too, are given as on 30th June, 1888, except when otherwise indicated.

Financially this group shows to better advantage than the English group. Its paid-up capital is 130½ lakhs, in round numbers, against a block account of 156 lakhs, but as the mills can fall back upon a reserve of over 23½ lakhs they have no lien on them in that respect, as is the case with the English group. The loan capital of this group is about 43 per cent of its own money, though it has had to pay interest on the amount at 7½ per cent against 5½ per cent of the English group. Looking to the earning columns, it will be found that, like the English group, those mills which have a larger block account than their capital, and whose borrowings consequently are greater, show a better result than their neighbours. These mills are Nos. 1, 2, 4, 5, and 6, whose earning range between 18 and 22½ per cent. They are all new mills, they have a block account of 43 lakhs against a paid-up capital of only 28 lakhs. No wonder, then, that when they can earn over 20 per cent, with borrowed money, which costs them much less, they should like to sail with light ballast, though it is necessary to remind them of the prudence of not forgetting the Ides of March. The item of commission in this group offers a marked contrast to the same item in the English group. The gross earnings of the mills are comprised in columns 9 and 10 of the respective groups, and we thus find that, while the English mills pay their managers only R64,420, out of R9,72,197, the mills have paid R5,61,001, out of R23,57,297, being equal to 6½ and 22½ per cent, respectively, on the gross earnings. The system of

charging commission in our mill management is a threadbare subject of controversy in these parts, and it is scarcely necessary to say that most of the mills in Bombay allow their managers a quarter anna per lb. upon the yarn sold, which, for rough calculation, may be taken at 3½ per cent on the gross proceeds. The English mills, however, allow only 10 per cent on the net earnings, and the newer mills that are now being projected are obliged to conform to that system or to a sliding scale in which the remuneration bears some relation to profit. The Jamshed Mill, in the Parsee group, sets a laudable example in the former respect, as its commission is a percentage on the net proceeds only. It will be seen that financially the Maneckjee Petit Mill is the strongest, having a reserve of fully 35 per cent of its capital, and this tells favourably on its earnings, which are the highest but one of the old mills in the groups that precede, and that which follows.

The group which follows is the Hindoo group, which comprises mostly old mills, only three mills (Nos. 2, 6, and 13) being new concerns. Another speciality of this group is that the mills combine spinning and weaving, whereas the majority of the two previous groups confine themselves to spinning. This is probably owing to the business relations of the managing firms with the interior parts of the country, which enable them to move off their cloth to better advantage than their English or Parsee neighbours. The accounts of this group also are made up for the year ending June, 1888, except when otherwise mentioned

				1,23,10,500	63,69,458	24,27,730	3,48,930	5,73,109	15,37,679	16.63	10.50	
				Average percentage of earnings and dividends.....						12.61	8.68	
1	Sussoon (1887)	1,200	918	15,00,000	10,33,435	1,62,716	1,99,220	60,135	4,92,238	19.50	10	

It will be seen that this group runs parallel with the Parsee group, not only in regard to its paid-up capital, but also in respect of its reserve funds. But when we come to look at the block accounts, then they part company, the Parsee block account being 156 lakhs, against 164 lakhs, recorded by the Hindoo group. In regard to the rate of interest, also the Hindoo group, advantage over the Parsees. The latter have paid 7½ per cent. for their money, whereas the Hindoos have been able to get theirs at 5½ per cent only. Their earnings, however, show only 12.61 per cent, against 16.62 per cent of the Parsees, and the difference can only be accounted for by the large number of old mills in this group, as well as by so many of them having a weaving business, too, which seems to be a drain on the spinning department. It will further be seen that like the Maneckjee Petit in the Parsee group, Morarjee Mill (No. 9) is financially in a strong position, and for the same reason, namely, owing to its having built up a good reserve (R7,17,480) which amounts to 65 per cent. of its capital. The dividend paid by this mill (14½ per cent) is the highest of any of the old mills in all the groups—though the Indian Manufacturing (No. 6) runs close to it, with its 11 per cent. In the interest of pro-

dent management, however, one could not help wishing that the last mentioned concern had looked closely to its reserve, which is only ten per cent of its capital, against 65 per cent held by its rival, though in this respect its action is quite justifiable when contrasted with that of one of the English mills. This mill, in order to round off a half-yearly dividend, had to borrow money, and the amount so borrowed appears in its accounts as "loss" on the half-year's operations. The last mill on our list is the Sussoon's, and though moving in an orbit of its own, it has nothing to learn from its rivals. On the contrary, for an old mill its percentage of earning is the highest of all but one of similar concerns, and instead of dividing the whole earnings, the managers have, with real mercantile instinct, taken a moiety to increase their reserve, and otherwise strengthen their position.

Taking then all the groups together, the main result is that with a capital of three crores and fifteen lakhs, or 33,500,000 conventional sterling, the cotton industry here has realized a gross return of R18 lakhs, or 1.80,000, or over eighteen per cent. Some three years ago it was mentioned in *The Economist* in an article entitled "Scottish Capital Abroad" that more than twelve million of Scotland's money invested in America and on the continent had not returned

a cent of profit for many years together. Need we point out, after such an experience as theirs, and in view of the fact vouched for by the figures given above, what home capitalists ought to do? To those disposed to act upon the inference, the interior of India offers an almost uncultivated field. What the prospects of that field are, are vouched for by the published accounts of the Central India Cotton Manufacturing Company. This mill, working in the very heart of the cotton districts, and with a capital of 18½ lakhs, has earned, for the year ending June, 1888, a gross return of Rs72,155, equal to 30 per cent., and that after paying over Rs91,000 for interest no its borrowed capital of 12½ lakhs, a result which is hardly approached by any of the mills working in overcrowded Bombay.—*Bombay Gazette.*

DRUG TRADE REPORT.

LONDON, November 22nd.

CINCHONA.—The fortnightly auctions held on Tuesday were the smallest in extent held for some time, although the average standard of the bark, owing to the large proportion of South American Calisaya quills, was a high one. The catalogues comprised:

	Packages	Packages	
Ceylon bark ...	960	of which	712 were sold
East Indian bark ...	344	"	224 "
Java bark ...	341	"	275 "
South American bark	1,071	"	551 "
Jamaica bark ...	87	"	87 "
Total ...	2,803	"	1,849 "

The auctions commenced with a fairly satisfactory tone, but competition very soon fell off, and dullness reigned supreme until the end of the sale, many holders preferring to buy in the bulk of their supplies rather than to accept the low prices offered. Of two small catalogues not one single lot was sold. It is generally said that the prices show no material alteration on those of the previous auction, but we should be inclined to place the unit not higher than 2d. The following are the approximate quantities of bark purchased by the various buyers at the auctions:

	Lb.
Agents for the Mannheim and Amsterdam works	86,149
" the American and French works	79,161
" the Auerbach works	55,391
" the Brunswick works	39,826
" Messrs. Jobst & Zimmer	25,412
Messrs. Howards & Sons	14,315
Mr. Thos. Whiffen	14,110
Sundry buyers	12,350
Total quantity sold	326,714
Bought in or withdrawn	171,936
Total offered	498,650

EAST INDIAN BARK.—Succirubra: Original quill and chips 3½d to 4d; renewed shavings 4½d to 9d per lb. Crown: Shavings and chips 4d to 9½d per lb.

JAVA BARK.—Ledgeriana: Root 6½d to 8d; dusty branch quill 6½d to 7½d; dusty to fine chips 5d to 10d; stout fine rich quill 1s 4d; 1 bale fine chips 1s 5d per lb., the highest prices paid at the auctions. Succirubra: Broken dull sea-damaged to thin but very bold long quill 3½d to 6d per lb.

JAMAICA BARK.—Crown: Low branchy chips 2½d to 3d; weak broken quill 4½d to 5½d per lb. The shipments from Ceylon since the opening of the new season on October 1st have reached proportions very much in excess of what had been expected. This is partly owing, no doubt, to the fact that in the latter part of September freights were very scarce at Colombo, and the arrivals from the plantations accumulated at that port until more ships were available in Oct.

SOUTH AMERICAN BARK.—More than half the quantity offered consisted of Bolivian cultivated Calisaya, which sold very freely at comparatively good prices, up to 1s and 1s 1d per lb. for fine bold silvery but broken and slightly sea-damaged quill; 10½d to 11d for good stout quill (10d for the damages); and 8d to 9½d

for fairly good ditto. Nearly all the Cuprea bark offered was bought in, a few parcels selling at 3½d to 4d per lb. Two or three of the parcels have just been imported, for one of these 3½d is asked, while another is held at 3½d per lb. for the whole "pile." Other lots, of old import—1882 and 1883—are held by the importers at the recent auction rates, which were not obtainable yesterday. For two parcels of Soft Columbian character, import in 1880-81, very dusty 2½d to 3d per lb. was refused. For some hard Pitayo (1882 import) 4½d per lb. is named.

CUBEBS.—Good genuine berries are still quoted at £26 to £27 per cwt., but we do not hear of business. The cultivation of cubebs is to be commenced in British North Borneo by a Java planter, who has asked, for a concession of 4,000 acres on the Bengkoka River for the purpose of cultivating Liberia coffee, Ceará rubber, and cubebs.

QUININE.—Another penny decline on German brands has been an event of the week. The market last Friday closed dull at 1s 4½d per oz. on the spot, and 1s 5d forward; but on Tuesday, after the bark auctions, second-hand sales were reported at 1s 4d, and subsequently at 1s 3½d to 1s 3¼d for second-hand lots on the spot. The market closes weak at the latter prices, though another little spurt of life next week, or even this, would not much surprise us. Makers' quotations remain unchanged.—*Chemist and Druggist.*

BURMAH A RICE GROWING COUNTRY.

There is probably no country in the world where the production of rice for exportation can be carried on so successfully as in Burmah at present. Many other countries in the far east can produce rice in abundance, but where the population is very dense the rice produced is required for internal consumption; and where facilities for cheap transport to the coast do not exist, there is no use in producing any surplus rice. In Burma, we have an eminently suitable soil and climate, and every natural facility for cheap carriage, the population is very far from being so dense as to eat up all the rice produced. On the contrary one of our drawbacks is that our population is not numerous enough to bring the available land under cultivation. With these advantages there is no immediate danger of our losing our rice trade at present; but it would be a mistake to reckon too confidently on retaining our present advantages for any indefinite length of time, or to ignore the efforts other nations are making to get into the rice trade.

Our French neighbours are very anxious to obtain a larger share of the trade than they have now, and they eagerly watch every chance of obtaining this end. Quite recently they have discovered that the transit duty of five cents per picul, which for the last three years has been levied on rice and paddy of Siamese origin descending to Saigon and Cholon by the Mee-kong across Cambodia, has pressed so heavily on the trade that the exportation of this kind of rice has practically ceased. This has been pointed out in a report by M. de Champeaux, Resident General of France in Cambodia and on the strength of this report M. Richaud, the Governor General has published a decree in the *Journal Officiel* of Cochin-China, suppressing the transit duty. At the same time the river "Messageries" have lowered their freights, so that every facility possible is now afforded for the bringing down of Siam grown rice to Saigon and Cholon, and the merchants there are looking forward to a greatly increased trade.

Rice is an article for which the demand is not at all likely to decrease in any way. On the contrary it is the staple food of a very large portion of the human race; it is cheap and nutritious, and even as a food it seems to be coming in a very general use in many countries. It is also used for very many purposes besides food, and apparently there is no limit almost to the quantity which can be absorbed. There is ample room for Saigon to increase her exports without materially reducing those from the Burmah ports, but if everything possible is done to make the rice exported from Saigon cheap, and if the other

rice-growing countries of the world very materially increase their production and exportation during the next few years; there must be a further fall in the value of rice. Should this occur Burmah rice will not bear the heavy land tax and the export duty now put upon it. As competition in the trade becomes keener, the Burmese paddy grower will have to work more economically than he does now, he will find that to make his paddy field support himself and his family he must buckle to work in earnest and not employ coolies so much as he does now; and Government will also find that it also must reduce its exactions on rice.

When one comes to think over the matter it is a most marvellous thing that the production of a simple and formerly somewhat despised grain should have done so much for any country as rice has done for Burmah. Thirty-five years ago had any one foretold that the wretched swamps which the East India Company had been compelled to annex would prove the source of wealth they actually have done both to the people and to the government he would have been regarded as a lunatic. It is not too much to say that free and unfettered rice cultivation has made Burmah. What the country has derived from other sources is altogether insignificant in comparison. But the very facility with which this wealth has been acquired tends to give both Government, officials and the actual cultivators erroneous impressions of what they can get out of rice. The danger is not very imminent, perhaps, but other nations are becoming alive to the fact that rice fields may be turned into a source of great wealth and they are learning to turn them to account. Burmah was practically first in the field, and has had something approaching to a monopoly of the trade for many years, but sooner or later she must face a more active competition than any she has yet encountered; and it is to be hoped that all concerned will be wise in time and make the necessary reductions in the cost of rice before any check has been put on the export of Burmah rice, by the increasing quantities of cheaper rice from elsewhere thrown on to the great markets of the world.—*Rangoon Gazette.*

THE MINERVA FRUIT EVAPORATING AND PRESERVING COMPANY.

Recently, a representative of this journal paid a visit to the Evaporating Factory in Levuka of the Minerva Company, with the object of ascertaining the special merits of the particular type of evaporator in use there and of judging, as far as possible, of its general capability to suit immediate and probable future requirements in Fiji. It is plain that an industry of very great importance to this colony is being initiated by means of the principle of evaporation or desiccation, and that the use of this principle will make all the difference between highly profitable productions and the reverse. Banana growers have long felt the want of some means of dealing with the large surplus of their fruit, which, for various reasons, is not available for shipment while green, and which consequently is wasted in large quantities. In evaporation they certainly have the remedy at hand. Our representative was shown samples of this fruit prepared by the American Evaporator, which is the machine in use at the Minerva Co.'s establishment. In taste and appearance nothing is left to desire, and the price (4d per lb.) at which the prepared article is sold wholesale, leaves a very handsome profit in operation on what would otherwise go to waste, or nearly, at least, to feed cattle. The evaporator seems to be a great improvement on the sun-dried article, and that export fruit is highly appreciated by the American public, if any doubt can be formed from the number of orders coming from the neighbouring colonies; but, beyond this, in culinary and confectionery uses it is found to be equally possible to tell it from the more expensive rusin.

The Minerva Company at present pack their bananas in 7 1/2 lb. tins, hermetically sealed, at a

cost of about 1/4d per lb., thus securing perfect preservation at a low cost for packing. Our representative was shown samples of desiccated coconut and confectioner's copra made by the Company; which for whiteness, sweetness and perfect preservation and appearance would be impossible to be beaten. The great advantage of the principle applied is that the heat is utilized direct instead of through any intermediate or accessory agency. The fuel burnt generates the largest possible amount of hot dry air, which comes into immediate and automatic contact with the substance to be dried, and the machine is so arranged that an enormous drying surface is available for evaporating by this air. The output of finish product is in proportion, while the labor and fuel required is small. The heat is perfectly under control, and any degree up to 400° Fah. can be quickly obtained. With regard to the extension of the uses of this machine and principle, upon other products than those shown our representative, space forbids our doing more than merely glancing at the wide and profitable variety of its uses in a tropical country. If coffee planting should be revived, it would give a new and greatly increased value to that product, as it has been found to turn out an article in flavour and quality infinitely superior to the crude method of pulping sometimes resorted to here. Similar advantages result in tea and cocoa drying, and the "American" as applied to tea preparation in the Wainunu district is reported a distinct success, and will certainly procure for its user appreciative demand for his growth and make.

Another immediately prospective use of the machine is in desiccating pineapples. About one cwt. of these, prepared by the "American," were sent to the colonies last season as a sample; with the result that they elicited the very highest commendation on their merits, by comparison with other makes now getting known in Australia. A further result is the offer of orders thence at 1s. per pound; a price at which a fortune could be made, and which should stimulate the growth of this easily cultivated fruit on a large area in Fiji.

We shall be glad to refer again to the subject of evaporating as its uses in various ways become developed or the subject of actual experiment in this colony.—*Fiji Times.*

[We suggested the preservation of plantains in Ceylon by means of the American Evaporator, and we do not see why it should not pay.—Ed.]

CEYLON TEA AT THE MELBOURNE EXHIBITION.

13th December 1888.

The Editor "Ceylon Observer."

Sir,—I beg to annex extract from the *Age* Supplement, dated 13th November 1888, as it gives some interesting information regarding the "Ceylon Tea Room" at the Melbourne Centennial Exhibition.—Yours faithfully, A. PHILIP, Secretary.

(Extract from the "Age" Supplement.)
MELBOURNE CENTENNIAL EXHIBITION.

Melbourne, Tuesday, Nov. 13th, 1888.

FREE OFFERINGS.—A visitor from one of the neighbouring colonies observed that the hospitality displayed at the Centennial Exhibition was very remarkable. It was not as a distinguished guest at the weekly luncheon of the President of the Executive Council, nor as a friend, but as a stranger. A turn of inspection round the building had resulted in a resolution to take two or three boxes of Attention tea, a cup of Van Houten's cocoa, a basin of soup, bread or other things of such a kind of mustard, cold meat, and a sample of tea, and eat and drink. These are all, of course, excellent and good. At the same time offered are of excellent quality. A cup of Van Houten's cocoa testifies to the difference existing between entirely pure articles, and the many inferior qualities that are to be met with. Messrs. Atcherley

and Dawson, tea merchants, invite visitors in the most cordial manner to visit their tea sampling and reception rooms in one of the minor courts, where excellent tea is served in the afternoon and evening. The stand erected by the Tea Planters' Association of Ceylon is unique in its character and the place is thronged all the afternoon with persons anxious to avail themselves of the open invitation given. It is novel to many of the visitors to be waited upon by two natives, one a Sinhalese, the other a Tamil from the southern portion of Hindustan. But the great novelty is in the tea itself. The clear amber fluid dispensed is so different to the highly favoured, mixed and manufactured teas of commerce, that the majority of people at their first visit vote it peculiar rather than attractive in flavour. But there is some fascination about it, for a second trial he gets a desire for a third and many visitors eventually order cases, protesting that they cannot drink the ordinary tea again. The Ceylon tea resembles a little the Japanese variety which is drunk throughout the United States, but more in colour and freedom from adulteration than in actual aroma. To a young country like Australia it is highly encouraging to see in how few years comparatively an immense trade can grow up by means of a staple production. In 1877 the exports of tea from Ceylon were 1775 lb. The estimated crop for 1889 is 32,000,000 lb. Ceylon contains a little over 15,000,000 acres of land altogether. At present only 3,000,000 acres out of, say, 12,000,000 available are under cultivation. When we compare the size of Victoria, with its 87,884 square miles of territory, and the Australian Continent, which gives a total of 2,944,828 square miles, we can fairly gauge the possibilities of the various industries that are being established throughout the land. Irrigation, combined with scientific methods of cultivation and the genial Australian climate, should give results which at present can scarcely enter into the dreams of the most sanguine.

SYLHET ORANGES.—We had the pleasure of receiving today a very acceptable parcel of Sylhet Oranges from Dr. Stork, grown on his property at Heneratgoda, Comillah estate. They are very like mandarins, but larger and with a distinct flavour, and should prove a welcome addition to Ceylon grown fruit.—Local "Examiner," Dec. 6th.

TROPICAL FRUITS.—The Division of Pomology of the United States Department of Agriculture has published a report of the tropical and semi-tropical fruits grown in the Southern States. The report has been prepared by Mr. H. S. van Deman, chief of the Pomological Department. The several fruits are enumerated, and details given as to their culture, and the insects and diseases to which they are subjected.—*Gardeners' Chronicle*.

THE VINE.—A French vigneron, M. Chatin, has just communicated to the Academy of Sciences the result of some very remarkable experiences with the phylloxera. He has a well-known vineyard at Meyzieux Isère, which has been preserved all through these long phylloxera-visited years of sunny France—like an oasis in a desert—not only from phylloxera, but mildew, black-rot, *et hoc genus omne* altogether. He ascribes his protection to his particular treatment of the manures for the soils of his vineyard. He has all along treated them to the following manures:—First, he has a systematic process of nipping; then he applies a strong manure, which includes granulated phosphorus and products, with a base of potash, nitrogen, lime, &c. The real facts of the case are that vines are highly-civilized plants. They live freely and yield freely. You can no more hope to get good and perpetually good crops of grapes without feeding the plant well, than you could get good speeches from your own Parliament unless the speakers had well dined and—liquored.—*Dr. Taylor in the "Australasian."*

CINCHONA BARK FROM JAMAICA.—A somewhat unusual feature at Tuesday's cinchona auctions was the sale of 87 bags of cinchona from the Jamaica plantations. The bags were rather light (the whole parcel weighed only 5,936 lbs.), and they were the proceeds of the importations from what island during the last three months. As during the whole of 1887 the shipments of cinchona from Jamaica reached 17,009 lb., we need not anticipate any alarming competition from that quarter just yet. In appearance the Jamaica bark sold yesterday was decidedly inferior, the twigs which seemed to belong to the *Crown* variety, being weak, broken, and apparently the produce of young or sickly trees. The alkaloidal value of the our parcels is given as follows:—

Quinine sulphate	Total alkaloid
per cent.	
39 bags, selling at 5½d. per lb. = 283	454
12 " " 5d. " = 247	358
25 " " 4½d. " = 358	197
11 " " 2½d. to 3d. " = 137	212

—*Chemist and Druggist*, Nov. 24th.

THE RETAIL PRICE OF TEA IN GERMANY.—The *Deutsche Handels-Archiv*, the official commercial publication of Germany, in its last issue discusses the reasons for the small consumption of tea in that country, and comes to the conclusion that the enormous retail price is the main cause. It thinks that the spread of tea-drinking in the country is greatly to be desired, but this is impossible as long as the retail dealers persevere in charging the present excessive prices. It instances the establishments in the West-end of London where the average price for tea of medium quality is 1s. 6d. per pound, including the heavy English duty of 6d. per pound, and the finer sorts may be obtained at 2s.; while in Germany the retail prices begin at 3s. a pound for the poorest qualities, and go up to 9s. For German retail dealers it would seem that the large and universal fall in the prices of tea in the last twenty years has never existed; yet in England the tea that was 2s. 6d. a pound in 1866 was 2s. 1½d. in 1876, and is now 1s. 6d. a pound.—*L. & C. Express*.

THE RICE TRADE OF INDIA as affected by the export duty is thus dealt with by Lord Cross in a despatch to the Indian Government:—

	RICE,		
	Quantity Exported. Cwt.	Value of Exports. Rxs.	Duty Received. Rxs.
1881-82	28,888,421	8,308,167	762,268
1882-83	31,258,288	8,476,327	832,312
1883-84	27,040,330	8,363,280	719,068
1884-85	22,051,532	7,192,197	588,394
1885-86	28,222,595	9,247,126	743,849
1886-87	26,879,272	8,836,827	708,422

"Nor can it be assumed that it will be possible to maintain all the existing sources of revenue. The question of the duty now levied on the export of rice will continue to be a subject for discussion. The economical objections to it have always been evident; but it was held that the duty was rendered less injurious by the fact that India and Burma possessed an almost complete monopoly of the supply of rice to Europe. Mr. O'Connor refers, in the 97th paragraph of his Review of the Trade of India in 1886-87, to the stagnation of the rice trade; and, in the 30th paragraph, he remarks that it has 'much to contend with since the fall in price of all the other material used for distillation and starch, such as potatoes, rye, barley, maize; even wheat has been used for the manufacture of starch, so low has the price fallen.' There has been no increase in the exports of rice since 1881-82, and in those from Bengal especially there seems to have been a marked reduction; and the amount collected as duty thereon shews a tendency to diminish. This is a subject which will no doubt receive the attention of your Government."

CEYLON TEA IN AMERICA.

We call attention to the long and interesting letters (see page 477) addressed to us by Mr. J. L. Shand and Mr. McCombie Murray, to which we have no doubt the Tea Fund Committee especially will give due consideration. Mr. Shand writes forcibly and to the point as he generally does, and Mr. Murray clearly shows that he is maintaining a gallant struggle in the interests of Ceylon tea and that he is deserving of encouragement. But we cannot help expressing our surprise that there is not a word in the whole of his long letter about the pre-eminent importance of carrying his teas to the consumers in that part of America—namely the Central and Western States—where, in our opinion, there is far and away the best chance of creating very rapidly, a steady and ever-growing demand for our Ceylon teas. We know Mr. George W. Childs—at least so far as a very pleasant, interesting interview in his princely editorial sanctum could make us acquainted—and esteem him as perhaps the most notable and high-principled of American journalists, and his paper is undoubtedly a power in every sense, in the fair state of Pennsylvania and also considerably beyond its bounds in the Eastern States. But we very much question whether Mr. Childs himself would not agree that it would be wiser, as a beginning at least, to carry a new product like Ceylon tea—as also its advertising,—“out West,” to Chicago, to Kansas City, Omaha, Denver and even Salt Lake City, than to begin knocking against the prejudices due to a hundred years’ building-up of the Americans in the old and settled Eastern States.

We should certainly advise the Ceylon Tea Fund Committee to offer a handsome bonus to the first man who could prove to them that he had opened a store or agency for the sale of Ceylon teas in the rising town of Denver, the capital of the splendid state of Colorado. There the people are free from many of the prejudices of their neighbours in the Far East—they are a new people. Leadville, a town near Denver, of 14,000 people when we were there in 1884, had all sprung up within 10 years—and many of the people are emigrants from the old country who would gladly drink good tea if they could get it. In that region, we believe, lies by far the best chance for Mr. McCombie Murray. Let him start out West, or send a trustworthy representative, and the day that he can announce the establishment of a Store for the sale of pure Ceylon teas in Denver (and if possible, in Chicago), nothing will be wanting on our part at least, to urge that he should be liberally supported by the Ceylon Tea Planters from their Fund, in his then most deserving pioneering enterprise.

CEYLON TEA AT THE MELBOURNE EXHIBITION.

Planters' Association of Ceylon,
Kandy, 15th Dec. 1888.

The Editor, *Ceylon Observer*.

Sir,—I beg to enclose extract from the *Argus* Supplement, as it gives some interesting information regarding the “Ceylon Tea Room” at the Melbourne Centennial Exhibition.—Yours faithfully,
A. PHILIP, Secretary

EXTRACTS FROM THE “ARGUS” SUPPLEMENT.
Melbourne Centennial Exhibition 1888.
MINOR COURTS.

TEA.—“As the largest consumers of tea in the world, Australians may well take an interest in the tea exhibits on view in that part of the building which is occupied by the Minor Courts. The annual consumption of tea in Australia, according to the latest figures, is 788 lb. per head as compared. 502 lb. in

Great Britain, 0.61 lb. in Russia, and 0.03 lb. in coffee drinking France. Of this the largest amount is at present imported from China, whose teas still hold the foremost position in the commercial world. Of late years however, Indian teas, and still more recently, those of Ceylon, have been attracting a great deal of attention at home, and bid fair at the present rate of increase seriously to threaten the monopoly hitherto enjoyed by China and Japan. The fact, however, seems to be that neither tea is likely altogether to drive out the other, and that there is room for both kinds in a world which can appreciate the good qualities of each. Indian tea having more strength and character than most of the China teas, is found extremely useful in blending with the lighter sorts of the latter. For Ceylon tea it is claimed that, while possessing the strength of the Indian herb, it has a delicate aroma of its own, which is quite peculiar to it, and which must make it a more and more popular beverage as it becomes more and more widely known. From this healthy competition among the various tea producing countries the public have naturally derived considerable benefit. Instead of having to pay, as in the 16th Century, 10 guineas a pound for tea, or 30s, as was the case at home not very many years ago, tea can now be procured for 3s, and of a quality better, probably, on an average than that for which the higher price was paid. Moreover, the successful cultivation of tea in India and Ceylon has provided opportunities for the profitable investment of immense amounts of British capital, and for the remunerative employment of large numbers of British subjects in those parts of the world.”

CEYLON.—“Twenty years ago the island of Ceylon was known as one of the three chief coffee-producing countries in the world, exporting the berry to the value of five millions sterling annually. About the year 1868, however, leaf-blight attacked the coffee plants, and in a very short time nearly ruined the industry as well as many of those who were engaged in carrying it on. At the present time the value of coffee exported annually from Ceylon is reduced to £800,000. Cinchona, cardamoms, cocoa, and other products were tried with varying success, until about eight years ago the planters in despair turned their attention to tea. The industry is still of such recent date that only a portion of the cultivated area is as yet in full bearing. The area at present under cultivation for tea is estimated at about 200,000 acres, the great bulk of which has only been planted during the last few years. Notwithstanding this, the amount annually exported has increased from 114,845 lb. in 1880 to 20,755,779 lb. in 1888, and the estimate from October 1st of the present year to September 30th, 1889, is 32,000,000 lb. Between the year 1884 and 1885, and again between 1886 and 1887 the export very nearly doubled itself. In spite of the increase in production, the average price during these years showed an advance, and Ceylon teas still obtain almost top prices in the market. This is due to the fact that they possess a variety which is seldom found in teas grown elsewhere, and combine the richness and strength of the Indian herb with the delicacy and flavour of the Chinese variety. The diversities of flavour are very great, teas grown at high elevations being noted more for delicacy, and those in lower-lying districts for strength. The climate of the island, with its abundant rainfall alternating with bright sunshine, is particularly suited to the growth of the tea plant, which flourishes where coffee has failed to yield. Labour in abundance is supplied by the Tamil population from the neighbouring coast of India, and is obtained at a cost of about sixpence per head per day. The roads in Ceylon are about the best in the world, and a railway through the centre of the island helps to provide cheap and easy transport to the coast, whence the produce can be conveyed by sea to every part of the world.

EXHIBITS.—“In a prettily arranged but made of bamboo, hung round with photographs of various Cingalese scenes, the Ceylon Planters' Association make a good display of the exhibits. Foremost amongst these, of course, are the teas, of which a great many samples

are shown—some of them (in cases) being fancy teas, and others (contained in bottles) teas known to commerce. Round the stand in the centre are ranged a number of little tables and chairs at which the representative of the Company entertains free of charge all who may wish to try a cup of genuine Ceylon tea. The privilege is, as may be imagined, largely made use of, and every afternoon numbers of visitors are to be seen enjoying the refreshments provided for them. The tea is neatly and daintily served, and there must be few persons who do not pronounce it to be excellent. By those who use Ceylon tea one thing must be borne in mind. Though lighter in colour it is a good deal stronger than most China teas in common use, and about two-thirds of the amount required of the latter will be found sufficient to use in the case of the former. Some samples of coffee are also to be noticed, among which the beans of the Liberian giant, a shrub 6 feet high growing wild in Liberia, are shown in the parchment. Cocoa, coconut oil, cinchona bark, cinnamon, and kapok, a sort of natural silk down, are exhibited. Among the contents of the stand attention may also be directed to a new liqueur called a *Crème de cocoa*, delicately flavoured with cocoa, and forming a most delicious drink.

"Close to this stand may be seen a fine specimen of Cingalese workmanship, exhibited by Mr. Arthur Sinclair, which consists of a massive table of ebony, inlaid with different woods of Ceylon, from the calamandar down to the common jak. The design of the table is cleverly executed, and, it is believed, took many years to complete."

SCALY INSECT ON THE COCONUT PALM IN THE WEST INDIES; AND OUR OWN COFFEE AND TEA INDUSTRIES.

Mr. Hart of the Trinidad Botanic Gardens sends us an interesting communication (see page 476) on a subject which he has seen discussed in our *Tropical Agriculturist*. Besides affording useful information respecting a pest affecting coconut palms in the West Indies, Mr. Hart enters on the general laws governing the epidemic appearance of insect and other pests, a subject which is of special interest to Ceylon with its coffee leaf fungus and green bug insect troubles. Why it may be asked in this connection has no pest, at least in an epidemic form (for the coconut palm has its enemies here like every other plant) appeared in this island on a palm which has been so widely cultivated not for 40 or 50, but for 100 to 200 years? It may be that the narrow area occupied round the coast up to 40 years ago or so was insufficient to induce the condition referred to by Mr. Hart; but still more may be made of the absence of continued droughts such as have affected Jamaica (for three years in one case) and yet again may we not refer to the fact that the latest and best authority (De Candolle) concludes that the original home of the coconut palm is not in the far West—not in South America or the contiguous Pacific,—but more probably in our own East Indian Archipelago with very much the same conditions, of climate at least, as Ceylon.—The case was different with our coffee, and the universal planting of this one product over our hillcountry exactly fulfilled the predisposing cause referred to by Mr. Hart. But he and other observers and scientists should help us now to understand why—when coffee has dwindled down to isolated fields in each district, only the very best being preserved and well looked after with careful cultivation—this new and dire pest of a green scale insect cannot be driven away. We can show Mr. Hart some of the finest coffee trees in the world in Udapussellawa, Haputale, the Agras and Bogawantalawa—bushes fresh and vigorous-look-

ing, full of vegetation, stems as stout as a man's thigh, with no appearance of failing in any way, and yet these same bushes cannot shake off this dire scale pest which not only destroys the chance of crop, but must gradually yet surely affect the vitality. Experiments with kerosene oil, soap, lime, &c., have been tried, but so far without such success as would afford encouragement to persevere. And yet if ever we were getting back to the condition most suitable to keep good coffee in isolated fields free of pest, it is now.—How then about tea which is fast taking the position of coffee in "the days of old," by occupying nearly the whole planting country with one product? Well, one bit of consolation offered is that tea, like the coconut palm, is much more at home in Ceylon than ever coffee was, that our climate and soil are much better adapted to a leaf than a fruit crop, that we can fight any fungoid or insect pest on tea (which can be pruned down till not a leaf is left) far better than we ever could on coffee—that in fact a tea garden might be burnt off, so killing all adverse insect or fungoid life, without permanent injury to the tea roots and stems which in a few months would again display a cover of luxuriant green. This is all very good—and yet—and yet—we should like to see, if it were possible, Mr. Hart's idea of varied cultivation on our plantations more widely followed than it is at present in Ceylon.

TEA! TEA! TEA!

(*Sorrowful Facts from a Sorrowful Man.*)

Tea comes tumbling down once more with that annual and proverbial regularity which is positively disgusting.

I wonder that for very shame the brokers can keep up the old threadbare joke of "inferiority," "falling off in quality," &c. (See the old gentleman's last London letter to the local "Times.")

No, it won't do. These "old man yarns"* may gull the Indian planter away in far off Assam, but we here absolutely refuse to swallow this so regularly dished up viand.

Here is a nice little table I have proved by practice:—

Good teas, good market, good prices.

Good teas, bad market, bad prices.

Bad teas, good market, good prices, comparatively!!

Bad teas, bad market, bad prices.

Tea has evidently no evenly fluctuating value, and the price is as unsettled as a breakwater crab (outsider) during a nor'-easter. To revert to our "wretched fall," every year we sink lower and lower. Once we flattered ourselves that 10d was our limit, but alas for vain delusions, we have managed to touch 9½d or 9d; and at the present rate there will be no difficulty this coming season in getting down to those ouriously shaped and oft repeated numerals, which are the principal representatives of this now rapidly vanishing period of time which is determined by the revolutions of the earth in its orbit. (See *Nuttall*, page 749.)

Why do tea-roller men try to rival the veracity of a certain well-known Biblical gentleman and his better half? Has anyone a tea-roller that will work off the prescribed quantity of leaf advertised, but unfortunately not guaranteed by inventors and patentees?

Why does Mr. Davidson continue making Siroccos? By his last pamphlet there are 1,900 now in use. Many of them must have an easy time of it. I have set them all agoing full speed, and have worked them for eight hours a day for nine months, and dried 90 lb. an hour, and have turned out 369,360,000 lb. of dry tea. I feel perfectly exhausted and must conclude.

* "Old man yarns." No disrespect or allusion to the venerable "J. O.," merely an Australian term: something to do with kangaroos. A squatter friend has sent me copious notes with full particulars, which I will forward.—S. M.

"HOW THINGS ARE DONE IN DIKOYA:"

TEA: PROSPECTS OF FLUSHES AND PRICES—HOW TEA IS TREATED BY LONDON BULKERS: A NICE LITTLE GAME.

DIKOYA, 17th December.

This has been on the whole a very favorable season for tea, and estimates are well forward for the time of the year. Not much was expected from coffee, and that little will in many cases not be realized. The weather has lately been rather cold with a hard wind, which will temporarily keep back the flush in tea, but it is too early yet for dry weather to set in, and next shower will doubtless bring it on as lively as ever. Tea prices are disappointing, and much below last season's at the same time of the year, but I don't think anyone can lay this at the door of the tea-makers on this occasion; so far as I can judge the quality is as good as ever it was, except in those estates where they are taking in first tipplings after pruning.

I trust the London branch of the P. A. will not rest until they have settled this matter of "Loss in voyage" and "Allowance to buyer." The former I heard very simply accounted for by one who had been some years in a leading tea-broker's office in the Lane. In describing the bulking process, he said the boxes were opened with a crowbar, the tea chucked out on the floor, the lead often following; the tea was shoved back anyhow, and in repacking the tea might be put back in the lead, or alongside of it. The bulking men having shovelled back the tea in the boxes and tramped it down with their hobnailed boots spread a sheet of brown paper over it and knock on the lid. On my suggesting that it was impossible to put all the tea back in that rough manner if it had been carefully packed at this end, he said that of course it was not all put back, only as much as they conveniently could, and that the rest was "Lost in voyage." He also described with much humour how useful this loss on voyage was to understrappers like himself, as he could always buy some good tea for a small price, resell it to his friends, and thereby make a very desirable addition to his pocket money. I have no doubt there is a good deal in all this that would help to throw light on the subject, if a parcel of tea was carefully followed through the warehouse and the bulking process; and the sooner it is seen to the better, as, if tea is to go on falling in price, we cannot afford these little perquisites, however useful they may be to the young men in the Lane. Those who are acquainted with tea and how susceptible it is to damp when exposed, will have no difficulty in accounting for the bad keeping qualities of tea subjected to treatment of this sort.

THE KEBANI VALLEY TEA ASSOCIATION, LTD.

We call attention to the Report of this Company on page 467, and to the evidence of rapid progress which it affords. This Company has now 500 acres of virgin forest land planted with tea, with a reserve of 200 acres of forest land. Deralasa which is the name of their plantation, has the advantage of being close to the Yattiyantota bazaar and to the river and cart road, so that facilities for cheap supplies and transport are exceptional. If the young tea does as well as the only field in bearing, at the same age, it is quite clear that the Company's property will be a very valuable one, and we are quite sure that no effort has been wanting in the part of Mr. Forter, the Company's Manager in the island, nor of Mr. Williams, Superintendent of Deralasa, to get good work done in planting and all other estate arrangements.

PLANTING IN BRITISH NORTH BORNEO.—The last British Consular report from British North Borneo describes the progress which is being made there in the introduction of new plants. Last year pepper appeared for the first time among the exports, and much is expected in future from it. It is a remunerative crop, and is rapidly extending in the Bundoo district, where there is such a large infusion of Chinese blood that the people may almost be said to belong to that thriving and industrious race. In the neighbourhood of Sandakan Bay a British company is planting Manila hemp and pineapples for the fibre. The same company is also proceeding with the cultivation of Liberian coffee and pepper, and coffee estates are being laid out elsewhere. It is purposed shortly to give attention to india-rubber and rattans. Both of these plants are indigenous, growing wild in the forests, so that there can be no doubt of the suitability of the country for their production, while, owing to their growing under natural forest shade, their cultivation will not be attended with the expenses incident to the opening and maintenance of ordinary estates. During 1887 applications for 278,335 acres of land were received by the Commissioner of Lands, 218,000 by Dutch and about 60,000 acres by English planters or companies.—London Times.

DIGESTIVE TEA has been a feature among exhibits at recent home Exhibitions, and there seems to be a large sale to judge, by rival preparations. The best known perhaps is that of the Universal Digestive Tea Company Limited of Manchester, who publish a long series of medical and other testimonials to the value of their "digestive tea dried and prepared on a new principle by which the tannin is entirely neutralized and the injurious oils to a great extent extracted." Another preparation is referred to in a paragraph in the *Chemist and Druggist* as follows:—

Lodge's "Dietetic" Tea.—This article is brought under the notice of chemists by Messrs. Lodge, of Broad Street, Birmingham, as one which is "free from injurious tea, and most suitable for invalids and persons with weak digestion." This claim obviously makes the tea a good line for chemists. We have tried it, and find it to be a good liquoring tea, of full body and flavour, and rather under the average degree of astringency. It is attractively put up in tins. We have had the opportunity through the kindness of Mr. Wm. Walker of trying the Manchester Company's tea from a packet about which Mr. Walker writes as follows:—

"I have tried the best quality since I came to Ceylon, and found it not at all satisfactory. It seemed to leave a consciousness behind it of having taken something that was not digestive, but the reverse. I had the same experience on the voyage, and therefore gave up using it. This was a disappointment, as I had been using it at home, and had got to like it. What we used at home cost 3s per lb; the packet we tried here cost 3s 4d per lb. The Company's Secretary at home wrote to me that their process was applicable to India and Ceylon teas as well as China, and that in the 3s 4d quality there was a good proportion of India and (or?) Ceylon. I am not disposed to hope for much from this process. I think that the right thing for those who suffer from indigestion after taking tea, is to see that they use a fine quality of Ceylon tea, and use it after it has been only a few minutes infused. It is the bitter long-infused tea that works mischief in the stomach. In this I feel certain that you will agree with me." There can be no question that Mr. Walker is right, that in nine cases out of ten the infusion rather than the tea itself—due regard being had to the smaller quantity of Ceylon or Indian than of China tea required at a time—to blame for the objections raised about tannin and indigestion. But contrary to Mr. Walker's experience, our trial of the "digestive tea" left a favour. In my opinion of a mild, pleasantly flavoured preparation, though the infusion is, by no means equal in its refreshing qualities to that of our average Ceylon teas.

Correspondence.

To the Editor.

THE COCONUT PALM DISEASE IN THE WEST INDIES.

Botanical Department, Trinidad, Oct. 26th, 1888.

DEAR SIR,—I note that in the August number of your valuable monthly you quote, from the Bulletin of the Jamaica Botanical Department, Mr. Fawcett's notes on the coconut disease, but the mention of my name as having reported on the matter in Sept. 1886 is somewhat misleading, as the enclosed copy will show. Mr. Morris and myself issued reports on the matter concurrently and without the knowledge of each other; but, as my report was only published in the official organ (*Government Gazette*), it did not obtain the publicity that his did, and was actually unknown both to himself and Mr. Fawcett until I called their attention to it after the publication of the article which you republish.

Mr. Morris' report is coincidentally confirmed by my own, and the similarity of the conclusions are somewhat remarkable, the only difference of importance (if any) being in the application of a suggested remedy, and the primary cause of the disease.

It is admitted by Mr. Morris, Mr. Fawcett, and myself that the scale insect is the ultimate cause of death, but I do not think they insist so strongly as I do upon the importance of combating the predisposing cause. Personally I place much reliance upon remedying the primary and predisposing cause when endeavouring to counteract the dire effects of the disease, while my respected co-workers appear to lay much stress upon the urgency of removing the insect pest.

This, of course, corresponds to the usual difference of opinion which is well-known to exist with regard to the many diseases to which vegetable and human life are unfortunately subject; on which arises the question, whether it is better to find and remedy the predisposing cause, or to stamp out the ultimate cause of death, leaving the predisposing one rampant for all ill?

That the former is the more successful policy to pursue would appear to be evident, for when this is done the ultimate or secondary cause generally disappears, after having attained a certain mortality, without the use of any hard course of opposition.

In confirmation of this view I am supported by the opinion, observations and experiments of Professor Harrison of Barbados, who has devoted much attention to the subject since the issue of Mr. Morris' notes on the Barbados trees. For on carrying out the treatment suggested in the 16th para of my report he has been entirely successful where it has been deemed a "hopeless task" to grow them while the "disease is present."

Traced to its primary source, it would appear to be fairly apparent that the so-called disease is in the majority of instances caused by a state of semi-starvation, induced either by drought, or by a deficiency of manurial constituents in the soil of the particular district, and that, when these causes do not obtain, it disappears; unless it has become through a continuity of incidents severely epidemic, when the distribution of the insect pest by winds or other causes would, by the immensity of their numbers, cause healthy and well-nourished trees to eventually succumb.

Although healthy growth, favorable seasons, and a sufficiency of food would probably be in the majority of instances coincident where the balance

of nature is not disturbed, there yet remains the fact, that the assemblage of large numbers of one particular species of plants or animals (man included) is conducive to destructive agents in various forms, which would otherwise or under other conditions be perfectly harmless, and that when a destructive organism or one that has become destructive reaches such a practically unlimited field, where the natural balance of nature is unduly destroyed by the hand of man, it will, and does, work its way, in spite of all the skill that practical experience and scientific effort can suggest, as you must know to your cost in Ceylon with regard to coffee leaf disease, which will probably never be eradicated until the predisposing causes (be they what they may) are removed or disappear.

Plant diseases appear to require the same method of treatment as those affecting man. Our physicians of the present day would not rest satisfied with merely eradicating or staying the ravages of any special disease in the single human body. Where is the doctor of modern education who would be satisfied with stating that 'such and such' a disease was the cause of death without trying to fully understand how the disease was caused, its history and progress, and though he might write *Phthisis pulmonalis* would not understand and treat that disease according to the modern knowledge of its predisposing causes, and would he not also know, how almost worse than useless, were anything but palliative measures in the latter stages of that disease?

Are not the sanitary scientists of the present day doing more for mankind than all the old conservative *drug doctors* of former generations, and why? Because they have searched for and found the predisposing cause of many diseases, and have thus been able to draw up accurate methods of treatment which have enabled them to combat them successfully.

In addition to what is given in my report, I would now add that I am much in favour of mixed planting, *i.e.*, that although each crop should for economy's sake be planted together, still that it should be done in smaller areas than is now usual, and that alternate areas of other crops should be the rule so as to disturb Nature's balance as little as possible, especially where the situation is at all unfavourable.

My report was founded upon returns received in answer to a circular issued under the authority of the Jamaica Government to some of the largest cultivators in that island, and it has therefore more authority than if issued as the result of my own individual experience.

J. H. HART, F. L. S.,
Superintendent, Botanical Department,
Trinidad.

(Extract from "Jamaica Gazette.")

No. 210. 28th June 1886.

The Governor directs the publication for general information, of the following copy of a paper prepared by Mr. J. H. Hart, Superintendent of the Government Cinchona Plantation, embodying results of inquiries made on the subject of the disease effecting the coconut palm.

REPORT ON COCONUT DISEASE.

The importance of an inquiry being made into the disease affecting coconut trees in Jamaica having been proved by continued applications to the Botanical Department requesting the suggestion of remedial measures led to the issue of a circular containing questions, which, it was thought, would tend to elucidate some useful information concerning the nature and extent of the "disease," notes were also made on it by D. Morris, Esq., late Director of the Department, during visits to some of the districts, and notes have also been made in districts by myself.

2. In comparing the returns from correspondents, there appears to be a consensus of opinion that "disease" has only shown itself to be prevalent since the beginning of the year 1885; but it is recorded by one gentleman as having existed since 1876.

3. There would appear to be some districts which are somewhat affected by attacks of the beetle mentioned by Mr. Morris in his annual report for 1881 as being prevalent in the Parish of St. Elizabeth, but the general complaint is of trees affected (1) by an insect known as the scaly blight, and (2) by a "disease" which spreading from root upwards completely destroys the tree.

4. The well-known fact, that many trees of the palm tribe do not show the effects of the injury for lengthened periods after it has taken place, and the facts gathered from the replies of the correspondence as to the nature and progress of the "disease," would lead to the conclusion that its origin is owing primarily to the succession of dry seasons experienced during the last few years.

5. Nearly all correspondents agree that the "disease" proceeds from the base of the tree upwards which would tend to show that the injury proceeds from the root. In all indigenous plants the most vigorous part of the tree and that possessing the most vitality is the centre (known in palms as the cabbage) and consequently it would not suffer so soon as the other portions through which the sap cannot pass so freely.

6. Trees which have suffered from drought or injury of any kind are well-known to be more liable to the attacks of insects than those in a healthy state, and consequently the attacks of the scaly blight may be looked upon as the effect and not the cause or the disease.

7. The "scaly blight" is an insect belonging to the order *Coccidae*, many species of which infest plants in all parts of the world. The females are usually shield-like or convex above and concave or flat on their underside, being furnished with minute legs which when the insect is older become part of the body. On the underside of the insect is a sucker which pierces the articulation of plants and extracts their juices. Soon after impregnation the eggs are deposited and the female dies, her body becoming a shield for the protection of the eggs, their power to increase being enormous. While young both sexes are alike, but the male larva produces two winged insects.

8. The determination of the particular insect which infests the trees has not been decided, but it is probably nearly allied, if not identical, with *Aspidiotus nerii* or "oleander scale," also known as the South Sea Rose.

9. Though the attacks of this insect may be looked upon as a secondary matter, still it does without doubt contribute to the death of the trees, and hence it is necessary to take measures for its removal whenever practicable, or it may become so numerous as to attack and by the multitude of its numbers attack and destroy healthy trees.

10. The means used to destroy similar insects on cultivated plants in England though probably not applicable generally to trees of such height as the coconut may, it made known to planters, lead to the adoption of some plan by which the numbers of this insect may be successfully diminished. One method is to apply a mixture which will effectually seal up the insect for a sufficient length of time to kill them. Others are the use of an emulsion of kerosene oil or the application of spirits of turpentine (but it is probable that the use of the latter would be precluded here on the score of expense); another is to brush them off the surface with a hard brush, seal wounds freely afterwards with strong soap suds; while, yet another is to cut up bar soap into pieces and affix it to different parts of the tree, so that it would be distributed through the medium of the rain. The mixture spoken of may be made as follows—Stiff clay 6 parts, flower of sulphur 1 part; soft soap 1 part; soot or ashes 1 part; quacklime 1 part. Mix with water and then add 1 part in 100 of kerosene oil, and apply to every portion of the surface with a brush in the same manner as paint.

11. To young trees probably, some modification of these remedies may be applicable, but in case of old trees where this pest has made great headway, it is doubtful if they can be successfully employed, and the only course would appear to be to fell and burn the tree at once, especially as it appears that no instance of recovery after being once severely affected has yet been observed.

12. It would be also advisable to cut away as much as possible of the infected portions of young trees and burn them before the application of any remedy, it is however to be mentioned that this precautionary measure has already been adopted by many correspondents.

13. Among the specimens examined were some showing channels made by a small boring coleopterous insect about $\frac{1}{2}$ of an inch in length of which I found several perfect specimens and numerous larvæ, but as it belongs to a class which is generally found among dead or decayed wood it would not appear to be the cause of any serious injury, but had doubtless merely found a congenial home in the dying leaf, stalks and wood of the coconut tree. Many of the specimens that were received were also made into sections and microscopically examined under a high power to see if any fungoid growth had contributed to the death of the tree. Only those fungi were present which we would naturally expect to find on any decaying vegetable tissue and more of them were found traversing the intercellular spaces. From one correspondent a portion of the "cabbage" sent as a specimen was also covered by numerous acaridæ or mites and the larva of a dipterous insect was found in the softest part: these also would naturally be found on any decaying vegetable matter, but they are mentioned here to show that due consideration has been given to every particular as given by correspondents.

14. The attacks of the larger beetle which infests the district of St. Elizabeth's might probably be held in check by destroying them in their channels by the application of bi-sulphide of carbon and then plugging the entrance and by systematically destroying the insects by hand picking wherever seen. One of the larger beetles attacks the plant in its youngest stage, first entering the ground and then piercing the heart; these should be carefully searched for and may often be destroyed by forcing into the orifice by which they enter a piece of stiff iron wire.

15. In view of the foregoing the tendency of the enquiry is to show as before stated that the "disease" is plainly referable to the past dry seasons, and that no great alarm need be occasioned by its occurrence, and that it is probable that with the return of normal seasons it will entirely disappear.

16. I would recommend, however, on a recurrence of drought that the ground around the trees should be well dug for some 3 or 4 yards in diameter and then be covered with a good mulching of stable manure or vegetable refuse about a foot in thickness to conserve and retain as much moisture in the soil as possible during dry periods, and at the same time to afford nutriment to the tree. An application of salt or brine to the roots of trees which are not exposed to saline influences would probably be very beneficial.

(Signed) J. H. HART,
Govt. Cinnamon Plantations, Jamaica.

HOW TO PUSH CEYLON TEA IN AMERICA, ENGLAND, &c.

London, E. C., 16th Nov. 1888.

DEAR SIR,—I enclose a letter which Mr. Murray has asked me to read and forward with remarks. There is much in it with which I agree. If the Tea Fund — its way to give Mr. Murray 6,000 lb. with no restriction as to gratuitous distribution, but conditional upon his purchasing 12,000 lb. for the American market, and thus obtaining 18,000 lb. 33 per cent below market rates, I believe it would be a good thing both for the grower and Mr. Murray; and if the Tea Fund should see its way to help Mr. Murray in the way of advertising, I think it would be a step in the right direction, because in this

direction he is specially handicapped. All dealers in Ceylon tea in the United Kingdom receive a great deal of gratuitous advertisement from the many interested in Ceylon scattered over the Kingdom, but across the Atlantic where advertising is far more necessary this gratuitous assistance is not forthcoming. But while I should be very glad to see Mr. Murray helped, and knowing something of the struggle he is having, I think he is deserving of all help.—I object most strongly to anyone imagining they have a claim upon the Planters' Association of Ceylon for their championship of Ceylon tea, more especially when that championship is self-constituted. I remember pointing this out at a meeting in Kandy, and now that I have seen something more of business, I hold the view more strongly. The Planters' Association should have nothing to do with trade, and the moment it takes any special tradesman under its protection, it places itself in a very invidious position: the clamorous receive help which the more modest but perhaps more deserving do not apply for, and instead of keeping the retailer and producer in harmony, a section of the trade is at once irritated.

I can imagine no case more deserving of, and more directly appealing for aid to the Tea Fund than that of Mr. Horsfall of Bournemouth, who, after having overcome the difficulties inseparable from the establishment of a new business, suffered serious loss, direct and indirect, from his premises being burnt down; but so far as I know he has borne his loss uncomplainingly while others who have ventured on their own account to introduce Ceylon tea into foreign countries and who may have lost in so doing, clamor for assistance. I, like many others connected with Ceylon, am constantly trying new markets for tea, but I do so as a tea dealer and not as a member of the P. A., with the full responsibility and with the full intention of pocketing all profits if any, derived from my ventures. I value the P. A. of Ceylon far too highly to desire to see its field of usefulness impaired, or its name in any way degraded, and I could not but regret lately to see a firm advertizing as a special inducement why people should try Ceylon tea from it, "That its partners were members of the Planters' Association of Ceylon." Of course if buyers knew what this meant they would not attach much value to it, and they would just as soon think of buying their butter from a man because he happened to be a member of an Agricultural Society; but the buyer, as a rule, does not know what the P. A. of Ceylon is, and such an advertisement either means nothing, or conveys the false impression that the P. A. of Ceylon is a tea-trading body; and woe betide the tea planter of Ceylon if that idea once became prevalent. I believe Mr. Murray to be on the right path in not trying to force pure Ceylon tea down American throats. In America as in Europe if prices are to be maintained, the great bulk of Ceylon tea must be used for blending.—Faithfully yours,
J. L. SHAND.

Philadelphia, 25th Oct. 1888.

Dear Sir,—In view of possible business relations being formed between myself and other parties resident in or connected with Ceylon, I would like to express my candid opinions on certain subjects, at the risk of being considered heterodox. If such is the verdict, I must be content to plead guilty, for my convictions are at least honest, being the result of every day experience, and a pretty intimate acquaintance with the tastes and habits of American tea-drinkers.

"Ceylon tea is not appreciated over here" is an oft-repeated assertion, and sounds like "a chesnut," as the Americans term it; but, as you are not armed with "chesnut" bells in Ceylon, I am courageous enough to

repeat myself until you cable me that your columns are forever closed against me. No one is so tired of hearing this not very encouraging piece of information repeated as I am, and I only stand it because I know it is but too true.

Will Ceylon tea ever be appreciated in America?—In the opinion of Americans who ought to know, it will, in time, be appreciated by a minority of American people, but never by the majority. In other words, it will never be the popular tea of America. To this reservation might be added—unless Ceylon and India can successfully compete with the Foochow or Formosa Oolong by producing a tea of similar character.

Is the demand for such a tea as Ceylon now produces sufficient to support or warrant the establishment of a business in that tea to the exclusion of others?—No! emphatically no! The ready demand is nominal if indeed existent at all. Any demand for the tea has to be made by constant advertizing, involving great outlay and indefatigable energy on the part of the pioneers who undertake to introduce it. What is true of an agent undertaking to introduce it in a small way, is applicable to a Company of large capital on the greater undertaking. Money spent in judicious advertizing, with plenty of push and energy, will create demand, but not in proportion to the expenditure. The question then arises

Who ought to bear "the initial loss inseparable to making markets"?—Why—surely those whom the making of the markets benefits. The pioneer who does the practical work is certainly more or less benefited when the market is made, if he is fortunate enough to pull through, but if unassisted the chances are that the making of the market proves his ruin and the fortune of those who follow.

Who benefit by the making of the market?—Perhaps the easier way to put this question would be to put it in the negative form, and ask "Who does not benefit by the making of the market?" The whole country is undoubtedly benefited, and the Government must be looked to as headquarters. The planters are perhaps the most directly interested parties, and they have responded liberally to the suggestions of their leaders.

The next point I would touch upon is *how best to aid pioneers in their work*. No private party can be expected to face certain loss and possible ruin, to serve the interests of a whole community. The same applies to a company formed to carry out a commercial enterprise. If they do so, they have a right to ask the support of those who ultimately benefit by their work.

Mr. Shand has suggested one means by which a pioneer can be effectually assisted. If on purchasing 2000 lb. of tea he received 3,000 lb. he could afford to put the tea into successful competition with all other teas and at the same time make a large profit. Had I been able to secure tea on these terms last week, I could have placed 12 chests of tea in very good hands. As it was, an Assam took its place at a few cents cheaper than I could afford to tell. I had a talk with Mr. Finley Acker three days ago, and he seems to think he could double his exertions if I could let him have the tea at about London market rates, which I could do if I could secure the tea on such terms as Mr. Shand suggests.

Another means of assistance occurred to me as reasonable and fair. What are the expenses which the pioneer feels the most? Not the rent or fixtures necessary to the adornment of his place of business. These are common to all manner of business. It is the necessary advertising of a new article. It is not the excellence of the article itself that makes the market so much as the *advertising* of the article. The consumption of pure Ceylon tea is dependent on the amount of advertising done for it. Advertise for me and I will guarantee the sales. Now, if the Chamber of Commerce would vote \$1,000 to be handed over to Mr. George W. Childs of the *Public Ledger*, I think I could prevail upon that great philanthropist to give good value for the same in the "personal" column, which 99 out of 100 ladies of Philadelphia read every morning with perhaps more regularity and interest than they read their Bible. If there could be inserted in this column of interest, such an advertisement as "Have you tasted Ceylon tea? it is absolutely

pure, the finest flavored of all tea, and very wholesome and economical. Can be tasted free at any time at our office. J. M. M. & Co." &c. I think it would do more to assist me to dispose of Ceylon tea than anything that could be done for me. It would be making me a present of so many hundreds of customers per annum—a welcome present for me and a direct benefit to the donors.

What would serve me well would serve others in like position. Assist them by advertising Ceylon tea on the general interest principle, and let THEM derive the benefit of the sales.

I have enlarged on this subject, because it means the making of my business if I am assisted in this way. I called on Mr. Childs the other day with the view to finding out what he would allow upon his usual terms for such an advertisement, but found him away from home. I will see him shortly on the subject, and sound him, although I assure you there is no necessity for those who would thus assist me waiting for any further information. An official note addressed to Mr. Childs, asking him to draw upon them for any sum they may grant for this purpose, would be attended to at once and acknowledged by return of mail.

How can unsupported pioneers assist themselves? Personally speaking, I had to assist myself, not only by finding money to keep things going, but by taking a sensible angler's view of my position, and changing my fly, or rather adding a new fly—and I think I may truthfully assert that this step helped me to keep "a stiff upper lip" when my heart was very near failing altogether. There are two ways of winning a battle. It may be won by storm, but it can also be won by stealth. This was the principle with which the second fly was dressed. "What will the *Observer* say to my using this bait?" thought I to myself when I gave Messrs. J. H. Catherwood & Co. an order for a few chests of Formosa Oolong and young Hyson, a venomous looking article forsooth. Well! I had no choice in the matter. If Frenchmen eat frogs and enjoy snails, they have a right to enjoy them, and so have Americans to prefer the tea they have been used to, to Ceylon which they never tasted or heard of before. I saw a goodly number of people every day, who averred that they would like to deal with me, but that, to be honest, they did not fancy Ceylon tea, or their people did not like it. It dawned upon me that, while I accused Americans of prejudice, there might also be a little prejudice in my mind also. I accordingly asked Mr. Reid to furnish me with really good samples of the aforesaid teas, and after a week's tasting, I came to the conclusion that a very palatable blend of Ceylon, China, and Japan tea was not only a possible thing, but a tea that was calculated to suit almost any taste. I no longer winced under the ill-disguised expressions of displeasure or disappointment which I had accustomed myself to expect on a customer first tasting the tea I catalogized so much. If it did not suit, I presented cup No. 2, and if that did not suit, cup No. 3. One of these was sure to please, and they all contained a large percentage of Ceylon tea. These blends proved universally acceptable in the event of the pure Ceylon not being liked, and, in selling the blend tea, I invariably gave, as I now do, a 2 oz. sample of the pure article with a perfect halo of eulogies to enhance its value. I always give pure Ceylon the first chance, but in the event of the person to whom I give it not liking it, I never force a sale, as I have learnt to my cost that it is a mistake to do so. The additional custom thus secured makes the difference between a losing and a self-sustaining business. The only people I never ask to taste pure Ceylon tea are green tea drinkers, as to do so is to encourage wicked thoughts and suppress bad language. I give them one-third Ceylon with the two-thirds of young Hyson, and they submit.

I know that many will think they see in this letter the first tokens of "throwing up the sponge" in the cause of Ceylon tea, but my object in writing is to claim precedence for this system of introducing pure Ceylon tea as the most sensible and practical of all systems, and I think I have tried most and paid well for my experience.

I sat down to this letter about three hours ago with the determination that I would make a clean breast of every heterodox opinion I suspected myself of. I have heeded the lion in his den, which I am glad to say is 13,000 miles away, and can only hope that not only he, but all his readers, will look upon me, not as a backslider, but as one who has been persuaded against his will to follow the course of his convictions, and by presenting a palatable blend of Ceylon with China and Japan teas to the American people, demonstrate to them, not that Ceylon tea is improved by the introduction of these teas, but that these teas to which they have been accustomed, is improved by the introduction of Ceylon tea, which, I endeavour to persuade them, they will eventually come to like and appreciate as a pure wholesome, and economical tea.

I cannot stop without a little reminder that I am in need of assistance. I never occupied the unenviable position of a beggar, but it appears to me that I am doing justice, not only to myself, but to the cause in which I am engaged, when I claim the assistance I really need.

My capital has never been large, having buried the greater part of that commodity in the sloping subsoils of Dolobage, but I have worked with a will, and pushed Ceylon tea for all it is worth. "It now appears I need thy help," and I think I can reckon on the echo "Well, be it so." I have been successful in establishing quite a business, but constant advertising is necessary, absolutely necessary, and that it is that handicaps me. I am not in any way discouraged as to the future of Ceylon tea. What concerns me most at present is my own future, for it is a struggle all the time. The fact that it is nearing the presidential election paralyzes business and makes it all the harder for me, but I keep at it all the same.

I send this letter through Mr. J. L. Shand, to whom I am writing, and he may add a few remarks which will be very acceptable from one of his experience in the pioneering line. I will now close, as I don't wish to occupy an entire daily issue.—I am, yours very truly,
J. McCOMBIE MURRAY.

Philadelphia, October 24th, 1888.

Mr. J. McCombie Murray, Phila. Dear Sir,—We are in receipt of your inquiry as to our opinion of the Ceylon tea prospects in the United States. In reply would say that our opinion, based upon actual experience, is that Ceylon tea can be sold in this country, provided sufficient interest is manifested in educating the public to appreciate it, and provided skill and tact are employed in introducing it. This work costs money to the educators, and you need not be surprised at the apparent indifference of the trade so long as there is no "moneyed" advantage for them to take this trouble. We have spent considerable time and money in pushing and advertising Ceylon tea, and believe that if we could purchase the tea at lower prices, or receive a rebate with the understanding that it is intended for advertising purposes, and to warrant the employment of labour to push it, that we would push it in many sections of the United States. While we cannot say what this would amount to, we are justified in predicting a very large increase on what we have done up to this time. If you could succeed in getting some rebate of this kind for us, it would stimulate us to do all that we possibly could to push its sale.—Yours very truly,
FINLEY ACKER & Co.

A CHANCE OF A PRIZE FOR CEYLON TOBACCO GROWERS.

Colombo, 14th Dec. 1888.

DEAR SIR,—Under the above heading a paragraph appeared in last night's *Observer* stating that the London Chamber of Commerce offers a prize for the best specimen of Colonial grown tobacco weighing not less than 100 lb. For the information of Ceylon tobacco growers, permit me to say that a prize of fifty guineas was offered in March last, and the conditions respecting same

appeared in the "Ceylon Advertiser" for April.* The Colonial tobaccos competing for the prize had to be in a London bonded warehouse by the 1st December, but from inquiries I made before leaving London, I do not think a single Ceylon grower sent home a sample.—Yours faithfully,
W. H. DAVIES.

"POOCHIES" ON TEA.

Park, Lunugala, Dec. 14th.

DEAR SIR,—I send you by today's post in matchbox some specimens of caterpillars which have attacked my tea bushes. They start on a bush and eat every leaf off until they leave it so many bare sticks, and then they go to the next bush. Can you tell me what they are, or suggest any way of exterminating them?—I am, yours faithfully,
B. FFANSHAWE.

[Mr. A. P. Green reports:—"Larva of a small moth, which I am unable to identify at present, the caterpillars having passed into the chrysalis state." As for prevention, we repeat as follows:—Where numerous, and causing much injury to the trees, the caterpillars may be collected by hand and destroyed. For caterpillar attacks on fruit trees in England, Miss Ormerod ('Manual of Injurious Insects and Methods of Prevention') advises good drenches of soft soap and fish-oil, or soft soap and sulphur thrown powerfully at the foliage. Although remedies of the above nature might be found to have an unpleasant effect on the tea leaves, caterpillars are very susceptible to injury from wet and cold in their young state and when changing their skins; and strong syringing with cold water where at hand might be tried with good effect if done in the early morning. Caterpillars being generally night-feeders, soft soap could be used in the evening, to be washed off by a good drenching with pure water the following morning. Except where the boughs touch, the caterpillars can only travel to another tree by crawling up the trunk, and where the attack is severe, the surrounding trees might be protected by placing rings of some deterrent at the lowest part of the trunk, or on the ground round about it. A thick band of hay or straw, soaked in a mixture of tar and oil, that would keep wet and sticky for some time, would effectually prevent the caterpillars crossing it. If the attack is confined to a limited area, surrounding the whole with sand or ashes well sprinkled with paraffin and water would check their further progress. (See Ormerod, 'Injurious Insects,' &c."—Ed.

CEYLON TEA IN ENGLAND.

Wattegama, 17th Dec. 1888.

DEAR SIR,—I wish to call your attention to the harm that is being done to the tea industry by the shipment and sale in London of the lowest qualities

*The London Chamber of Commerce are offering a price of fifty guineas for the best specimen of Colonial grown tobacco. The sample must weigh 400 lb, embrace an average of the growth, and not consist alone of leaf picked from a larger quantity than that which is submitted to the jurors. It is nevertheless desirable that the leaf should be assorted in the usual way, into sizes or colours, separately packed, each sort being left in its natural proportion to the bulk. The Colonial specimens must be in any London bonded warehouse on or before the 1st December next, so that they should be shipped from Colombo not later than the middle of October. We do hope Messrs. Ingleton, Vollar and others will send in samples for competition. If they do not obtain the prize, they will at any rate be advertising Ceylon as a tobacco producing country, and at same time be obtaining some valuable experience as to the exact requirements of the London trade. We need hardly say we shall be glad to take charge of any exhibits, personally look after them, and obtain all the information we can regarding preparation, etc. We have now procured a supply of the conditions and necessary forms to be signed and sent home by intending exhibitors. They can be obtained on application at our Colombo office.

of our leaf. These teas are entirely bought for the packet trade and sold to the public as pure Ceylon teas. Now that we have a certain amount of protection, I trust, under the Merchandise Marks Act, it is simply suicidal to continue shipping rubbishy teas. The price of the lowest qualities is at present remarkably high compared with the better qualities. This is entirely due to the competition of the packet trade. I saw and tested many samples in England of stuff that could only by courtesy be called tea, all of which Messrs. Gow, Wilson & Stanton assured me went into packets. The harm done by this to the good name of Ceylon is very great, and although I'm aware of the probable impossibility of stopping the shipment of such teas, I think you should direct the public attention to the matter.—Yours faithfully,

BERNARD NELSON.

AN OIL TREE IN DRY REGIONS.—Mr. Joseph Thomson in his paper before the Royal Geographical Society, Nov. 26th on "A Journey to the Atlas Mountains" made the following reference to a tree like our own palmyra that is independent of irrigation:—With their arrival at Tensift commenced the area of Argan forest, that peculiar and useful oil tree which found sustenance where the more water-loving olive could not live.

VANILLA GROWERS' TROUBLES.—A correspondence is now proceeding in the Mauritian journals on the serious depredations to which the vanilla plantations on the island are exposed. The fruit-bearing plants, when the pods begin to ripen, are torn off in hundreds by midnight marauders, who recommence their robberies every season, and pursue them apparently unchecked. The theft have increased to such an extent this year that the planters protest that they will have to give up the growing of vanilla and turn their attention to crops less liable to theft unless stringent measures are taken to stop the nuisance; for not only do they lose a proportion of their crop so large as to nearly equal their margin of profit, but the thieves, who have to cure the stolen fruit hurriedly and secretly, are spoiling the reputation of the Mauritian vanilla by throwing quantities of ill-cured and imperfectly ripened beans upon the markets. The planters suggest that the Government should prohibit the transport of vanilla beans by night or without a pass, and they say that in the neighbouring island of Bourbon, where a similar measure was adopted, the thefts have almost entirely ceased.—*Chemist and Druggist*

COTTON MILLS IN BOMBAY.—We attract attention to the readable and apparently exhaustive review of the Cotton Mill industry in Bombay afforded on page 467 from a correspondent of the *Bombay Gazette* who is evidently well up in his subject. He gives elaborate tables of the results of the working of the mills under English, Parsee and Hindu management, all of which we reproduce in full. We need only here repeat a sentence from his summing-up, to the effect that on a total outlay of capital of R31,500,000 the cotton industry in Bombay has made a gross return of R5,800,000 or over 18 per cent, and the writer well contrasts this with Scottish investments to the extent of 12 millions sterling in America and the European Continent which had not, when reported three years ago, yielded a cent of profit for many years! How is it that such capitalists do not come forward to supply the capital of the first Cotton Mill in Ceylon (raised mainly through local agency), or of the several Tea Companies which might so advantageously be formed by putting together from six to a dozen of existing tea plantations, here and there, all over our planting country? Let those interested send today's and yesterday's copy of the *Observer* home to both Scottish and English capitalists!

THE HARITAKI NUT.

To the Editor "Indian Agriculturist."

Sir,—I remember to have seen some time ago a paragraph in the *Statesman* relating to the discovery of a certain herb which, when chewed, destroys the taste of every other thing put into the mouth. The discoverer was congratulated upon having conferred a boon upon men. But this is no new discovery. We have a certain nut called *haritaki* (myrobalan), pieces of which when chewed render everything tasteless. I have myself tasted it and have found that even quinine appears tasteless after it. It grows in the Southall Pergunnahs in a wild state and is sold in the bazaar when dried. Our widow ladies are in the habit of chewing it after their meals. It is slightly bitter in taste. I think it may well be used as a destroyer of the tastes of bitter medicines. First chew a bit of *haritaki* and then take the medicine. You will not know what you are swallowing. I daresay some medical experts will come forward to test it, and to give their opinion as to the harmlessness of our using it. I beg to enclose herein some bits of *haritaki* for your inspection.

Yor.
[Seeing that the myrobalan is used as a tanning material, we should think any large use of it as a masticatory would be extremely hazardous.—Ed.]

TEA AND TOBACCO IN JAPAN.

BRITISH CONSULAR TRADE REPORT FOR NAGASAKI FOR 1887.

Owing to the primitive and careless methods of cultivation and preparation in the surrounding districts, tea has virtually ceased to be an article of export, except to the North of China, which takes large quantities of very inferior kinds, ranging between 4 dol. and 5 dol. per picul.

There were but small purchases at the opening of the year, and, though prices declined, the rise in sterling exchange prevented any advantage being taken of this fall, which was about 2 dol. in medium to fine, and 1 dol. 50 c. for better kinds. In May the new season teas made their first appearance and seemed satisfactory, being apparently up to standard. The unsatisfactory nature of advices by mail, however, stopped business, exporters being unwilling to operate except at a reduction of 2 dol., bringing prices in July down to 7 dol. to 9 dol. for medium to fine, and 10 dol. to 13 dol. for fine to finest. Business continued dull till October, when concessions on the part of Japanese merchants induced buyers to operate to some extent, though the market remained flat, notwithstanding prices had, if anything, lowered. Stocks at the end of the year consisted of—fine, 600; medium, 2,000; and round leaf, 850 bales.

The out-turn of tobacco proved even worse than was expected, and business was therefore specially dull at the commencement of the year; notwithstanding inferior quality, some 3,380 bales were held in February for 6 dol. per picul. Later on concessions led to business, and in April there were only 2,600 bales in stock, of so very poor and inferior a description as to render it impossible to find buyers.

This state of things continued throughout the year, the new crop being unusually small and bare. Stocks on hand in December were 2,485 bales, with merely nominal quotations and no inquiry.—*Japan Weekly Mail*.

LADY AGRICULTURAL PROFESSORS.

Our Paris correspondent writes:—"Russia has more lady doctors than any other nation; and soon she will have more lady professors of agriculture, and more lady directors of model farms. In the north of Russia, model dairies and breeding farms are very numerous, and are superintended by women and worked by their own resources. They send young ladies to Germany, France, Holland, Denmark and Belgium to study special features in farming. Madame Grunow has converted her estate at Sussulitz into a practical school for teaching peasant girls kitchen gardening, the rearing of bees, how to keep poultry, the care of stock, the management of a dairy, cooking and household management. Each pupil must be

fifteen years of age, and fully understand what she has come to learn. Eight months is the period of residence, and the school aims not exactly to train the girls, but to fill their heads with practical notions, and to develop self-reliance and the thinking faculties. The teaching system is original; there are no classes, no lectures, no professors. At five in the evening the girls sit around the directress, and she asks each pupil to relate what work she was engaged in during the day, what she found to be difficult, and what she did not comprehend. Explanations are lucidly given and questionings encourage with references to standard works bearing on the subject in hand. The girls are thus encouraged to love knowledge in seeking it themselves. This is the ancient Greek system, the peripatetic, only mistress and pupils sit instead of walking about. Then the pupils examine one another, the directress 'cutting in' as required. Women who are pining to have work, and are embarrassed how to employ their surplus wealth, have here a wide field and a noble cause."—*Madras Mail*.

FORESTS OF URUGUAY.

Among the best wooded provinces of Uruguay are Cerro, Largo, Paysandu, Salto, Soriano, Maldonado, and Minas, and the trees of native growth are generally those of a temperate climate. The United States Chargé d'Affaires at Montevideo says that every description of poplars, willows, and alders flourish. Among other trees are the *algarobo*, from the pods of which the natives distil an inferior kind of beer called *chica*. The tree is much prized for timber, and it is stated that cattle thrive upon its buds and foliage. The *unuday* is a lofty tree which is said to resist decay in a most remarkable manner, and Mr. Bacon states that he has seen logs of this tree, said to be over two hundred years old, which evinced no signs of rot. It furnishes immense logs, often sixty feet in length and thirty inches wide. The timbo or canoe tree is valuable for making rough canoes, as the trunk which is very large and generally hollow, is scooped out, and the rude and frail bark is ready for the fisherman. The *yata* is a tree of exceedingly slow growth, taking over 100 years to mature its fruit, which, like that of the carob tree, is excellent for cattle. The *carrouday* (a large fan palm) is of great use to the poorer native classes, as it makes an excellent roof for their huts, and is easily placed and replaced. The mimosa and cedar grow in great numbers, and this wood is capable of great polish. Among other trees may be enumerated the *lapacho*; the *nanduy*; the *ombu*, resembling a fig tree, but much larger, prized for its shade; the *telano*; the *chanar*, a thorny mimosa, and many others. The absence of the oak, the pine, and the fir is noticeable, and it is stated that many efforts have been made to grow them, but without success. Of the foreign or imported trees, the eucalyptus from Australia is the most flourishing. There are hundreds of groves of this most flourishing tree in the environs of Montevideo. It is said to be a preventative against malaria, and although extensively grown, there appears to be one objection to it, namely, that it impoverishes the soil around it for many yards, so that no other tree or shrub can flourish in its neighbourhood; and its roots penetrate to such a depth, and entwine every object within their reach to such an extent as to uproot pavements and tombstones, although considerably removed from the trunk of the tree itself.—*Journal of the Society of Arts*.

DRAINAGE—HOW IT AFFECTS VEGETATION.

The Queensland *Planter and Farmer* says:— If a sample of common soil is examined with a magnifying glass, it is found to be composed of numerous fragments of mineral of various kinds, humus, muck, and often of undecomposed vegetable or animal matter. These fragments are very irregular in form and size, and are in contact only at their more prominent corners. They might be compared

to a mass of coal of various sizes mixed together, the difference being that the fragments of coal are all of one substance, whereas the soil is composed of various substances. Now we know that if we pour water over a basket of coals, a thin layer of water adheres to each fragment, and the rest passes off through the meshes of the basket. Just so, when a soil is wet by the rain, each tiny fragment is surrounded by a thin film of water, and the rest, if the soil is in a normal condition, filters through and flows away. As the fragments of the soil are very much smaller than those of the coal, while the film of water that adheres to the particles is perhaps just as thick, it follows that the amount of water retained by a given bulk of soil is vastly greater than by an equal bulk of coal.

Suppose we put the coal in a light pail instead of a basket, and then pour on water. Of course the water fills the interstices between the fragments and the air is all driven out, except a few bubbles that become entangled. This is precisely what happens when heavy rains falls upon a soil that has an impervious clay subsoil. The spaces between the particles become almost filled with water, and the air, with the oxygen it contains, is mostly driven out.

Botanists tell us that the root-hairs, that supply the roots with water and its nourishing substances in solution, cannot live without oxygen. If the oxygen is shut away from roots, therefore, the roots will die. In dying they not only injure the plant to which they belong, but the matter of which they are formed soon undergoes decomposition, and generates gases which are injurious to other healthy root-hairs in the neighborhood.

It is to be sure, the rain water, as it falls upon the soil, is charged with oxygen, but in passing downward a part of this is filtered out; another part unites with organic matter in the soil, so that after the water remains for a time it becomes deficient in the life-giving oxygen. Hence it is that when a soil is filled with water the roots of land plants cannot live in a healthy condition.

When, however, we provide an outlet for the surplus water, it slowly flows away, and in doing so the air forces itself in from the top of the soil, and the roots are abundantly supplied with oxygen. From time to time rains come, and temporarily filling the cavities of the soil, drive out the air within them that has given up a part of its oxygen. As this passes off through the drainage fresh air enters again, and thus the roots are kept supplied with oxygen.—Ex.—*Southern Planter*.

PLANTING IN TONG-KING.

The *Revue Française* contains an elaborate article^e by a French colonist, writing under an Annamite *nom de plume*, on the agricultural colonisation of Tong-King, in which a glowing account is given of the possibilities of a settlement of European agriculturists in that country. After describing the climate throughout the year in some detail, in rather favourable terms, the writer states that the views prevailing in France as to its dreadful nature are due wholly to losses of the expeditionary corps from the climate; but this is not a fair criterion, because the difficulties and dangers of these expeditions from the long marches of the troops through unhealthy regions, with unsuitable food, no proper camps, and the excessive heat would cause a high mortality in any case. With ordinary care and periodical changes life in Tong-King, he avers, is as healthy as anywhere else in the tropics, and therefore the climate cannot be regarded as hostile to the suggested enterprise. Next, Tong-King offers the two main elements of fertility, the sun and water; the means of communication, which are all by water, are cheaper than in almost any other country in the globe, labour is on the spot, and to be got at a cheap rate, and the crops that may be cultivated are numerous and varied. But the great danger to be avoided is in specialising, that is, in cultivating one thing and

one only. This baneful practice prevails amongst European planters all over the East; one man will grow tea only, another coffee only, a third pepper, tobacco, cocoa, or what not; and when anything occurs to injure his crop or reduce the price, he has nothing to fall back upon.

Specialising is sometimes necessary; as when the sugar-cane planter is far away from markets he must have the machinery at hand for the rapid treatment of the cane, and must give himself up to this altogether. Tong-King further has the enormous advantage of abundant and cheap labour; immigration is not necessary, and thus one source of heavy expense to the planter is saved. The delta region is not suitable for European planters, on account of its flat and unhealthy character, but the rest of Tong-King is composed of hill and valley, where Europeans can carry on their work all the year round. The writer proposes that France should come to an arrangement with the King of Annam, who is lord of the soil in Tong-King, to take over his rights in regard to the land, and then that it should be sold by public auction. He even sketches out a plan or draft of a law regulating these sales, protecting the rights of all concerned. He is obviously fully possessed with the idea that Tong-King as a planting country can not only vie with Java, Sumatra, the Malay Peninsula and Ceylon, but can beat them all in point of prosperity, inasmuch as it enjoys advantages which they do not possess in abundant labour on the spot, and in a system of the cheapest possible transport by rivers and canals, which would convey their produce rapidly to the ports on the coast, where it could be shipped to Hong Kong and European markets.—*London and China Express*.

MINOR AGRICULTURAL INDUSTRIES.

Under this heading a correspondent to the *Demerara Argosy* writes as follows with reference to the cultivation of Cocoa, Indiarubber, &c. As his remarks are likely to be of great interest to our banana cultivators we give them at considerable length in the belief that if the policy indicated below was pursued by the planters generally in this Colony, a permanent source of income would obtain. We are thoroughly convinced that the future prosperity of tropical countries lies in the carrying out of the undermentioned scheme of cultivation, a cultivation which should go hand in hand with opening up of all the modern means of internal and external communication:

Were there, however, a large permanent demand for export, of either bananas, plantains, ground provisions, or the products of any other annual plants, the cost of establishing cocoa, or any of the several permanent economic plants, would be greatly reduced: as, for the first few years these crops would more than pay working expenses; the cocoa, &c. in the meanwhile becoming established on the land. A resident cultivator, having less means, might be content with establishing a small area at first, waiting till the returns from the produce enabled him to extend it. Thus an industrial man, however poor in starting, might, as the majority of settlers do in temperate colonial countries, work his way upward in life to eventually a considerable possession. But to men of little or no capital, situated like the majority of agricultural colonists who begin life in temperate lands, a fruit or other trade, yielding returns at short intervals, and so enabling them to live and pay their way, would be indispensable to their success as cocoa cultivators.

Now the cultivation of cocoa, coffee, kolanuts, coconuts, the various spices, possibly fibres, the numerous small tropical products, and various well-known tropical fruits, to which might be added the breeding and rearing of stock of all kinds, presents just the opening required by such men.

Now let me say a word as to the kind of men who should become settlers on our rivers,—the men who would carry with them in this new industry

and enterprise the probability of success. There is a class of men in this colony, almost exclusively of British birth, possessing the necessary training and experience for the successful and economical management of agricultural property, to whom these smaller industries offer a specially useful and successful career. I refer to overseers of sugar estates.

But I do not confine recommendations of riverside agriculture to overseers or managers of sugar estates alone, I simply mention these as a class of men specially fitted by training and experience to undertake it, and who require some such opening in life to make up for the lack of opportunity in the sugar business; any man of energy with aptitude for the calling, prepared to meet alike the difficulties and advantages or pleasures of pioneer life, would no doubt succeed.

Besides the culture of the several subjects mentioned, I may describe how the value of riverside property might, by men of foresight, possessing the spire of patience, be in the future greatly enhanced. Many of the native products of the colony such as tonka beans, souari nuts, brazil nuts, crab nuts, indiarubber, guttapercha, balsams, some of the rarer and more valuable woods, barks, medicinal substances, poisons, &c. For all of which there is a large permanent demand but a very inadequate supply from the natural sources from which they are drawn, would be of value could they be procured or produced cheaply; but they are so scattered through the depths of the forest, and widely dispersed in the colony, that to procure them in any quantity a very large expenditure is necessary. Here, on the very outskirts of cultivation, all these things might be gradually established in quantities that in the course of a generation, or a lifetime, would be of appreciable importance in the income and value of an estate. The new trees could be gradually substituted for the forest found on the ground by planting the seeds beneath it, or by setting the plants, which could be raised systematically for the purpose,—the original trees being taken down gradually as the new ones required the room. Long before an average life had run out, the majority of the trees would be in the full vigour of youthful adolescence, with a long and vigorous existence before them. This is no utopian dream, but a possibility within the realisation of any young man with the necessary means and spirit of self-control, perseverance and industry.—*Guatemala Star*.

CONCERNING QUININE.

As our market reports of late have shown, there are indications of a reaction in quinine. The improvement, as usual, began in London, and was communicated to this market which, however, has so far failed to respond fully, some subtle influences apparently being at work here to prevent any appreciable advance in prices. That the conditions are favorable to higher prices is generally conceded. The consuming demand for quinine has been unprecedented since the advent of warm weather increasing in volume as the summer advanced, and up to the present time there has been no abatement in the demand, while there is a good prospect that it will continue as large, if it does not become heavier, until late in the fall. This is but one element tending to improve the position of the alkaloid, other and perhaps more cogent reasons existing to encourage the advance. Prices, it is now contended, have been too low in comparison with the price of bark to be profitable to the manufacturers, yet the latter are responsible for the low rates that have prevailed since the beginning of the year. This condition of depression was artificially produced by the policy pursued by the manufacturers in keeping prices down, until they had secured adequate supplies of bark at low figures, or as some believe for the purpose of curtailing competition by freezing out competitors. If either or both of these were the actuating influences in the recent depression, they appear to have failed of their object. Some of the foreign manufacturers have permanently expanded, and as far as increasing the price of bark, the manufacturers' tactics have been of no avail.

The position of bark is a particularly strong one, which was indicated to an extent by the recent auctions in London and Amsterdam, and will be, probably, more decisively demonstrated at the approaching sales. At any rate these late sales tend to show that there is a bottom to the bark market beyond which it is idle to expect prices to go. It is unnecessary to review the causes which have operated to produce the present conditions controlling the market for Ceylon barks. Suffice it, that, so far as the statistics have been made up, there is a shortage in the shipments from Ceylon, amounting to three million pounds less than the quantity shipped during the corresponding period last season. Meanwhile the shipments of Java bark have increased one million pounds over last year. The Java being richer in quinine than the bark now coming forward from Ceylon, the increase in the shipments of the former should more than make up for a corresponding decrease in the Ceylon shipments, and this would be so were it not for the fact that the bulk of the bark sent from Ceylon during the current season has been very inferior in quality and deficient in alkaloidal strength. Hence the actual shortage in the bark supply must be calculated as fully two million pounds at the least.

In the present position of bark, therefore, we have a good reason for an advance in the price of quinine, but a reason that might not have had full weight but for the change of policy on the part of the foreign manufacturers. This is indicated by the recent action of a leading German manufacturer, who has been systematically bearing the quinine market, for the supposed purpose of getting cheap bark, in withdrawing offers to sell for future delivery at former prices.

In our own market which has been stagnant for a long time, so far as speculative transactions are concerned, the position is more flattering to holders than it has been at any time for months past, and the inference is plain that prices must advance, unless there is a radical change in the governing conditions. The large consumptive demand above referred to has absorbed so much of the surplus supply, which was estimated at between seven hundred thousand and a million ounces at the beginning of the year, that a liberal calculation places the present available supply at not over two hundred thousand ounces, and this is so held that it could hardly be used to prevent a natural improvement in prices.

From this survey of the position an advance in the price of quinine would appear to be inevitable, yet the quinine market is such an uncertain one, and so much money has already been lost by speculative ventures in it that a much stronger showing would appear to be requisite to inspire the confidence in the class of investors who have been accustomed to dealing in this commodity, and stimulate a strong upward movement in prices.—*Oil, Paint and Drug Reporter*.

THE DEPRECIATION OF CUPREA BARK.

The enormous reduction in the price of cinchona bark during the last six or seven years is sufficiently notorious, but it is not without interest to particularise the fact by one or two graphic illustrations, taken at random from recent public sales of South American bark. There are at present in the London warehouses, and probably also in other trade centres, large accumulations of Cuprea, "Soft Colombian," Pizaro, and other American barks, which have been stored there between 1880 and 1884. When these barks arrived here, the owners preferred to stock them, the market at that time being in an extremely sensitive condition, and prices generally declining though an early return of the good times was still widely anticipated, especially when it became known that one of the largest importers in London, through whose hands passed nearly all the Cuprea bark a variety which, though in reality not belonging to the cinchonas at all, may be classed with these

for practical purposes), was maturing a gigantic scheme for "cornering" the article. At that period the South American barks still gave the tone to the market, forming, in 1880, 58 per cent.; in 1881, 77 per cent.; and in 1882, 72 per cent. of our total imports; and sudden fluctuations in price were greatly assisted by the restless political state of the South American Republics and the small number of great importers on this side. An idea of the importance of the shipments of Cuprea bark may be gathered from the fact that in 1881 over 15,300,000 lb. of this variety were exported from the port of Baranquilla alone, a quantity almost equalling that shipped from Ceylon during the season 1885-6, the most productive one on record in the island. And when, in 1884, a large London firm of importers of South American bark came to grief, their stock of Cuprea alone is said to have reached over 5,500,000 of lb. Much of this bark, especially the parcels imported when the first exploited woods became exhausted, is of a rather low average standard; but nevertheless these importations represent an enormous aggregate of alkaloid. For years the owners of these barks seem to have witnessed the depreciation of their stock without being able to come to the resolution to sell off as best they could, and only within the last few months have they begun to freely place their bark in auction, and thus it becomes easy to estimate with some precision the difference which their policy of waiting for the never-returning tide of prosperity has made in the balance at their bankers. Let us take two typical examples from last Tuesday's sales, and compare the offers then made with the prices which the parcels might have realised some years ago; for it is notorious that offers from five to ten times as high as are now eagerly accepted for the very same lots were at one time scornfully refused. A parcel of 146 serons of Cuprea bark, imported in April 1882, was sold this week at 3*d.* per lb. The average weight of each seron being 140 lb., the owners obtained for their lot, roughly speaking, and not calculating allowances, discounts, &c., 255*l.* When this bark was landed, six and a half years ago, they might easily have sold the same parcel at 2*s.* 6*d.* per lb.—then an average market value of Cuprea bark—thus realising 2,550*l.* Add to this 250*l.* for six and a half years' loss of capital, warehouse charges, &c.—a very moderate allowance—and one can easily imagine the feelings which the original importers (supposing the parcel to be still in his hands) must have experienced upon examining the sale account of the transaction. Another instance is that of a parcel of 116 serons of "Soft Colombian" bark, imported in March 1883, for which the owners last Tuesday refused to accept 3*d.* per lb., a decision which they may have reason to regret. When this bark was landed the price of the mark which it bears (horse's head over B) was from 3*s.* to 3*s.* 3*d.* per lb., and the lot would have approximately cleared 2,400*l.* On Tuesday about 200*l.* might have been obtained for it—a price which would, perhaps, have defrayed the accumulated charges and the estimated allowance for interest, but very probably may now not again be obtainable. Well might the auctioneer, in offering some of these goods, refer to the "dreadful sacrifices" the owners were making, a remark, by the way, received with unsympathetic merriment. But it cannot be overlooked that the owners had had ample warning of the coming *debâcle*, and the general verdict will no doubt be that it served them right. In 1879 and 1880 the price of this "Soft Colombian" bark attained its zenith from 5*s.* to 6*s.* 6*d.* per lb. being then obtainable for the best qualities; but even in 1883, when the parcel above referred to was imported, the value was already falling at an ominous rate, and it was then well enough known to those who followed the bark market closely that in another three or four years the reign of South American barks would have altogether passed away. At present all appearances would seem to indicate that the most advisable course for the holders of

the South American barks, the accumulations of which still fill room after room in the gigantic warehouses at our docks, is to liquidate their goods in the promptest possible way, and to accept the inevitable without incurring further risks for the sake of a few pounds.—*Chemist and Druggist.*

CULTIVATION OF THE ORANGE TREE IN SPAIN.

REPORT BY CONSULAR AGENT LOWENSTEIN, OF GRAO, ON THE CULTIVATION AND PROPAGATION OF THE ORANGE TREE IN THE PROVINCE OF VALENCIA.

The study of the orange tree has determined by analysis that its ashes give the following result per cent, viz:—

COMPOSITION OF THE ASHES OF THE FRUIT.

Constituents.	Mineral manure	Compost.
	Per cent.	Per cent.
Potash	20.15	15.28
Soda	10.22	12.14
Lime	30.12	30.24
Magnesia	9.02	8.10
Phosphoric acid	20.04	18.24
Sulphuric acid	1.08	4.14
Silicic acid	4.50	5.82
Oxide of iron	4.25	4.75
Loss	0.62	1.29
	100.00	100.00
Ashes of the fruit ... per 100	3.57	3.48

COMPOSITION OF THE TRUNK, BRANCHES AND LEAVES.

Constituents.	Trunk & branches	Leaves.
	Per cent.	Per cent.
Potash	14.15	10.18
Soda	10.67	10.82
Lime	31.57	41.22
Magnesia	10.64	6.54
Phosphoric acid	18.82	19.47
Sulphuric acid	4.89	4.53
Silicic acid	2.82	5.48
Iron and loss	6.44	1.76
	100.00	100.00
Azoe of the leaves ... per 100	1.57	1.60
Ashes of the leaves ... do.	6.32	6.20

The orange trees analysed were from Alcira (Valencia); some manured with compost and others with mineral manure. The proportional difference noted between the assimilated nutritive principles is not to be wondered at, for, as has been observed, this varies with the same plant according to the nature of the soil and the manure employed.

DISEASES OF THE ORANGE TREE.

The development of disease in the orange trees is greatly contributed to by atmospherical phenomena, various insects, and parasitical plants, as also the neglect or limited knowledge of the cultivators.

The effects of cold, snow, humidity, dews, frosts, hail, wind, burning rust, chlorosis or yellowing of the leaves, and withering are as follows:—

COLD.—This commences by destroying the tender shoots of the trees, followed by the drying up of the blossom, after which takes place the disorganization of the fruit and afterwards that of the leaves, branches, trunk, and finally roots. Crevices open in the branches, which bend and turn black, the leaves wrinkle, roll up, and die; the flowers become blackened and disorganized; the fruit loses its brilliancy, dissipates its odorous principles, loses its juice and becomes bitter, falls off the tree and rots, or if the cold has not been very intense the fruit is half frozen and remains on the tree till the following spring.

SNOW.—This injures the trees, both from cold and its weight. Should the storm be heavy and the fall great, this bears down the branches and in many cases breaks some. As regards the cold occasioned by it, this does not always do harm, but when it does so it is very frequently confined to the young shoots. Should the weather be fine both before and after a snow-storm, the cold water produced on thawing produces its effects on the young branches, for which reason no time should be lost in shaking all the snow off them before nightfall, for should it be condensed on them, the harm occasioned would be of much greater importance. The system of placing heaps of damp straw at fixed distances between the trees, so that on setting said heaps on fire in order to obtain a smoke between the sun's rays and the trees, has produced a magnificent result. If after snowing the weather continues threatening, or there be heavy clouds floating about, neither the trees nor the fruit will suffer any harm, although the thermometer might be below zero.

HUMIDITY, DEWS, AND FROST.—An excess of humidity in the atmosphere during the fecundation of the blossom generally produces bad results, especially in such places where the ventilation is limited, should the temperature at night decline to any extent. Frost with an east wind occasions a deal of harm, but should the wind be from the north it is not so bad. Little that is economical can be availed of in large orchards, but in reduced ones the harm is lightened at small cost by availing of certain materials for shelter, of little value, which in certain districts are plentiful.

HAIL.—This causes a deal of damage to the fruit. Should the storm be of short duration and the wounds occasioned by it be of slight profundity, these will soon heal up and everything continue well, but certain black stains will remain which reduce the value of the fruit. Should the storm be heavy, it completely destroys the orange, which quickly enters into a state of putrefaction.

WIND.—This exercises its influence on the orange trees in two different ways, viz., by its force and by its temperature, the injury caused being greater or less according to the position in which the orchards may lie. North, north-west and west-northwest winds are the most dangerous in certain places on account of their temperature, for as a rule they dry up the extremities of the branches exposed to their influence, besides which the shoots of certain species become unsound. Those that cause most harm in the South of Europe, by reason of their impetuosity, are the south, south-southwest, and south-southwest, according to the position of the valleys. All these winds come with puffs of extraordinary strength, and destroy the branches unable to resist them. The only remedy in these important occasions is to cut off everything that has been destroyed and dried up. With the object of partially avoiding these misfortunes, the custom of producing trees of shortened growth has of late years vastly extended.

THE BURNING AND RUST.—The disease known as burning is due in great part to the too abundant dew that fall here, which are evaporated with an excessive rapidity by a burning sun. To the same cause may be traced the disease vulgarly called "rust," or a class of mildew on the leaves of the orange trees. This manifests itself on the fruit by a red stain, which, as it increases, becomes much darker and finishes by disorganizing the pulp and rotting the fruit. The cleaning and pruning of the trees is the best known method against this evil.

CHLOROSIS.—In chlorosis or yellowing of the leaves, and also the withering, are generally attributed either to the superabundance of humidity in the soil, to an excessive quantity of branches having but a free ventilation, to the want of iron in the earth, to a species of torpor in the absorption of the mineral matter existing in them, and so the alteration of the roots, if old. The remedy to be employed to combat this evil is distinct according to the cause by which it is produced.

—*Victorinus Eusebius' Gazette.*

(To be continued.)

THE LABOURING CLASSES IN SOUTHERN INDIA.

[As so very large a proportion of the labour employed in Ceylon comes from South India, the following details are specially interesting. It will be seen how the influence of Ceylon on Madura is acknowledged.

—Ed. T. A.]

THEIR MATERIAL CONDITION.

On the 17th August last year the Government of India called for reports on the material condition of the lower classes of the population in India. The Madras Government replied on the 27th May last. In a resolution under date the 19th instant, the Government of India remarks:—

The Madras report is preliminary and the enquiry will be continued. The opinions of the district officers are not supported by concrete instances, but in many cases they reflect the views of men who have for years observed the conditions of agricultural life in Madras. The conclusion of these officers which is concurred in by the Board of Revenue and by the Madras Government, is that no considerable proportion of the population suffer from a daily insufficiency of food in ordinary years.

In the *Ganjam* (area 3,106 sq. m., population 1,603,301) district, though the income of agricultural labourers only just meets their expenditure, they have enough to eat.

In *Vizagapatam* (area 3,477 sq. m., population 1,790,468), the Collector says, the agriculturists live miserably, and cannot afford a sufficiency of food. With two and sometimes three meals a day a cloth to cover himself and a hut to live, "the labourer is probably the poorest creature in the world." But as pointed out by the Madras Government the Collector admits that the inhabitants are an unusually sturdy and muscular class of men, and this is hardly compatible with a want of food. Further, it may be added, that two or three meals a day is quite up to the average; that clothes in the Madras climate are superfluous; and that the hut is the customary and traditional house of the peasant.

In *Godavari* (area 6,525 sq. m., population 1,780,613), there is no deficiency of food among adults.

In *Kistna*, (area 8,471 sq. m., population 1,548,430), prosperity is universal.

In *Nellore* (area 8,739 sq. m., population 1,220,236), the Collector denies any insufficiency; but the Civil Surgeon supports the insufficiency dictum on the ground that criminals always increased in weight after they had been in jail some time, and that a large number did not get sufficient food to develop their muscles to their full extent. The Board of Revenue remarks that the Madras jail dietary is the most liberal in India, and that the hard labour of a prisoner in jail is by no means such hard work as that undergone by the labourer in the fields. This question of rise in weight during incarceration is one of some importance and has been noticed in other provinces. Mr. Crook, in the North-Western Provinces, suggest that a newly-admitted prisoner has just passed through the ordeal of arrest, and that he has probably been remanded more than once or marched about the country after a Magistrate in camp. A man like this naturally loses weight in the interval between arrest and conviction. The Indian convict is not in solitary confinement: he is a cultivator, he is free from the labour and anxiety of field watching at night. He is promptly attended to for the most trifling ailments. Dr. Lethbridge, Inspector-General of Jails, Bengal, also considers that the deep anxiety and often distress which precede conviction cause loss of weight. It may be added that a convict does not indulge in tobacco and opium. Mr. Bridgitt, a missionary, says, that the lower classes in Nellore do get enough to eat, and that they save money.

In *Cuddappah* (area 8,745 sq. m., population 1,121,038), except from the 24th April to 20th June, every one gets regularly more than enough and even in the slack season there is little demand for work.

Great weight is attached by the Board and the Government to the opinion of Mr. Nicholson, Collector of Anantapur (area 5,664 sq. m., population 699,880). He says, that the people in a strong

physique; that the birth rate is high; that in 1885 when relief works were opened few were attracted to them; and that the labouring classes depleted as they were by the famine of 1876-78, always and everywhere in ordinary time find a sufficiency of the food to which they are accustomed.

In *Bellary* (area 5,602 sq. m., population 726,275), it is thought the standard of comfort has risen.

In *Kurnool* (area 7,785 sq. m., population 709,305), Mr. Benson, who is working at an analysis of the district, says that there is no large class of persons pinched for food from year's end to year's end, and that there are few beggars or loafers.

In *Chingapat* (area 2,842 sq. m., population 981,381), the Collector thinks the mass of the people live from hand to mouth, and in adverse seasons are seriously hampered. But the Government of Madras believes that the condition of the people has improved in a marked degree within the last ten years.

In *South Arcot* (area 4,873 sq. m., population 1,814,738), employment is obtainable without difficulty at wages that give the labourer a sufficiency of food.

In *Tanjore* (area 3,654 sq. m., population 2,130,383), there is no sign of widespread poverty.

In *Trichinopoly* (area 3,561 sq. m., population 1,215,033), wages are high, food is cheap and the appearance of the people is most prosperous.

In *Malabar* (area 5,765 sq. m., population 2,365,035), the people are stout, well grown, well nourished and muscular, "Children swarm and are as plump as partridges."

In the *Nilgiris* (area 957 sq. m., population 91,034), "the proportion of the population who suffer from want of food is extremely small—as small as it is in any part of the British Empire."

In *Tinnevely* (area 5,381 sq. m., population 1,699,747), the diet is sufficient to maintain a high degree of physical efficiency. The people are well-fed and have a margin for superfluities as is evidenced by the habitual use of ornaments by men and women of the common cooly caste.

In *Canara* (area 3,902 sq. m., population 959,514), the monsoon has never failed and scarcity is unknown.

In *North Arcot* (area 7,256 sq. m., population 1,817,814), the Collector in a burst of rhetoric suggests that grinding poverty is the widespread condition of the masses, and two missionaries state that many poor people who though they do not actually starve, go through life on insufficient food.

In *Madura* (area 8,401 sq. m., population 2,163,680), the labouring classes are very well off and the condition of the district is no doubt good, owing to the large amount of emigration to Ceylon and the Straits Settlements.

In *Coimbatore* (area 7,842 sq. m., population 1,659,690), no one need starve who can or will work.

On the whole it may be said that in ordinary seasons the lower agricultural classes generally get throughout the year a sufficiency of food, that is food enough to maintain them in bodily health and strength and in full efficiency for labour.

In *Coorg* (area 1,583 sq. m., population 178,302), which is so favourably situated from a climatic point of view, there has not been that scope as in other Provinces for an enquiry of the kind indicated by the Government of India. In this province there are no causes at work which tend directly to bring about a condition of widespread poverty or distress of a chronic character, and the condition of the ryot is, on the whole one of advancing prosperity, which in individual cases can be frustrated only by thriftless and reckless habits among the people.—*Indian Agriculturist*.

CINCHONA IN JAMAICA.

The Superintendent of the Jamaica Cinchona Gardens, in his report for 1887, states that some cinchona trees have been dying off that year. On investigation, it was found that the bark at the junction of stem and root has been injured, and that in consequence the mycelium of a fungus had pene-

trated between the bark and wood. The bark had become loosened on the roots, and decayed away. It is probable that the injury was caused by the wind during the last hurricane. It would be difficult to detect such injury at first, but probably an early application of the remedy prescribed for the orange trees would have saved the trees. Trees which are too far gone to save should be taken up by the roots and barked. The bark may be stored after thorough drying, for mildew does not affect the quantity or quality of the alkaloids when the bark is cured.—*Oil, Paint and Drug Reporter*.

[The dying off in Jamaica is what we have been so familiar with in Ceylon.—Ed.]

BANANAS.—A young Salvadorian, with the dark eyes and inky hair of his country, talked to a reporter the other day about the Central American banana tree. The tree is 2½ to 3 feet in circumference at its base. Its tapering fibrous stem, without a branch, is from 10 to 15 feet in height. The fibres, separated by a thin pith, are as long as the body of the tree. These fibres are used in Salvador, just as they are taken from the tree, as shoestrings and as cords for all purposes. The natives use them largely for bridle reins and lariats. The raw material costs only transportation to the ropewalks. Each banana tree bears in the twelve months of its existence only one bunch of fruit, but from two to ten trees spring from the roots of the one that has fallen. In Salvador the bunch of bananas is worth fifteen cents, and the dead tree nothing. A cordage factory or paper mill or coffee sack maker, were not the dead trees numberless, would give for each tree ten times the value of the fruit it has produced. Split, dried and packed, the bodies of the banana trees might be shipped profitably to the United States, but there is no reason why some enterprising American should not take them in hand.—*Guatemala Star*.

TRADE IN DOG SKINS.—Mr. Edgar, the Commissioner of Customs at Newchwang, in Manchuria, in the last Chinese Customs Yellow-book, referring to the trade from that port in robes and mats made of the skins of dogs and goats, says it is generally supposed that dogs are picked up promiscuously wherever they may be found straying, destroyed, and their skins sold to dealers. This, however, is not the case, for although the business may have had its origin in this way, it is now as systematically carried on as sheep-farming. There are thousands of small dog and goat farms dotted over Manchuria and the eastern borders of Mougolia, where from a score to some hundreds of dogs are annually reared on each farm, and where they constitute a regular source of wealth. A bride, for instance, will receive as dowry a number of dogs proportionate to the means of her father. It is probable, says Mr. Edgar, that in no other part of the world are there to be found such splendid dog skins for size, length of hair, and quality, the extreme cold of these latitudes, where the thermometer registers 30° Fahr. below zero, developing a magnificent coat. It is difficult to understand how the dog farmer can afford with profit to rear the animals when the price of the robe is taken into consideration. For one full-sized robe, say 80 in. by 86 in., at least eight animals are required. Putting the price realised at 14s. 6d. for a robe, this would only allow about 1s. 10d. per skin, including the selection—for the skins must match in colour and length of hair—and cost of sewing. The animals are generally strangled in mid-winter, but not before they are eight months old, and then the skins taken in a frozen condition principally to Moukden and Chinchow, where they are cured, assorted, and made into robes, mats, &c. Last year the robes are said to have been decidedly inferior in quality. The reason given is that orders went forward too late, and the farmers, waiting till they had news of some demand, kept the animals alive until their winter coats began to fall off. The value of the trade from Newchwang last year was about £40,000, against nearly £60,000 the previous year. The decline was due to depreciation in value and a decreased demand from the United States.—*Journal of the Society of Arts*.

PRODUCTION OF TEA IN MATALE EAST :—
CHIEFLY FROM OLD COFFEE AND
CINCHONA LAND.

We and our readers are indebted to the planter who has furnished the following figures, which, in the face of most of the land being old and some of the tea of inferior jät, are abundantly encouraging:—

ESTATE, MATALE EAST.

Statement of green tea leaf plucked and made tea in lb. per acre from 1st Nov. 1887 to 31st Oct. 1888.

Fields No.	Acres weeded.	Acres in tea.	Green leaf lb.	Made tea	
				25-25 per cent.	lb. per acre.
1	12	12	13,848	3,492	291a
2	28	27	20,852	5,258	191b
3	12	12	6,706	1,691	141c
4	33	33	33,242	8,382	254d
5	41	40	45,395	11,447	286e
6	22	21	11,601	3,682	175f
7	15	15	10,817	2,728	181g
8	34	30	16,853	4,250	142h
9	43	40	39,482	9,955	249i
	240	230	201,796	50,885	321
		Young Tea	1,101	1,036	
Total tea despatched			205,900	51,921	

REMARKS.

- a New land, all pruned within the year, poor jät.
- b Old coffee land, partly pruned, do "
- c Old cinchona land, all pruned within the year, poor "
- d Old coffee land, not pruned, chiefly good "
- e Do do do do "
- f Do clearly all pruned within the year, poor "
- g Do all pruned within the year, fair "
- h Do poor jät, not pruned do "
- i Do all good jät.

NOTE.—The average age of the tea is 3 to 4 years. The weeded acreage includes 10 acres of timber trees planted 5' by 5'. The above pretty clearly demonstrated the all importance of good jät. The increase in the yielded in field No. 5 is accounted for by its having all been manured within the last 2½ months of the year. When manuring was commenced Nos. 4, 5 and 9 were in lb. per acre, within 3 lb. of each other, No. 5 being the lowest.

The above figures are very interesting, but it has been remarked to us that the case against poor jät was not quite conclusive, the first case of poor jät giving the highest return of all. But there is no doubt of the superiority of good jät. Only if people have a lot of inferior jät (over an appreciable acreage by itself, and not scattered among good), experience shows that wonderful results can be obtained by low pruning, down to 6 and even 4 inches. This and cattle manure have given splendid flushes from Darjiling China.

NOTES ON PRODUCE AND FINANCE.

(H. and C. Mail, Nov. 30th.)

A Manchester correspondent of *Globe* utters a grovel against what he calls the inequitable system of medicinal Indian teas of average quality, which are sold at 10s. He says that India has a system of investing without having a right of the value of its only really good article into India, and therefore the injustice arising therefrom has not been felt in any great extent, but there naturally will be a great outcry arising if the reputation of coffee is on a par with other. Last week we learned that the weight of the contents of tea chests, referring to three separate lots, varied at various points. And though the gross weight of each package was 1 lb. or more over the rated weight, yet every package contained less tea than was charged for, and the total

amount absolutely short in the ten chests was over 17 lb. Now, there can be no two opinions as to whether that sort of thing will be submitted to, and it seems to me that the only way to have matters put on a more satisfactory footing is for every buyer of Indian tea to have the contents of each package turned out and carefully weighed, and where the weight does not correspond with the quantity charged for, demand redress from those parties by whom the tea is invoiced. I mean, of course, where the packages are received in such good condition that no claim can be made against carriers. It seems to me that most tea buyers are satisfied if they find gross weight correct, and do not trouble to tare the empty packages; yet that is the very thing they ought to do, unless they are prepared to pay for wood or lead at tea price; and not many in these days will be so disposed.

Manufacturers of tea machinery should keep an eye on Natal. The American Consul there has taken a great interest in the tea-growing experiment in that Colony, and he has reported to his Government thereon.

As the tea from India and Ceylon is all pure, tests are not necessary, but if any one wishes to try a test on some inferior China tea, a Russian analyst has been kind enough to write to the papers giving the following:—Take a pinch of tea in a glass, pour upon it a little cold water, and well shake it up: pure tea will only slightly colour the water, while a strong infusion is quickly got from the adulterated or painted leaf. Now boil both sorts separately, and let them stand till cool, and the difference between them will be most marked. The false tea will become still stronger after long standing, but will remain transparent, whereas the pure tea will become muddy or milky. This last appearance arises from the tannic acid, which is a natural property in pure tea, but which in artificial tea is entirely absent.

DRUG TRADE REPORT.

LONDON, November 29th.

When the announcement was first made that the firm of Messrs. Lemaire & Rivers Hicks, the bark importers, was involved in financial difficulties, we announced that a satisfactory settlement was likely to be arrived at. We are now glad to be able to report that Mr. Rivers Hicks, as will be seen from page 748, has emerged from his difficulties in a manner reflecting great credit on his personal character, it being specifically stated that misfortune overtook him through no fault of his own. It also transpired in the course of the proceedings that Mr. Hicks might have escaped, or at any rate materially lessened, his liabilities by selling a number of shares held by him in an Indian cinchona estate, but refrained from doing so from the honourable motive, that, as chairman of the company, he would be injuring it by selling out his own shares, thought the step might have personally benefitted him.

ANNARU.—A small parcel of cake annatto from Ceylon was shown today, but no bids were made for it. Twenty-six baskets old and dry Brazilian roll were again offered and bought in at 1s to 1s 3d per lb.

CARDAMOMS were again sparingly represented at the auctions, but the 77 packages shown comprised several of fair and good quality. Holders were not at all anxious to sell their supply, and only a small proportion was therefore disposed of, which realised an advance of fully 3d per lb on good qualities. Ceylon-Malabar, good pale heavy medium round 2s 5d; fair pale pump 2s 4d; medium to bold pale, 2s; and round mixed 2s 3d; brownish and slightly mouldy round 1s 8d; very small warty round 1s 3d per lb. Mysore, very good pale medium to bold 3s; fair medium pale round and rather shiny 1s 11s; medium specky yellow 1s 10d; brownish long and plump, round 1s 9d; fair small brownish 1s 5d; small dark and spat 9d per lb. Good Wild Ceylon were bought in at 1s 3d per lb nominally. Seed, ordinary to good

brown, sold at 1s 3d to 1s 7d per lb. The exports from Ceylon for the month of October have been, in 1888 16,451 lb; 1887, 24,946 lb; 1886, 13,651 lb.

CINCHONA.—Ten cases fine heavy cultivated Bolivian Calisaya, in long silvery quills, were bought in at 1s 10d per lb; 1s 6d being suggested as the price. Of 17 packages Guayaquil, a certain portion sold at 1s 8d to 1s 9d per lb for fine O.Z. quills, and at 10d down to 5d per lb for ordinary qualities of flat Calisaya. Thirty serons, imported via Havre, were mostly bought in, one lot fine bright hard selling at 2s 3d per lb. The exports of cinchona bark from Java are officially reported as follows:—

	July 1st to September 30th.		
	1888	1887	1886
	½ kilos.	½ kilos.	½ kilos.
Private Plantations	916,363	864,391	444,692
Government...	148,479	170,295	168,550
Total...	1,064,842	1,034,686	613,242

QUININE.—The present week has been one of the quietest on record and in the absence of any transactions of importance prices remain virtually unchanged, though the B. S. agents today quote 1s 5d per oz and say that they have reason to expect higher prices.

THE AMERICAN MARKETS.

NEW YORK, November 14th.

QUININE.—Though the cable reports of last week's bark sales were more favourable for the position of quinine, the only effect there was the expression of somewhat steadier views, without, however, material difference in the price. The demand does not increase nor quicken in the least, all speculative interest being suppressed for the time, buyers following the plan of providing only such quantities as absolute wants make necessary. In this way Gold and silver is quoted 33c, Brunswick 34c, and B & S 35c to 36c; the latter, however, is scarce.—*Chemist and Druggist.*

TYPHOID FEVER AND CHOLERA.—Broward, one of the first authorities on the subject in the world, declared that outbreaks of typhoid fever are due, in ninety cases out of a hundred, to drinking water. Also, that the most distinguished experts have come to the conclusion that contagion by the air which we breathe is most rare. Pasteur and his disciples have failed to establish a single case of chicken cholera contagion by the air. M. Chamberlain goes so far as to deny altogether the presence of pathogenic microbes in the air.—*Chemical Trade Journal.*

SUCCESSFUL CARDAMOM-GROWING.—The best districts for cardamoms in Ceylon are undoubtedly to be found on our north-east ranges, and although taking the planting country as a whole, the cultivation of this spice seems to have fallen off of recent years, attention being so generally given to tea, yet we are glad to hear of fresh and prosperous clearings in the favorite quarter referred to. The Mysore variety has proved so well-suited to the climate and soil in one case where clearings of 10 to 15 acres are judiciously opened that at 3½ years old, a crop of 500 lb. per acre has been gathered; a year later over 500 lb.; and this last year, about 600 lb. per acre. The latest shipment was sold at 2s 5d a lb.—a rate which enables cardamoms to beat all but the very best tea fields. Curiously enough, we learn that the boxes of cardamoms are carried in to Kandy for 30 miles on the heads generally of Sinhalese villagers who are fond of the work, because apart from paying them well—three days' pay for the journey—it is the sort of independent employment that suits them. In this way the cardamoms leaving the estate the morning of one day catch next morning's train for Colombo and the minimum of risk of injury to the cardamoms, is thus incurred.

THE EAST BORNEO PLANTING COMPANY, LTD.—At a meeting of shareholders of this Company in Hongkong on the 3rd instant, Hon. B. Layton, Chair-

man, it was carried to buy a second block 5,000 acres selected land, making in all 10,000 acres, and the following account of the work done was given:—

Mr. Abrahamson—With regard to the work done, Mr. Chairman, I may state that two large coolie-houses and a godown have been built, and the manager's house is in course of construction. I may say the managers when they came to the place were far more sanguine of the likely results of the Company's planting than I was, and fully bore out my idea that the soil was quite equal to, if not better than, what they have been working on in Deli. The Company have been fortunate enough to secure the services of a capable manager in Mr. Schuit. He is a Dutch planter who has been managing properties that have always paid a very high dividend. Mr. Schuit's idea is that we can produce tobacco in quantities that will pay very well. At the outset we have had a splendid labour force, and, what is more important than anything else, the health of the coolies is first-rate. I estimate that at an expenditure of from \$50,000 to \$60,000 we shall reap from 800 to 1,000 piculs tobacco, the value of which may be taken from \$80,000 to \$100,000. The reports concerning the sale of last shipments of tobacco from the country are also highly satisfactory, although this tobacco did not reach the market in a satisfactory condition owing to its having been mildewed. It averaged at the rate of R1.26, Deli tobacco being at the rate of R1.11, and as Deli tobacco pays handsomely at that ours ought to pay much better, especially as the cost of production with us will be 20 to 25 per cent less than at Delhi. Altogether I consider our prospects are satisfactory (Applause).—*Overland China Mail.*

COFFEE IN EASTERN JAVA.—The *Soerabaische Courant* of 19th Nov. contains a note, dated 16th Nov. which we translate as follows:—

"Malang Coffee Reports.—A couple of months ago the anticipations for the 1889 crop were very bright. The first blossom, which came out early, set well; the weather was so favorable, that good hopes were cherished for the succeeding blossomings. The too prolonged drought however did much damage to the plantations, and to add to the disaster a couple of severe wind-storms were the unwelcome cause of reducing somewhat the crop estimates on several estates. On the Southern Mountains, the Karvi and the Ardjoeno, the first showers of rain fell in the second week of this month, on the meroe and the Tenger mountain somewhat earlier, but still too late to do any good to the existing crop. One or two secondary blossoms are still expected. In some places the larger part of the blossom has not set to form fruit, in others the greater part of the blossom is withered. The trees which last year produced the most will some of them give very little and others only a moderate outturn. Leaf-disease is more visible in the younger than in the older gardens, but does not cause anxiety. Supplying and planting will soon be commenced."

THE RUSSIAN COAL AND COKE INDUSTRY.—The basin of the Don is ready to provide fuel of every kind, whether for industry or domestic purposes. The coalbeds have been worked since 1860, during which year the first railway, that of Kursk-Charkow-Azove, was made through the southern basin. The annual production of the basin of the Donetz amounts to about 100 millions of pounds (36 lb. = 1 pound), about eight-tenths of which were forwarded by railway. In 1888, however there were, it appears, 180 million pounds disposable, without including the quantities which still remain at the pit's mouth, and those which are intended for consumption in the neighbourhood. The progress in the manufacture of coke is important. In nine of the coal pits of the region, 192 kilns are in working order, and 52 are being built, so that the manufacture of coke will soon occupy 244 kilns. In 1887 there were produced 8,470,000 pounds of coke, whilst for the present year it is estimated that the product will exceed 12 million pounds. If we allow that a fixed quantity of coke demands the employment of 50 per cent. more of coal, then this industry absorbed in 1887 about 17 million pounds, and will require in 1888 25 million pounds.—*Chemical Trade Journal.*

PETROLEUM AS A FUEL FOR ESTATES.

A home correspondent who has on former occasions obliged us with his views as to methods desirable of adoption to meet the growing scarcity of timber fuel in the neighbourhood of estates, has further written us relative to our recent suggestions for the use of petroleum either to supersede or supplement that failing supply. He tells us that consequent upon reading what we have written on this subject he has made inquiry in quarters likely to be possessed of experience in the burning of mineral oils, and that he has besides read with care some of the most recently published articles on the subject, especially those which have dealt with the various forms of furnaces designed for their combustion and with the results obtained in practice by the steamers which ply around the shores of the Black Sea. According to him, it is apparent that it is only about those shores that the use of petroleum is preferred to coal as a fuel. The reason for the preference there, is evidently not far to seek. The extensive oil wells at Baku and of the Caspian levels furnish a supply which makes the steamer service of the Black Sea independent of the coal supply for which Southern Russia has always had to rely on the import from foreign countries. In the event of hostilities with any other naval power, independence of such a supply must be vital to the utility of the Tsar's Black Sea fleet. Hence every endeavour has been made by the Russian Government to foster the substitution of petroleum for coal, not only in its ships of war, but also in the large fleet of mercantile steamers which find employment upon the coasts of the southern maritime boundary of that country. But the results of a few years' working with the new fuel have now been made known, and that knowledge certainly does not seem to recommend the use of mineral oil for fuel except under such peculiar conditions and for the special objects named above. The greatest ingenuity, our correspondent informs us, has been shown by a perfect host of inventors in the endeavour to devise some description of furnace which shall economically burn petroleum, but hitherto without a result likely to cause it to widely supersede the use of coal. Most of these furnaces are complex in character, and the use of them, our correspondent thinks, would be absolutely prohibited on our estates by their liability to get out of order, by the incessant watchfulness they require, and by the highly skilled labour their repairs necessitate. Even with all the advantages possessed by a great maritime power like Russia, with the aid of highly skilled engineers always available, it has been found that the cost of petroleum as a fuel is quite one-third greater than that of coal.

The proposition is therefore submitted to us as to whether, assuming first cost in the countries of supply to be about equal in the cases of coal and mineral oils, the difference of bulk for shipment and transport upcountry is likely so to affect cost of delivery as to turn the scale economically in favour of the latter fuel. Great doubt is expressed to us that it can do so. Coal admits of transit in bulk, while oil must be carefully packed and its storage and transport must be always subjected to restraints imposed by authority, for both of which reasons coal will probably admit of much cheaper delivery than oil. If, our friend advances, the cost of burning mineral oil even in the locality of its production is one-third in excess of that of coal, it scarcely seems likely that there can be any saving to be effected by its use in a country so distant from the source of supply as is Ceylon. Our correspondent thinks that coal

will possess the advantage even in cost as compared with oil even if we leave out of consideration the simpler methods for its combustion which are available, and it is needless to point out how desirable it is that estates should be worked as far as possible by methods which do not demand the constant service of highly skilled labour.

Apart from this matter of cost, our correspondent asks whether we have altogether overlooked the possible effect of the fumes of burnt petroleum on the delicate flavor of a product so liable to absorb tainting smells as is tea. He tells us that even the most perfect furnace yet designed for the burning of petroleum or other mineral oil has been found inadequate to prevent disagreeable fumes extending to some distance around. Unless our estate furnaces could be situated at some very considerable distance from the drying-rooms, it is held to be certain that the aroma of our teas would become very seriously affected by these fumes, and we should certainly say that it would be found almost impossible in practice to have the furnaces for heating and drying air for tea curing located at any distance from our estate factories. All these reasons our correspondent believes to forbid the hope being reasonably entertained that petroleum can ever be available to meet the deficiency that is apprehended in our supply of wood fuel. The latter is the fuel which must always prove best adapted for tea preparation, and he counsels us not to abstain from continual exhortation to the planters to be earnest in their endeavor to meet a possibly short supply of it in the future.

THE AGRICULTURAL RESOURCES OF NEWFOUNDLAND.

A very favourable account of the agricultural resources of Newfoundland is given in the Ontario "Globe" by the Hon. John Macdonald, who has recently visited the Island. The fishing industry has been at a very low ebb lately, and this led Mr. Macdonald to make some inquiries as to the desirability of the people turning their attention to agricultural pursuits. That there is a large area of very fertile land in Newfoundland appears to be generally admitted, and it appears that the climate, though unpleasant, is less severe in winter and less hot in summer than the greater portion of the Dominion of Canada. When the first official handbook was published in 1881, there were only 47,000 acres under cultivation, out of 5,000,000 acres said to be suitable. No wheat or barley worth mentioning was grown, and only about 5,000 bushels of oats were produced. No doubt there are considerable tracts of land on which oats could be profitably cultivated; but the island is more suitable for grass and fodder crops than for cereals. The growth of the former crops is wonderfully luxuriant. Mr. Macdonald passed over rich fields on which clover had been growing in abundance for more than thirty years without manure and with no sign of soil-exhaustion. On asking why great accumulations of manure were left to be wasted, Mr. Macdonald was assured by a farmer that the manure did not need manure, and that if applied to potatoes it would cause them to be smothered with clover. As a stock-breeding country, he considers that Newfoundland has great advantages, one of which is that it is 3,000 miles nearer to Europe than the ordinary district of Canada, now a great stock-producing country.

CEYLON TEA AND ADULTERATION.

Part of a Memorandum of Ceylon, Ready for the House of Commons, The Editor, Ceylon, 1888.
 On the 11th inst. the subject of Ceylon tea was discussed by Mr. Wm. Martin Lusk with further reference to the information regarding the case *Rex v. Ellis* instituted

under the provisions of the Merchandise Marks Act.—I am, sir, yours faithfully, A. PHILIP, Secretary.

London, 30th Nov. 1888.

A. Philip, Esq., Secretary, Planters' Association, Kandy.

Dear Sir,—In continuation of my letter of 16th instant, I have the pleasure to forward report of the further proceedings at the Mansion House yesterday in the case against Mr. A. J. Ellin. I also enclose copy of broker's reports on

1. The 1 lb. packet of Bungalow Tea bought from Messrs. Loe & Son, Woking, by Mr. W. R. Wainwright.

2. The $\frac{1}{2}$ lb. packet of tea, priced at 6d and with some label as above, handed to me by Messrs. Loe & son after the first hearing.

The other $\frac{1}{2}$ lb. packet handed to me by Messrs. Loe & Son and priced at 7 $\frac{1}{2}$ d was marked only "Pure Ceylon Tea," without the small letters below, and contained a very good Ceylon pekoe souchong valued by the brokers at 1s 3d in bond.

The result of the brokers' examination of these two packets made me think it unwise to follow the case further unless compelled to do so. And as soon as I heard from Mr. Wainwright that he was unable to trace how the 1 lb. packet came into his hands, I communicated with Mr. Gray who advised a withdrawal of the summons.

Accordingly our solicitor called on Mr. Ellin's solicitors with the result that they produced to me undoubted evidence that on the day in August last when the packets of the blend were made up by Mr. Ellin for Messrs. Loe & Son, the teas blended were:—

160 lb. Dikoya mark 2,032 ex "Rohilla"

40 lb. Darragalla " 176 ex "Bulna"

40 lb. China Tea " 5,753 ex "Prometheus"

I was a little surprised to learn that the teas were blended *by hand* on a table, and I suppose that the large proportion of China tea found in the 1 lb. packet must have been due to uneven blending.

Under the circumstances I trust that the settlement arrived at will be considered by your Committee satisfactory.

I have felt a great responsibility on me in the matter and have looked only to the effect of our action on the sale and distribution of Ceylon teas.—I am, &c., (Signed) WM. MARTIN LEAKE.

P. S.—I shall send you by next mail copies of correspondence *re* new Crane Wharf case.

REPORTS ON TEA, BUNGALOW BRAND, IN ONE POUND PACKET PURCHASED AT WOKING.

13, Rood Lane, London.—Mixed leaf both in colour and size, the tea contains but very few ends, the liquor is soft, and has a decided China character. It is our opinion, that the tea is a mixture, largely composed of the China variety.—(Sigd.) GOW, WILSON & STANTON.

41, Mincing Lane, London, 28th Sept. 1888.—The "Bungalow Brand" is certainly not pure Ceylon, but contains a considerable proportion of *China Kaisow*; whether the balance is composed of *Indian* or *Ceylon* we cannot say; the strong but rather coarse favour of the Kaisow predominating to such an extent as to overcome that of any other tea it may be blended with. This sample is of good strength, but of poor quality; an Indian Pekoe Souchong at 8 $\frac{1}{2}$ d per lb., gives a much better liquor.—(Sigd.) WILSON, SMITHETT & Co.

REPORTS ON QUARTER-POUND PACKET "BUNGALOW BRAND" TEA PRICED AT 6D.

13, Rood Lane, 22nd Nov. 1888.—Concerning the packet which was open when you handed it to me and which is stated to be pure Ceylon tea blended with Assam tea. My opinion is that the tea contains a proportion of China tea, which is noticeable in the flavour of the liquor. My opinion is that this quarter-pound sample does *not* contain China tea of so coarse a nature or so large a quantity as the large one-pound packet, and that the two teas *not* identical. I do not think this is as clear a case as the former, although I think there is no doubt that the tea is partially composed of China Tea; but you have not so strong a case.—I am, &c., (Signed) A. G. STANTON, GOW, WILSON & STANTON.

W. Martin Leake, Esq.

41, Mincing Lane, 21st Nov. 1888.—We have compared the second sample ($\frac{1}{2}$ lb. packet) of the "Bungalow Brand" with the original one in three different liquorings and have on each occasion, especially on the first, found it superior in cup; we fully believe it to contain some China tea, but it has not the same strong Kaisow flavour as the sample from the original one pound packet. Different samples from the same blend might no doubt give liquors varying to some extent, but the difference in the two samples under review is so marked, that we can scarcely believe them to be from the same blend.

(Signed) WILSON, SMITHETT & Co.

W. Martin Leake, Esq.

COSTA RICA AND CULTIVATION.

The state is divided into three departments—the eastern, western and that of Nicoya. Each of these, again, is subdivided into districts, each with an alcaide in charge of local affairs. Costa Rica's area is 26,000 square miles, and her revenue approximates \$2,000,000 per annum. Some 38 years ago the Government granted to M. Lafond, the French consul general, a tract of land extending from the Gulf of Dulce, on the Pacific, to Baco del Torso, on the Caribbean Sea, for the purpose of opening a route between the two oceans. That across the isthmus, by San Juan river, along part of the frontier line of Costa Rica, is so far opened that steamers ply in connection with others on the Lake of Nicaragua. There is also a railroad on the Atlantic side into the interior.

The Casdillera of the isthmus, which is really the connecting link between the Andes of the south and the Sierra Madres of Mexico, leading on to the Rockies of the north, throws off numerous spurs on either side, running diagonally across this little republic, giving the surface a continuous alternation of abrupt heights and sudden depressions, interspersed with extensive forests and barren tracts. The primary range bristles with an unparalleled series of volcanoes, extinct and active, including Osasi, Votas, Cartigo, Irazu, and a dozen others of that "burning gorilla" that surrounds the Pacific. From the summit of the central table lands, on a clear day, both the Atlantic and Pacific oceans can be distinctly seen.

In all parts of Costa Rica, except along the burning shores, the climate is salubrious, subject neither to excessive heat nor cold, and experiencing few changes, except from the wet season to the dry. It is therefore admirably adapted to agricultural purposes, especially in the table lands and well watered valleys. The remarkably fertile soil is capable of bringing to perfection most northern fruits and cereals, as well as those peculiar to the tropics; but nothing is cultivated but coffee, sugar-cane, rice, tobacco, Indian corn, and a very little wheat. The yearly export of coffee now amounts to more than 200,000,000 pounds—though that berry was first introduced into Costa Rica less than 60 years ago. Previous to that time the people were very poor, and it is only since the culture of coffee has been so extensively carried on that they have attained to anything like prosperity.

The woods of Costa Rica are particularly valuable including tulip, aloe, rose, and other rare varieties, besides vast forests of mahogany, cedar and India-rubber trees. Cocoa, sarsaparilla, wild indigo and various dye woods are among the indigenous products. Pearls are found on the western coast, below Nicoya Bay, and an extensive trade is carried on in their shells. An excellent quality of tobacco is raised, which is chiefly shipped to Nicaragua, though some of it goes to British markets. Costa Rica—"the Rich Coast"—derived its name from the once wonderful gold mines of the eastern mountains, and much silver and copper are also known to exist. But for more than 100 years little attention has been paid to the mineral resources—for to wrest from mother earth the treasures she has hidden requires, as a rule, more enterprise and money than these people possess.—*Cor. "Massachusetts Spy."*

NEW USES FOR PARAFFIN.

In Burma the use of earth oil as an alleviator of pain in rheumatism has long been known. It is also used by the Burmese for children, in cases of colds and coughs, by rubbing their heads with it. Paraffin is said to stimulate the growth of hair in Europe, but the Burmese have seldom occasion to use it for this. Miss Gordon Cumming, in a recent communication to a home paper, calls attention to the important medical properties of paraffin in various diseases:—

"There seems no end to the multitudinous fashions in which mineral oils come to the aid of man. And yet how very recently have these uses been discovered. But a few years have elapsed, since the days when the Red Indians of North and South America, the tribes on the shores of the Caspian and the Red Seas—in short, primitive man, wherever dirty, black grease, oozing through dark mud, smoothed the water of sluggish streams—brought their sick, suffering from cutaneous and rheumatic diseases, to be healed. Accident and experience had taught them this value of that floating oil; but that was all.

"The so-called fire-worshippers (attracted by the weird flames which sometimes played on the mountainside, kindled by the spontaneous ignition of gases) had indeed erected a temple at Baku where the sacred fire was fed direct from the soil; but it had not then occurred to enterprising men that the oil which floated on the lake, and which when ignited by means of blazing straw produced such fairy-like illumination could be turned to account; nor could the wildest dreams of the earliest oil prospectors on the Caspian or in the United States have conceived the possibility of a commercial success so amazing as that of the oil traffic which has been developed within the last thirty years. Paraffin has well nigh supplanted the various oils and greases previously in use throughout the whole world; even to the remotest Hawaiian, Tahitian or Fijian Isles, where the cocoa-palm has ever afforded the purest of vegetable oil.

"Nor as an illuminant alone has the kindly earth-oil been turned to us. It has revealed such precious properties of soothing and healing, such excellence as lubricating oil for machinery, it has yielded such varied preparations of vasine for wounds and for toilette purposes, that merely to catalogue these would be a task. And now to all previous services another is added—perhaps the most domestic of all. Mineral oil offers to be the ready benefactor of that great body of women whose lives are embittered by the ever recurring toil of the wash-tub.

"It seems that by the addition of a very small amount of mineral oil to boiling water and soap almost all manual labour in clothes-washing may be dispensed with, for at the end of half an hour the clothes will be found so clean that little further is required save to rinse them in two or three hot and cold waters. The smell of paraffin is not pleasant during the boiling process; but after the final rinsing no trace of it (it is said) remains, and the clothes are easier to iron. Henceforth all temptation to use deleterious bleaching powders must surely be at an end; for nothing can be cheaper or simpler in its application than this use of mineral oil which has no injurious effect whatever on any animal or vegetable fibre. It is equally good for linen, cotton or woollen clothing; it does not affect the colour of cotton dresses or of flannels of any of the ordinary 'fast colours,' and it can be used with equal success in a copper or iron boiler, wooden or earthen-ware tubs. The only precaution to be remembered is to make sure that no careless sloven shall carry her bottle of inflammable and explosive oil to the fire-side to pour the oil direct into the boiler, but shall measure the requisite quantity into a cup at a respectful distance.

"The recipe recommended by a lady in a leading northern paper (the *Standard*) and which has called forth a chorus of thanksgiving from many grateful householders who find it a perfect success is to fill an average-sized boiler—say fourteen gallons

—with water adding half a pound of soft soap, and when this is thoroughly boiling, pour in $\frac{1}{2}$ table spoonfuls of paraffin. Then put in the clothes in the ordinary course, boil for half an hour, then lift them out and rinse in several waters. Add a little more water, soap, and paraffin to make up for evaporation and what is lifted out with each set of clothes. Thus washing is done with a marvellous saving of toil, time, temper and soap. The same amount of work which by the ordinary method requires the whole time of two women for two days, can thus be done and done well, by one woman in eight or nine hours.

"It appears, however, that a yet more excellent way has already been discovered and widely practised both in America and New Zealand. There only the best kerosine is employed, as being far more free from smell, and, moreover, for that reason it can be added as soon as the soap is dissolved—while the water is still at a low temperature. Consequently flannels and blankets, which must on no account be boiled may be placed in the boiler and thoroughly steamed. If paraffin is employed, then the boiling mixture must be lifted out into tubs, where the flannels can be washed by hand while the linen is being boiled in the re-filled boiler. Thus no time is lost."

Miss Gordon Cumming has overlooked one point inasmuch as she seems unaware that paraffin exists commercially in two forms: one a solid, and the other commercially so called, a volatile mixture of light hydrocarbons, in which benzines and naphthalines are largely represented; both these substances are more usually obtained by the destructive distillation of shale-oil, although they can, in modified forms, be obtained from earth-oil and crude kerosine. However, common kerosine can be similarly used for washing purposes, and with all due deference to the writer, is so used in the Australasian colonies, where its employment is by no means the novelty suggested. —*Rangoon Times*.

RUSSIAN PETROLEUM.—It is said that the producers of petroleum in the Caucasus propose to ask for the construction of a second line on the Trans-Caucasus Railway, and for the prohibition of foreigners from buying a farming petroleum-producing lands in Russia.—*Indian Agriculturist*, 1st Dec.

CULTIVATED LAND IN INDIA.—The twenty-fifth and twenty-sixth tables of the new Indian Statistical Abstract contain some information of special interest at the present moment in regard to the area of British India actually under cultivation, the area at present uncultivated, which might be cultivated, and the proportions of the different crops. The total acreage of India according to the Survey Department is 480,667,994 acres. Deduct 116,615,483 acres, the area of the feudatory and tributary States and of other districts for which agricultural returns are not obtainable, and with which the figures do not deal and we get 364,051,611 acres as the area of British India for agricultural purposes. Of this less than half or 152,834,640 acres is actually under cultivation including 22,725,391 acres of current fallows. Of the 166,492,458 acres which is uncultivated rather more than half is fit for cultivation, and the remainder is not available for that purpose, so that an area of 80 millions of acres in British India still awaits the husbandman. The area under forests which is not included under either cultivable or uncultivable land is 40,185,729 acres. The distribution of crops was as follows:—Rice, 23,111,662; wheat, 19,883,040; other food grains including pulse, 71,439,218; tea, 226,112 (almost wholly in Assam); cotton, 9,852,654; oil seeds, 7,678,382; indigo, 1,034,889. It thus appears that there is practically unlimited scope so far as area is concerned for the increased cultivation in India of crops which are mainly intended for export such as wheat, cotton, indigo, tea, coffee, &c.—*Indian Agriculturist*.

PLANTING IN FIJI :
A FORMER CEYLON PLANTER ("A. J. S.")
ON FIJI :

SUGAR—COFFEE—FRUIT—TEA—CARDAMOMS—LABOUR :

A CONSOLIDATED ORDINANCE WANTED IN FIJI—

SIR J. B. THURSTON, A GOOD GOVERNOR—
THE "T. A."

Fiji, 21st Nov. 1888.

DEAR SIR,—It's now some time since I last addressed you, and many changes have taken place in the Government here, but I cannot say that the planters have much benefited during the time. The planting interest is at as low an ebb now as it was some years ago; in fact, I may say it is worse, as many men have left the group and hardly any new plantations have started, if I leave out one or two exceptional cases where wealthy Companies have started sugar. I will first of all start off with the Sugar industry which takes prominence, not only on account of the large sums of money which have been embarked in the industry, but also on account of the cultivated acreage. Well, sugar most certainly has not turned out the Eldorado expected. When the Sugar Conference was sitting in England great things were talked of: prices will go up, the bounties will be knocked on the head, &c. Instead of this, prices are still low, and I very much doubt whether any sugar estate has as yet paid. One Company long ago entirely suspended operations on the Navua, after having spent a great deal of capital. Three others, in different parts, have been in liquidation, and have been taken over. Two or three small Companies and private planters have shut up altogether. The great Company, of course, is the well-known C. S. R. Co. of Sydney, who not only have large extents under cane, but have most of the planters growing cane for them. Whether their operations have paid, or would pay, if they had not a refinery to send their coarse sugar to, I don't know. Sometime ago they got out new machinery to add on to their already immense mill on the Rewa. This was not erected and was re-shipped to the Colonies after having lain idle a considerable time.

Three months ago I took a trip and visited the Bau district where the Company have started a large mill and have a lot of cane which they intend irrigating, as the climate is a dry one. For this purpose a practical man has been engaged, who formerly did similar work at Honolulu. During my visit the works were in active progress. I saw the dams which had been made and the drains and canals being cut to bring the water from different creeks some distance off. Water was also pumped up from the river to treat the cane along the banks. The works will naturally cost a deal of money, but will not be nearly so expensive as I thought they would be, before I paid the place a visit. Should the irrigation scheme turn out a success, I am inclined to think that the dry parts of Fiji will give better and more paying crops, than the wet Rewa and Navua where sugar has, up to the present, been mostly tried. The planters on the Rewa, who are planting for the mill, are getting more per ton this, than they did last year. It is to be hoped they will be able to make it pay as they have, for a long time past, most of them, had hard and anxious work with very little or no returns.

Coffee, as I predicted a long time ago, has turned out a failure. Fiji cannot now boast of a single coffee plantation. All have gone to the wall.

The Fruit industry has gradually assumed large proportions. Many thousands of bananas are shipped monthly, and most of them go to the

Sydney market, where, if they arrive in good order, they meet with a ready sale. The Melbourne market has lately been tried properly and shippers are in hopes, although the voyage takes longer, of being able to get their bananas there in good order. If they succeed, and the Melbourne people take to the bananas as well as the Sydney folks, it will give the fruit industry an immense fillip. Pineapples are also shipped, and a good many go to New Zealand where they sometimes fetch good paying prices. Coconuts also go forward in large numbers. Fast steamers, properly fitted up, are required if the fruit industry is to be a thorough success. When in Sewa, I was watching bananas being shipped and stowed away. They are packed away in the hold one on the top of another, in a very haphazard way, and not at all gently handled, and how any of the bunches can arrive in decent order in Sydney or elsewhere is a puzzle to me.

Tea, by all accounts, is doing well in Vanua Levu, as well as in Taviani. Another estate is being started in Taviani by the same Company who own the Alpha estate. The tea is much appreciated in the colony and hardly any other kind is sold. The importation of Indian and China teas this season will be very small. New Zealand takes large quantities and the Fiji teas fetch at auction, in the Colonies, as good prices as Indian and Ceylon, in fact in some cases, better.

Cardamoms at Alpha this year had a very large crop on them; but most unfortunately nearly all was lost in the hurricane which occurred in February last. This has happened now twice. In March 1886 a good crop was utterly destroyed.

LABOUR—This all-burning question is still in a most unsatisfactory state. Men, Polynesians, are not so hard to obtain, but they cost too much altogether. Why the Government do not tackle this labour question before anything else, and put it on a satisfactory footing, I can't imagine. The yearly cost of the men wants to be considerably reduced before the country can go ahead and compete with others. The principal point is the introduction of the men. They generally cost now about £15 a head.* This is absurd and steps ought to be taken to reduce it to about half. There was a great talk a few months ago of getting the steamer to bring them over from a depôt which was to be formed on one of the Hebrides islands, but up to the present, with no practical results. A good many of the useless allowances made to the men might easily be done away with, and this would materially help to reduce the yearly cost, and what is badly required is that all the innumerable old ordinances should be at once done away with, and one suitable for the present condition of the colony introduced. One great injustice we suffer under I consider, and *i. e.* that Polynesians when imprisoned, are not made to make up their time at the end of their indentures the same as coolies have to do. The planter, therefore, if one of his Polynesians has served, we will say, twelve months in jail out of the thirty-six he is indentured for, not only loses all the work the man might have done, but is also out of pocket whatever the proportionate sum the man may have cost to introduce and return to his island. This is most unjust, and wants altering at once. If a labourer, for some fault or crime, is imprisoned, he ought to make up his time.

Sir J. B. Thurston who has been a great many years in Fiji and who was formerly our Colonial

* Let the Fijian colonists be thankful that their insane desire for annexation to Victoria did not succeed. The artisans who rule that Colony would have prohibited the use of native labour, at rates which would pay planters.—ED.

Secretary, is, as you know, our present Governor. For a conscientious hard worker and one who thoroughly understands all the requirements of Fiji and the natives, no better selection could have been made. From the speeches he has made he seems to sympathise with the state of the planters, and is anxious to do what he can to ameliorate matters. There is no doubt he has many great difficulties to contend against, and the principal one is want of money, the exchequer being in a bad way; but, nevertheless, we shortly hope to see some practical good done to help on the agricultural industry.—The *T. A.* is often read here by visitors, and many go away saying they intend taking it in. The new is an improvement on the old form. The work is certainly full of most interesting and valuable information for all planters, and one I should recommend them to regularly take in. There are more subjects I should like to write about, viz., land, native question, &c.; but my letter has already reached a length you will be grudge in your paper I fancy. Wishing old Ceylon a prosperous year,
A. J. S.

DRUG TRADE REPORT.

LONDON, December 6th.

WEST AFRICAN CINCHONA.—Among the bark offered for sale at the London auctions this week was the unusually large consignment of 50 bales from the island of St. Thomas, in the Gulf of Guinea, Western Africa. This bark which generally reaches us via Lisbon, has been met with at the auctions several times before now, but never, we believe, in so large a quantity at any single sale. On Tuesday 5,253 lb. were offered, the average weight of each package being about 1 cwt. The bark appears partly in thin twigs and partly in dull orange-coloured thinish quills, about 8 in. to 10 in. in length, covered with a slightly silvery epidermis, and bearing a very great resemblance to the "Huanoco" bark from South America. It is obtained from succirubra-trees, which have, however, slightly altered some of their characteristics in the African climate.

We understand that the St. Thomas plantations have now arrived at a state of maturity which will enable their owners to send the produce to the market in much greater quantities than they have done hitherto.

CINCHONA AUCTIONS IN 1889.—At the London public sales on Tuesday it was decided to hold the first cinchona auctions in 1889, on Tuesday, January 15th, and from that day forward on every alternate Tuesday. The Amsterdam sales for 1889 have been fixed at January 17th, February 21st, March 21st, May 2nd, June 13th, July 18th, September 5th, October 3rd, November 7th, and December 12th, always on Thursdays following the London auctions.

CINCHONA.—At the public auctions on Tuesday a somewhat larger quantity was offered than that shown at the preceding sales, but the assortment was of an inferior character. The catalogues included:—

	Packages	Packages
Ceylon bark ...	1,415	of which 1,180 were sold
East Indian bark ...	209	" 152 "
Java bark ...	71	" 62 "
South American bark	1,725	" 595 "
West Coast African bark	50	" 50 "
Total ...	3,470	" 2,039 "

The auctions opened with a very weak tone, and although a little more spirit was put into the bidding soon afterwards, there cannot be said to have been any substantial improvement as compared with the preceding sales, the unit remaining practically unchanged at 24 to 24 1/2 per lb. The following are the approximate quantities of bark purchased by the various buyers at the auctions:—

	Lb.
Agents for the American, French, &c., works	140,000
" " the Messingh & Amsterdam works	110,000
" " the Auerbach works	63,855

Messrs. Howards & Sons ...	36,822
Agents for Messrs. Jobst & Zimmer ...	25,600
" " the Brunswick works ...	16,969
Mr. Thos. Whiffen ...	16,288
Sundry buyers ...	18,883
Total quantity sold ...	420,260
Bought in or withdrawn ...	178,577
Total offered ...	607,837

The moderate supply of East Indian barks did not offer many parcels of great value. Original Crown chips dull and small, brought 3d; renewed chips from 6d to 1s per lb; Succirubra, dull twigs and shavings 2 1/2d to 3 1/2d; good bold shavings 5 1/2d to 6 1/2d; a few cases fair mossy druggists' quill sold at 9d per lb. Of Java Bark a poor assortment was partly disposed of weak and damaged split, partly bold red quill 3 1/2d to 5d; very ordinary damaged pulpsty ditto 1 1/2d per lb; good Crown branch chips 7 1/2d; dusty ledger twigs 3d to 3 1/2d per lb. Fifty bags West Coast Africa Bark sold as follows:—Succirubra, quill, fair bright hard, about 3/4 to 1 foot long 5 1/2d to 6d for sound; 5d for damages; broken and mixed with branch 3d to 4 1/2d; twigs 2d to 3 1/2d; very low damaged 1 1/2d per lb. Of South America Bark, large parcel of Cuprea, Hard Pitayo, and Soft Colombian were offered for sale, most of these being of old import, and having been offered very many times before already. None of these parcels were sold, Cuprea being generally held at 4d to 4 1/2d per lb, Hard Pitayo at 3d to 3 1/2d, and Soft Colombian at 2 1/2d to 3 1/2d per lb. But of the Calisaya quills from the Bolivian and more or less irregular, and 10d to 1s per lb for good strong silvery quill. One small bag fine but damaged flat red bark sold, with good competition at 8s per lb.

COCAINE.—One of the German manufacturers (Schering) has suddenly reduced his price to 16s 3d per oz. for bulk, in consequence, it is said, of reports from South America stating that another manufacturer has commenced making crude cocaine there. However this may be, the other German and the English makers have not yet followed suit, and quote 18s 6d per oz. for B.P. hydrochlorate. Messrs. Böhringer & Sons inform us, with reference to the reported synthetical manufacture of cocaine that long before the publication of this process they have carried out the same idea in practice, though under a somewhat different form, for which they applied for a patent. The expectation that this discovery will greatly influence the price of cocaine is erroneous, as the amount of the alkaloids in question is too small.

CUBERS firm here at unchanged prices. The latest Java mail advices state that the long-prevailing drought there has greatly hindered the growth of the berries. The next crop will be very late, and if the rainy season should not set in shortly, a considerable proportion of the next crop will be totally lost.

QUININE.—There were rumours early this week of transactions of some importance at an enhanced price: Brunswick quinine in bulk being reported sold at 1s 4 1/2d per oz. for March-April delivery, and on Tuesday we heard that another 50,000 oz. of the same brand had changed hands at 1s 4d per oz. Smaller sales of B. & S. quinine, also second-hand at 1s 4d per oz. are likewise reported; but we should think there would be some difficulty to sell at that price. All the other makers' quotations remain unchanged.

THE AMERICAN MARKET.

New York, November 24th.

QUININE continues dull, at least so far as regards the sale of quantities, the business passing being wholly of a jobbing character. "Good and best" grades in a small way at 32c for large bulk, Brunswick 33c, and B. & S. 34c.

THE DUTCH MARKET.

AMSTERDAM, December 4th.

The next public sales of Java cinchona will take place on December 13th, and will comprise about 100

tons, in 1,748 bales and 142 cases, of which about 36 tons are Government cinchona. The quantity of manufacturers' bark amounts to about 122 tons, with an average of 4.3 per cent sulphate of quinine, or about 188,000 oz. 9.7 tons contain 1 to 2 per cent of sulphate of quinine; 20.3 tons, 2 to 3 per cent; 27.0 tons, 3 to 4 per cent; 29.5 tons, 4 to 5 per cent; 13.3 tons, 5 to 6 per cent; 14.9 tons, 6 to 7 per cent; 7.3 tons, 7 to 8 per cent; total 122 tons. The druggists' bark (about 31 tons) consists of:—Succirubra: quills 120 cases, 8 bales; broken quills and chips 145 bales; root 55 bales. Calisaya: Schukkraft quills 17 bales; broken quills and chips 24 bales; Anglica, broken quills and chips 73 bales; root 15 bales; Javanica, broken quills and chips 16 bales; root 4 bales; and the manufacturers' bark of:—Ledgeriana quills 22 cases; broken quills and chips 993 bales; root 241 bales. Officialis, broken quills and chips 22 bales; Hybrids, broken quills and chips 131 bales; mixed bark 4 bales; total 122 cases, 1,748 bales.—*Chemist and Druggist.*

DELI NEWS.

COOLIE TROUBLES.—On the 30th November, a detachment of troops, 45 strong, left the chief town for the Bekalla estate, to restore order among the Chinese coolies on the plantation. They had assumed a threatening appearance against the manager. By noon the same day, the ringleaders were in jail. The troops returned soon after.

THE PLANTERS' COMMITTEE.—At the end of last month, the Planters' Association at Medan unanimously passed a resolution empowering the managing committee to take any further steps that may be necessary to foster Chinese immigration into Deli. It is only by union among the planters that success can be achieved in the recruiting line. The establishment of direct coolie immigration for China requires a tough fight on ground that must be gained inch by inch. It is only unanimity among the planters than can bring them to the desired goal.

SUGAR GROWING.—On the East coast of Sumatra, especially in Deli, tobacco cultivation has been the exclusive pursuit of the planters, who care nothing for the danger of putting all their eggs in one basket. Lately, now that the soil continually cropped for tobacco begins to show signs of exhaustion, some of them have cast about for other means to gain a living by cultivation. Sugar growing has come into favour as a possible standby, but the depression of trade in this article does not hold out encouraging hopes to parties desirous of embarking in the venture. An experimental plantation would settle doubtful points once for all, and prove whether or not the soil of Deli lends itself readily to a new departure of the kind suggested, but the difficulty lies in finding any planter willing to risk capital in such a novel undertaking.

THE RAILWAY.—The Deli railway works continue to make headway. A heavy consignment of materials for it recently arrived at Belawan from Singapore in the steamer "Hydra." The "Hebe" also has brought a further supply of materials. At Singapore, so heavy of late has been the arrivals of articles for the Deli railway that shipping facilities for conveying them to their destination fall short.

BORNEO.—Deli finds not only British North Borneo but also the Netherlands portion of that island coming into prominence for tobacco growing purposes. In Holland enterprise has distinctly set in that direction. The other day a company was started to carry on plantation operations for growing tobacco and other products in the residency of S. E. Borneo. The capital has been fixed at one million of guilders.

Tobacco Auctions.—A trade journal at Bremen assures its readers that there is every prospect of 20,000 bales of Sumatra tobacco being offered at the periodical auctions there next year. Negotiations were in progress for securing larger quantities. At that city, a company has been formed under the style of the Bremen Sumatra Association, to start tobacco plantations in Sumatra, and carry on trade in the produce of the same. The capital will not go beyond 200,000 marks.—*Straits Times.*

NOTES ON PRODUCE AND FINANCE.

The London Wholesale Tea Dealers, Association object to the average net weight system of weighing Indian tea, and a letter has been addressed to the Secretary of the Indian Tea District Association, giving notice of the determination of the present system at the end of the current season. It is notified that all teas imported after June 1st next will be taken with the ordinary gross and tare.

There is much grumbling in the spice trade. It is said that pepper is mixed with dirt, and that there is much loss of weight in spices between the time when they are landed and delivered. This was brought prominently under the notice of the trade by Mr. D. R. Harvest at the public sales recently, when he said that "he considered the matter to be of a pressing nature, for the losses on the re-weights of spices had for some time been continually increasing and the evil had now become a very serious one for most of the buyers in that room. It was not necessary for him to point out the extent of the loss or how it had arisen, but those questions would doubtless be gone into if his resolution should be adopted, and he moved "that a committee of four dealers and four brokers be appointed for the purpose of taking into consideration the serious losses now sustained by buyers on the reweights of imported goods."

The deliveries of cinnamon in London for the past eleven months have been at a materially diminished rate as compared with those in 1887 having been only 6,420 bales, against 8,750 bales: and while the landings have been quite on an equality with the imports in 1887, the present stock exhibits a decrease of about 400 bales, all Ceylon. The periodical sales last week were of usual extent for this time of the year, having comprised 2,680 bales Ceylon, of which above 1,000 bales consisted of second sorts, and meeting a steady demand, nearly the whole of the supply was taken off; prices, though ruling somewhat unevenly, being, if anything, rather in favour of the sellers, especially for the medium and commer grades, and for the parcels sold under the hammer ranged from 5d to 8d for fourths, with superior at 11d; also at from 6d to 1s for thirds; 7½d to 11½d for seconds, with extra fine at 1s 2d; and at 8d to 1s 1d for firsts and superior, besides finest plantation growth at 1s 3d to 1s 5d; and broken (in twenty-seven boxes) at 6d to 7d per lb.—*H. & C. Mail, Dec. 7th.*

THE PETROLEUM SITUATION.—Capt. J. J. Vandergrift, President of the United Oil and Gas Trust, in an interview with a Pittsburg *Commercial Gazette* reporter furnished some highly interesting information about the condition of the oil trade in Western Pennsylvania and also the future of the Ohio petroleum trade. He claims that by next year there will not be enough oil produced in this State or left in stock to supply the demand of consumers, and for that reason the world will have to go elsewhere to get its full supply. The Captain also positively asserts that the Standard Company is not operating its refinery at Lima, and that the oil found in Ohio cannot be refined so as to compare with the Pennsylvania product.—*Chemical Trade Journal.*

PLANTAINS.—There are few descriptions of wood which yield a large return for any labour bestowed than plantains. A single tree has been known to produce fruit weighing 70 to 80 lb, whilst half this amount is said to be the average yield. According to Humbolt whilst 1,000 square feet of land will yield only 462 lb. of potatoes or 36 lb. of wheat, 4,000 lb. of plantations can be produced in a shorter period of time. When ripe almost three-fourths of the fruit consists of water, the remaining parts consists of sugar, and two parts only of gluten or flesh-forming substances. Like rice, then, the plantain is not by itself a perfect food, requiring the addition of some nitrogenous material, as pulse, fish, or meat.—*Indian Agriculturist.*

Correspondence.

To the Editor.

DAVIDSON'S NEW "SIROCCO'S."

5th Dec. 1888.

Sir,—Coming from a planter, the following details concerning the latest improvements in "Sirocco Tea Driers" will doubtless be interesting to many of your readers, to whom I am tempted to offer them, owing to their intrinsic importance, which was made so forcibly manifest to me at the first trial any planter has been permitted to witness, viz. at the Sirocco Works, Belfast, last week.

It is somewhat rash, perhaps, to pronounce a verdict based entirely upon one's own unaided eyes; but in a matter of this kind; but, speaking solely for myself, and with all modesty, it is permissible to say that, I think that the last thing in "Siroccos," viz. the introduction of the "Down Draft" principle, is the most important innovation which Mr. Davidson has introduced since he first brought out his original "No. 1 Sirocco."

Before dealing with this new departure, however, it is as well to briefly notice the great improvements recently made in the "T Sirocco" type of the old "Up Draft" principle. Apart from all the new minor variations in type, we have henceforth to deal with variations in principle also, which is for the future divided into the two major divisions or classes, the "Up Draft" (or old principle) and the "Down Draft" (or new principle). At present there is only 1 type of the "Down Draft." Of the old "Up Draft," there are several types as your readers are aware, such as the original "No. 1 Sirocco," the "T Sirocco" and its different sizes, &c. The latest improved "Up Draft Sirocco" consists in such a blending of the "No. 1 Sirocco" with the "T Sirocco," as produces a novel "T Sirocco," called the "Side-Drawer," embodying in itself all the advantages of its two parents, so to speak, whilst the least convenient features of both are omitted. In the new "Side-Drawer," the external shape is that of the "T Sirocco." Instead, however, of the "T Sirocco" arrangement of the trays sliding through from end to end of the drying chamber, these are now placed in sets of 4 trays as drawers, one above another, as in the "No. 1 Sirocco," and they draw out independently of each other at the side of the drying chamber over the back part of the stove. This arrangement necessitated an alteration of the position of the "by-passes," these instead of being partially outside the drier as in the original "T Sirocco," are now arranged vertically between the different tiers of trays. The chimney's position is no longer at the back of the drier, but alongside the fire-door. The advantages gained by these alterations are self-evident, but may be briefly summed up as follows:—The drier now requires a much smaller pit, whilst a free and open head-room for the stoker is still maintained. The highest tray is in contact with the floor, 9 in. from the floor-level, thus affording, with all the others, complete facility for rapid, easy, and convenient inspection. The form of the drier is more compact, whilst still retaining the advantages of the "by-passes" for conducting hot air to the upper trays. Last, but not least, the risk of scorching a lot of the trays when, from any cause, a delay occurred in removing the last tray in the original "T Sirocco" type is completely avoided. The stove is provided with all the most recent improvements, and its life has been immensely extended by the new cast-iron tubes. I trust I have now justified the opinion set forth above, that this Sirocco embodies in itself all the advantages of its parents, and affording the least convenient features of both.

Getting now to the "Down Draft" principle, I will first refer to the "Down Draft" principle, the original "Down Draft" principle, which was first introduced by Mr. Davidson in the year 1860, and which was then called "power" or "up-draft," in the sense of a power-driven fan, but in his latest improvement of his draft upside down, and now draws the hot air

downwards from above through the tier of 8 trays, enclosed in the specially constructed drying "chamber" of his new "Down Draft Sirocco." A description of the apparatus itself I will not attempt, and for two reasons. In the first place, most of your readers will doubtless have already received an illustrated circular which sufficiently describes the apparatus; so a description here is a waste of force. In the second place any verbal description would fail to do justice to the extreme simplicity of this Sirocco. Suffice it, that it is most simple to erect, being sent out in large sections, only requiring joining together; and it is as simple to work as the "No. 1 Sirocco," with the additional convenience, that the man working it never feels any radiated heat from it. Mark, I do not say that it is easy to work, as that would be incorrect. It is simple, yes, as simple as would be wished, but its appetite is such that to feed it to the capacity thereof will tax two coolies to the full powers of endurance which could reasonably be expected in them for a whole working day. It has 8 trays, and as fast as two coolies can properly spread the charge of green leaf on these, so fast almost will it dry them off! It takes 8 minutes from the insertion of a tray of rolled leaf at the "inlet port" below, to its withdrawal as dry tea at the outlet port above. It will be hardly necessary to call attention to what this rapid rate of firing means in the matter of improved quality of outturn. When tea is not thus very rapidly dried, allowance in the "fermentation" has to be made for that much "fermentation" which will certainly go on during the drying, until it is checked by the heat. Considerable uncertainty is attached to this, as the condition of the leaf, and of the temperature of the drier &c., &c., have to be taken into account, and that part of the "fermentation" which takes place in the drier not being under actual observation, is open to serious variation and inequality. Mr. Davidson started upon the accepted view, that an ideal tea drier must check "fermentation" in the shortest possible space of time, thus allowing the change of colour in the leaf during "fermentation" to be kept under actual observation, outside the drier, to the last moment before checking it; and further, that this power of immediately checking "fermentation" must be at the same time free from any risk of scorching or over-firing. Starting with this ideal in view, he believed that a comparatively low temperature was necessary to avoid the risk of over-firing. To get the requisite rapidity in firing, he therefore resolved to rely upon the speed of the current of air employed to remove the damp absorbed by the warm air. The result is this new Sirocco in which the temperature is never allowed to rise above the safe limit of 240°, and in which the leaf is nevertheless completely dried in 8 minutes. Planters do not need to be reminded, that if leaf is completely dried in 8 minutes, "fermentation" must have been checked in a very much less time still. Hence, it is not going too far, to say that Mr. Davidson has attained his ideal, and as most will agree to his definition of the ideal, the advance he has made will be pleasant news, if the results with actual tea tally with those obtained at the trials with thoroughly sodden, chaffed or chopped straw which I witnessed, and which trials quite bore out the estimate given on the illustrated circular to which I have already alluded. That estimate, I take it, is for average weather; in dry weather, so far as one can judge on this point, it may be exceeded; in very wet weather it may possibly hardly be reached. On the whole, it seems a fair and reasonable estimate, so far as one can calculate here. The suitability for "Burrhead" loose packing I saw tested with actual small-leaved tea; and 200 lb. were passed through in 80 minutes, thoroughly well finished, although the temperature actually at the bottom of the chamber was 240 degrees—hence, so far as final firing is concerned, the estimate on the circular could not have been exceeded. The power is so arranged that it can be stopped at any moment, and the tea can be more than borne out, as the temperature was not up to full limit, the leaf too was only about the size of a leafy broken pokon, and yet the work was turned

out at the rate of about 5 maunds per hour and the aroma was perfect. Not a grain of dust or broken "tips" (*challoni goori*) was lost, as even the very few grains which get drawn down through the meshes of the lowest tray are caught in the bottom of the cool portion of the drying "chamber," whence it can afterwards be easily removed through a door for the purpose. For "final firing" the trays, which are of the usual sirocco size and pattern, hold 6 lb. of tea each.

In this sirocco, the fresh trays are inserted at the bottom and rise step by step to the top as each new tray is inserted, being finally withdrawn from the top. This arrangement, coupled with the down draft (which, striking the top tray first descends through the whole tier of 8 trays and then is ejected by the fan) causes the warm dry air to strike the upper and drier trays first, and to pass away exhausted after having done its duty, without an atom of the damp from the lower fresh trays ever reaching any of the drier trays above them—an advantage which might fairly be considered another attribute of an ideal drier. The heat is most evenly distributed over the trays, and the top tray can be inspected at any moment most easily, without shutting off the suction of the fan, or interfering in any way with the drying; nor is a particle of leaf ever at any time ejected from the tray port whilst even "final fired," dusty tea is being thus inspected; nor is the leaf, or tea, on the trays, disturbed in the slightest degree by the action of the "draft." Besides the actual thrusting in and the withdrawing of the trays (as simply done as in the "No. 1 Sirocco") the attendant has nothing more to do than to move a handle up previous to inserting a tray, and down again, when he has inserted it, that is positively all!

By using this sirocco for "final firing" in the early morning, its emitted and still warm air can be conveyed in a canvas pipe to the withering floor above, for use in combination with the Blackman system of withering, which promises to have a great future before it. This would give a great start to the withering, before the first roll is ready for drying.

Having already taxed so much of your space, I will not venture upon going into any further details, but will conclude by hinting that planters coming home, may be sure of a hearty reception as old friends, should anything herein said tempt them to visit the Sirocco Works, where they will see much more than I have described to interest them.—I am, sir, &c.,
CHAS. H. LEPPER.

MR. MAY AND THE CEYLON ASSOCIATION TEA SCHEME.

31st Dec. 1888.

SIR,—Now that the May scheme has collapsed, owing to causes that I am totally ignorant of, it appears to be my duty to thank Mr. Rutherford, the Chairman, and members of the "Tea Fund Committee" and friends who supported the scheme for their generous aid; to state my profound regret that through me, they have been put to very great trouble, and to explain to them and the Planting community generally, that if any deception has been used, I am the most cruelly deceived of all.

Before introducing Mr. May to the "Planters' Association of Ceylon" I took, what appeared to me all necessary precautions to guard against a betrayal of its interest and, as previously stated investigated his business career and standing, as I believed, very thoroughly. I had interviews with Messrs. Brown Brothers & Co's. New York Manager, with the State Examiner of the Banks of the State of New York, with several merchants who had transacted business with Mr. May over a period covering several years, and also had read to me his standing in the books of the mercantile Agencies known throughout the United States and Canada as "Dun's" and "Bradstreet's" Agencies. Mr. May has been an extensive advertizer and, as far as I know, is so now, and in his Monthly Review he states that "Our

Bankers are Messrs. Brown Brothers & Co., New York, Messrs. Brown Shipley & Co., London and Liverpool, and their various branches and correspondents in all the principal cities of the world, and through them any financial transactions can be made. Messrs. Brown Brothers & Co's. connections are the strongest financial institutions in the World." At Mr. May's countryhouse there was every indication of refinement and luxury, and I was told that his wife and her family were the possessors and owners of extensive real estate and buildings in the town of Nyack on the Hudson River. From these different sources I gathered that Mr. May had means, energy and the business capacity to carry out any transaction that he might embark in to a successful issue, that he paid all accounts, bills, etc. promptly on presentation, and that his method of doing business was out of the ordinary rut and, therefore a little peculiar, but he was honest and straightforward in all his dealings.

The Chairman of the "Tea Fund Committee" has, I presume, later and more reliable data to go upon, judging from what fell from his lips at the meeting held at Nuwara Eliya on the 7th instant.

Unfortunately for me, Mr. May has not communicated his views and intentions to me in respect of the "Tea Fund Committee's" resolution which I forwarded to him on the 27th August, and, therefore, I am completely in the dark concerning them, and yet I cannot believe that he is going to remain silent or that he will treat me so undeservedly.

What concerns me most is that those who have so generously supported me may think I have tried to foist upon them a man of doubtful character and had taken no steps to ascertain his real one.

I need not take up your valuable space by stating, at length, what my feelings on this matter are, but I cannot forbear stating that I have acted throughout in good faith and in the firm belief that Mr. May was the right man. The failure of the scheme has been a cruel blow to me, but that is as nothing compared with the shame and disgrace of having been the instrument of deceiving a body of gentlemen that so kindly came to my aid and assistance. The fate of all pioneers has now overtaken me, and, added to the bitterness of failure and waste of time and money—is the uncomfortable, annoying thought that you, Mr. Editor, and many others may think my conduct in this matter has been one of premeditated and intended deceit.

Apologizing for troubling you, R. E. PINEO.

ARE WE TO HAVE A TEA TRUST?—It behoves the Ceylon tea planter and merchant to look ahead in view of the contingency referred to by the *Spectator* in an editorial as follows:—

The promoters of "Trusts" are going on with their work. It is stated on good authority that the Copper Syndicate hope to fix the price of copper for the next *twelve years*, and to fix it at the price now beginning to be felt so severely in State dockyards and ship-building concerns. A similar Syndicate, organised partly in America, is to drive up the price of lead, and make all plumbers' work even more of a terror to householders than it is. The Salt Trust has, it is stated, already doubled the price of ordinary salt at the pit's mouth, and nearly trebled that of block salt for export. The Chicago Wheat Ring is keeping wheat above a dollar a bushel, and the idea of a Coal Trust has not been definitely abandoned. We should not wonder if its promoters struck up an alliance with the workmen, who are much inclined to regulate output; and we expect every day to hear of a combination among the Tea-producers. Part of this movement, as we have explained elsewhere, is self-defensive; but part arises from the fact that a monopoly is the quickest road to fortune, and that with cheap money lying about in masses, monopolies are easy to control.

THE LANKA PLANTATIONS COMPANY, LIMITED.

DIRECTORS.—George Allen, Esq., R. P. Harding, Esq., Edward Pettit, Esq., Sir Herbert Bruce Sandford, James Thos. White, Esq. Agents in Colombo—Messrs. J. M. Robertson & Co. Secretary—Mr. William Bois.

Authorised Capital, £200,000 in 15,000 ordinary shares of £10 each and 5,000 preference shares of £10 each.

1. The Directors submit their Report for the 12 months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date.

2. The quantity of Coffee shipped home was 1,601 cwt., against an estimate of 2,640 cwt., and the amount realised therefrom was £5,883 6s 6d, the smallest return since the formation of the Company. The following statement shows the quantity of and the amount realised in each year since 1881:—

Coffee Crop from 1881 to 1888 and with Proceeds.

Year.	Aerial.		Fruit Hill.		Fruitless and small.		Ceylon and Ceylon.		Kappahoon.		Rappahoon.		Thotela-galla.		Yattawatte.		Total.		Proceeds.

Average Net Price 68 6 per Cwt.

3. The Cinchona Bark harvested has been about 133,598 lb., the greater part has been realised, and the whole is expected to produce £2,797 2s 8d. The depression in this market continues, and at present there seems but little prospect of improvement.

4. The quantity of Cocoa estimated was 700 cwt., but the crop only produced 471 cwt., realising £1,670 15s 4d. The Cocoa trees are now looking well and strong, and the shade trees growing rapidly the insect pest is disappearing, and there is every prospect of a good crop for the current year.

5. The Cardamoms also failed to produce the estimated quantity (4,000 lb.); there have been 2,350 lb. only received, which realised £161 5s 9d.

6. The Tea received from the Fordyce, Fruit Hill, and Ampitkande estates has amounted to 171,364 lb. (of which 68,000 lb. was the result of purchased leaf,) in addition to which 10,709 lb. were sold in Ceylon. The proceeds of the shipments of tea to London amount, to £7,664 9s 11d, and of the tea sold in Ceylon to £321 17s 5d, and it is expected that a larger return will be obtained this year without purchasing outside leaf. The erection of a Tea Factory on the Fruit Hill Estate was completed on 31st March last, and it is now in full work. A small Factory also has been erected on the Ampittikande Estate, and has been at work some time, but the growth of leaf has not yet been sufficient to keep it in full work, and some leaf has been purchased.

7. The land under cultivation for Tea is as follows:—

Estate.	Under 1 Year.				1 to 2 Years.				2 to 3 Years.				3 to 4 Years.				Total Acres.

a and 50 being planted this year. b and 50 being planted this year. c about 30 being planted this year. d and about 30 being planted this year. e and 50 or 60 being planted this year. f and 50 being planted this year. g about 30 being planted this year.

8. The dividends on the Preference Shares issued have been duly paid.

9. The Directors regret that the income for the year 1887-8 does not enable them to reduce the balance of the "Suspense Account" by writing off a percentage of the amount as in previous years.

10. The Coffee in cultivation at present promises a fair crop for 1888-89. The Director who on this occasion retires is Sir Herbert Sandford, and being eligible, offers himself for re-election. The Directors regret to have to report the death of their esteemed colleague Capt. Horace George Hayes, who was a large shareholder. The vacancy thus caused has been filled by the appointment of Mr. Edward Pettit, (of the firm of Messrs. E. & A. Deacon, Chius Merchants), and his election has now to be confirmed. It is hoped that his practical knowledge of Tea manufacture and the Tea markets will be of material assistance to the Company. Mr. John Smith (a shareholder) the Auditor, also retires and offers himself for re-election.

The Directors append a Statement compiled from the reports forwarded to them, by which the names, acreage, and state of cultivation of the Company's Estates, which has been compiled from the reports received from Colombo will be seen.

The Directors are informed that the great deficiency in the Coffee Crop was produced by the unusual and prolonged drought that prevailed in Ceylon during the early part of this year, which affected four of the estates, causing a failure of the fruit to give the usual sized coffee berry, although there was sufficient crop especially on the trees on the quantity estimated. When the crop was gathered it was frequently found that the loss was less than half the usual size, and

although when brought to market it sold fairly well it did not weigh above half the normal weight of Coffee, and to that cause is ascribed the unfortunate result of the year's working.

The Directors, acting under the advice of their agents and General Manager, and bearing in mind the high price now realised for Ceylon Coffee and the want of the capital which would be required if it were attempted to put any more of the Company's estates into Tea, have kept all their good coffee, which is reported to them as being in good condition and likely to bear excellent crops should the seasons (which continue to be abnormal in Ceylon as every where else) give them a fair chance. It is stated that whilst leaf disease is losing its virulence, bug, which has been the most serious enemy to coffee, is disappearing. It is hoped that the course pursued in this matter will shortly be attended with good results. Tea is a comparatively new industry and may develop disease of its own should it become the chief plant cultivated (as coffee has done), and it has been considered prudent to proceed cautiously in the matter.

The unsatisfactory results which have attended the cultivation of the estates for several years past have led the Board to the conclusion that a complete change in the management has become essential, and their views having been communicated to the Manager, he has tendered his resignation, which the Board have accepted, and they are now in correspondence with the agents in Colombo as to the arrangements which will be best calculated to ensure the improvements in revenue which have been so frequently promised, but have not been realised.—By Order, WILLIAM BOIS, Secretary.

No. 8, Old Jewry. Dec. 5th, 1888.

DRUG TRADE REPORT.

London, December 8, 1888.

ANNATTO.—No fewer than 81 baskets Brazilian Roll annatto were offered today, and holders would probably be glad of an opportunity to clear off the old lots, but only very low offers were obtainable, and 8½d per lb. was refused for a fairly good bright lot. Twenty-nine bales good Ceylon seed sold at 3½d per lb.

CINCHONA.—A rather small assortment of South American bark was offered today, and the inflated prices recently paid for certain varieties by foreign buyers were no longer obtainable. Guayaquil fine grey thin mossy quill brought 1s 11d medium quality 1s 7d to 1s 5d, broken stout and split 9d down to 5d per lb. For bright broken Lima only 2½d per lb could be obtained. For 18 serous so-called "cuzco" bark, appearing in long thin bright yellow flat pieces with brown outer layer, 1s 5d to 2s per lb is asked.

We have submitted a sample of the West African bark which was recently offered for sale to analysis, and found it to be of exceptionally rich quality; it contains 18 per cent of quinine and cinchonidine and 2½ per cent of cinchonins (pure alkaloids).

The Board of Trade Returns for November show the following results:—

	1886	1887	1888
Exports			
In November	cwt. 10,060	1,062	11,553
Jan. 1st to Nov. 30th	101,472	1,243,356	1,150,340
In November	value £ 33,310	19,092	34,795
Jan. 1st to Nov. 30th	£ 474,443	459,238	319,421

Exports.

In November	cwt. 10,060	8,344	11,553
Jan. 1st to Nov. 30th	101,472	1,243,356	1,150,340
In November	value £ 33,310	19,092	34,795
Jan. 1st to Nov. 30th	£ 474,443	459,238	319,421

The following figures show the exports of cinchona from Java during the last five seasons:—

Seasons from July 1 to June 30.	Private Plantations	Government Plantations	Total Amst.	Total Equi-valent in English lb
1883 to 1884	663,623	440,911	1,104,534	1,204,503
84	85	776,510	419,460	1,195,970
85	86	1,073,189	457,267	1,531,156
86	87	1,569,842	660,433	2,230,275
87	88	2,916,927	575,986	3,492,913

COCA LEAVES sold cheaply today. Ten bales of South American leaves, Huanoco character, good pale green and yellowish mived, sold at 1s. per lb., and six ditto, more or less damaged, at 11d. down to 6½d per lb. Two consignments of Java coca leaves, just imported, were also brought to auction. One of these consisted of 11 tin-lined boxes (25 lbs. each), the current season's crop of the "Soekamadgoe" plantation. These leaves were of excellent green colour and good flavour, and apparently of the Truxillo character, but cut small: No bids were made for them, and the lot was bought in at 3s per lb. nominally, 1s being solicited. The other parcel consisted of three packages of very common, small, and almost black leaves, such as have on one or two previous occasions been shipped from Java. For these not even 2d per lb. was obtainable.

COCAINE.—It appears that two of the manufacturers are determined to undersell one another, for after the reduction in the price of one of the German brands noticed last week, Messrs. Howards & Sons sent out a circular on Tuesday reducing their quotation to 16s 3d. per oz. for bulk, and we hear of even lower prices from second hand holders. Other makers are holding aloof from competition at present.

CROTON SEED remains steady, but there is no great improvement noticeable in this article. A few lots were offered at the auctions today, for two of which, showing very dull quality, 15s. was mentioned as the lowest price, while a much brighter lot sold at 18s per cwt.

QUININE is very sick. The German agents are not quoting at present, and the English and French prices remain unaltered, though the B. & S. agents report one sale at 1s 4d per oz. for December delivery, but a second-hand lot is reported to have been sold today at 1s 3½d per oz.

OILS (ESSENTIAL).—Sarsaparilla is still very firm in London, 6s 5d to 6s 6d being the quotation, and business is reported at the former figure. Cajaput offer at 4s 4d per bottle for good quality. Orangethal dull at 4d to 15-16ths d per oz. for native brands on the spot, and ever-growing shipments from Ceylon. Cassia has advanced to 3s 5d per lb. in London, and that price is said to be obtainable for small lots. Cablegrams from China this week quote 3s 1d per lb. "c.i.f." terms, steamer shipment, which is also dearer. All parcels arriving on the Hongkong market from the interior are readily bought up speculators; there is no stock left there, and the native dealers refuse to enter into contracts. Rose and Peppermint oils unchanged, with a prospect of a further advance in *La* (presumably an early date). Tea cases good West Indian oil of Limes are held at 2s 4d. per lb. Japanese Menthol is fully 6d to 9d. per lb. dearer, and at todays auctions 6 cases sold at 4s 7d to 5s per lb. for good white crystals, and 3s 10d to 4s. for common grey old to cheap crystals. Fisher's brand oil of Peppermint is held at 1s 11d. to 2s per lb. American oil of Peppermint is quoted very firm in New York. Dealers here ask 14s 6d. per lb. for H. G. H. African Geranium oil is said to be much dearer, and it is feared that the supply will be exhausted long before the next crop can be distilled. As regards Menthol one business in these varieties is extremely dull for the time of year. There is a good stock of both Peppermint

and Lavender in growers' hands, and the price of the latter shows signs of giving way, as we hear of some oil just changing hands at 35s., after having been kept over for a much higher figure. Peppermint is quoted at 25s 6d. to 27s. per lb., and Lavender at 35s to 40s. per lb., according to quality.

THE AMSTERDAM CINCHONA AUCTIONS.

Telegram from our Correspondent.

AMSTERDAM, December 13th.

At the bark auctions held here today 1,890 packages Java bark, being the entire quantity offered for sale, were disposed of at a slight reduction in price, the unit not averaging more than 10c per half-kilo, or 14-5thd per lb. Druggist's barks in quills, fine long whole to broken, and chips, sold at 9c to 79c per half-kilo (equal to 1½d to 1s2d per lb.); druggist's root bark at 19c to 25c (equal to 3½d to 4½d per lb.) For manufacturing barks of all varieties, good rich quill to broken ditto, and chips, the prices ranged from 11c to 78c (equal to 2d to 1s2d per lb.), and for root for manufacturing purposes from 35c to 69c (equal to 6½d to 1s 0½d per lb.) The principal buyers, in order of precedence, were the Amsterdam Quinine Works, the Auerbach factory, and Brunswick factory.—*Chemist and Druggist.*

NOTES ON PRODUCE AND FINANCE; TEA.

The *Financial News*, which has said a good word for tea shares on more than one occasion, recently returned to the subject in the following paragraph:—

Some of the tea companies will have good news for their shareholders at the end of the current season. The crop is turning out exceedingly well, and, as fair prices are being got for it, dividends should rise proportionately. The Jokai Company of Assam makes a particularly flourishing exhibit. All its nine gardens show an increase, and in some of them the crop will be 50 per cent above last year's. Up to the end of October nearly 2,000,000 lb. of tea had been made, an increase of 377,000 lb. over the same period of 1887. Through the recent amalgamation of several small companies with the Jokai, considerable economies in working have been effected. These, together with the large increase of production, cannot fail to have agreeable financial results for the shareholders. At the lowest estimate, the net profits of the year will exceed 20 per cent on the company's capital.

The Jokai Company is certainly a striking instance of the results which attend clear-headed and capable management.

The first annual dinner of the Ceylon Association in London, held at Willis's Rooms on Thursday week last, was an interesting gathering. Sir Roper Lethbridge made a long speech on the occasion, and congratulated those present on the magnificent success which had attended their tea-planting operations. Mr. J. L. Shand rightly came in for a large measure of praise for his exertions on behalf of the industry and it was generally recognised that the Ceylon Association in London bids fair to be a great success as an aid to the planting community in the island.

A new Indian tea company has just been registered, entitled the Eraligool Tea Company, Limited. The capital is £18,000, in £10 shares, and the object is to carry into effect an agreement, dated Nov. 30, 1888, and made between Robins Thomas Cooke of the one part, and Percy Mitchell of the other part, for the sale and purchase of the Eraligool tea estate situate in the district Sylhet, in the province of Assam, to carry on the business of cultivators and tea planters in all its branches. The first subscribers (one share each) are:—A. Bryans, The Cottage, Foot's Cray, Kent; J. H. Wilson, Oriental Club, Hanover Square, W.; S. A. Went, Newlands, Thames Ditton; W. Drew, Oriental Club, W.; P. R. Buchanan, Farm College, Epsom; V. Mitchell, 21, Queen's Road, N.; S. R. Anderson, 37, High Street, Eccleston Square, S. W. The first directors of the company will be Robins Thomas,

Tooke, Patrick R. Buchanan, and Samuel A. Went. The qualification of a director is the holding of at least £500 in the capital of the company, and his remuneration will be £2 2s for each attendance at a board meeting.

The following figures indicate the consumption of tea per head of the population of the United Kingdom during the last forty-eight years. In 1853 the consumption per head of tea first reached over 2 lb, and to 3 lb in 1864, thus taking eleven years to add the extra pound. From 1864, however, it only took eight years to add a further pound per head, as it will be seen that in 1872 the figures reached 4.01. Thirteen years elapsed before a further pound was again added, viz., in 1885, when the figure stood at 5.02. The year 1885, however, as regards tea was an unusual one, inasmuch as, during, several months of that year, duty payments were on an enormous scale, owing to a scare about a possible war with Russia; but it will be observed that since that year a relapse in consumption, carrying the figures to less than 5 lb per head, has taken place during the last two years of 1886 and 1887. This is somewhat remarkable when it is remembered that during the last sixteen years the bonded price of tea has fallen to such an extent as to be now just half what it was in 1872. The duty on tea was reduced in 1866 from 1s to 6d. The consumption of tea per head of the population in the year

The Committee for the Ceylon Tea Room at the Paris Exhibition consists of Sir W. Gregory, Mr. Whittall, Sir R. Lethbridge, Mr. A. G. Smither, Mr. J. L. Shand, and Mr. W. Martin Leake.—*H. and C. Mail.*

CEYLON PRODUCE IN LONDON.

Messrs. Gow, Wilson & Stanton—console Ceylon tea planters for low prices, by remarking that they are certain to cause increased consumption of their product! The best averages given are Charley Valley 1s 9½d (well done Mr. de Soysa's Sinhalese manager); Glenugie 1s 4d; Hope 1s 2½d; Ooduwelle 1s 1½d; Agar's land 1s 0½d, while several Dikoya and Bogawantalawa marks are well spoken of. In coffee, Coslanda (Haputale) tops the Ceylon market with 111s and 107.6; Meeriabedde in the same district rising up to 103s and 109s. These prices and the long lists of "nineties" and upwards are certainly enough to make every man in the island with a coffee bush, do his very utmost to preserve and strengthen it.—Ceylon cocoa keeps well up: pity there is not more of it.—Cardamoms pay well at present prices and with a limited production here the prospects are very good.—Cinchona Bark is weak, but there must be a good time coming, when—when—our exports go down to 250,000lb. a month!

Messrs. I. A. Rucker & Bencraft say on December 13th:—

The movements on the terminal markets are now very rapid up and down, a jump of 10s being accom

plished in a few days. Floods of "cables" with estimates are coming to hand, some one way, and the other way. We believe from the fact current crops won't be anything like as large as was at one time expected, and the growing crops will be on a very moderate scale. Under such circumstances, coffee will continue a high price article.

TEA PLANTING IN WESTERN DOOARS.

(From a Special Correspondent.)

JULPAIGURI, Bengal, September 21, 1888.—The Western Dooars is the youngest tea district in India, but it already made itself a good name. Most of the gardens in it are owned by companies with their headquarters in Calcutta, but these companies have not left the Western Dooars entirely alone. It is wonderful, indeed, that no more attention is paid to it by investors, for dividends of from 20 to 30 per cent are not considered at all out of the way for these properties. The district, which lies on the frontier of Bhutan, has been opened since 1875. During that period many thousands of acres of waste lands have been opened up and laid out in tea. In 1886 there were 54 limited liability companies and private concerns, having about 25,000 acres under tea. One great advantage which the district has is the "free labour" which flows to it annually from Chota Nagpore and the hills of Nepal. Assam and other districts have to pay from 70 to 100 rupees per head for their coolies. If the Assam gardens can pay dividends varying from 10 to 16 per cent, annually, though burdened with such heavy expenditure on labour, the gardens on the Dooars should be able to pay dividends rarely earned either at home or abroad. What is required to make a garden pay, "hand over fist" is a capable manager, who has local experience combined with push and energy. There is a great difference between working with "free labour" and with agreement labour, as in Assam, and a manager from that district, no matter how successful he may have been there, is of little use in the Dooars until he becomes acquainted with the new conditions. All gardens cannot be expected to pay alike, as some have very high-class plants, and others again, very low ones; but there is no reason why all should not pay reasonably. I shall give a special example of not only what can be done, but what has been done on a garden with a very medium class of plant and a comparatively poor soil. Like farmers in England, the planter has to contend against many evils in the shape of blight, and now and then has to suffer from a heavy drought. This year the Dooars has suffered from both, as well as a low market in Calcutta; yet managers are still sanguine of making fair profits.

One of our men I have used the expression "free labour," which does not mean that we get coolies to work without pay. The expression applies to coolies who work without an agreement to stay so many years on the garden, &c.; in fact, they are free to go and go as they please, and are in no way under Government supervision. There is still a good deal of land to be had for the cultivation of tea. The terms of competition are very light, and the yield of tea for the first year, 3 annas per acre in the second, 6 annas in the third, 9 annas in the fourth and 12 annas in the fifth. After 15 per cent of the total crop has been brought with good cultivation, and finally bears the plants, the farmer is entitled to a removal of the trees for a further period of 20 years, and to remove the timber periods in proportion, at a rate to be fixed by the Deputy-Commissioner on the order of the Government on application. The rent is not at all exorbitant, but paid for similar lands in the neighbourhood, under other arrangements. It would be a pity that the same conditions of competition should not be applied to other districts, as they are in the Western Dooars.

As an example of a garden which has been well managed, with a good result, I give the following details. The Good Hope Tea Company, Limited, of Calcutta, was opened in 1877, with a capital of a lakh of rupees, divided into

1,000 shares of R100 each. Tea culture on being new at that time, the planters had not so much experience of the soil or the class of plants best suited for the industry in Western Dooars. Consequently, the Good Hope garden possesses poorer soil and an inferior class of plant than other tea estates opened at since in the light of wider experience. Now, observe the history of Good Hope. Up till 1883, the garden was practically a failure, as it only once paid a dividend (8 per cent in 1881). At the commencement of 1884, when the present manager assumed charge,* the tide changed and has since flowed steadily along in the direction of prosperity. In that year the profit on the season's working was R7,567, or about 7½ per cent on the capital. A dividend of 4 per cent, only was declared, as R3,427 at debit of profit and loss account for the previous year had to be deducted. In 1885 the profit on the working was R46,460, or about 46½ per cent on the capital. The balance then at credit of profit and loss account, including R140 brought forward from last year, was R46,600, out of which a dividend of 40 per cent was declared, and R6,600 carried forward to 1886. The outturn of that year compared with the two previous ones, as follows:—1885, 1,646½ maunds; 1884, 1,301 maunds; 1883, 868½ maunds; and the average prices obtained were 1885, As. 12-6 per lb.; 1884, As. 9-9 per lb.; 1883, As. 9-6 per lb. These results were brought about by increased expenditure judiciously applied, for from R42,790 in 1883 the total outlay rose to R56,578 in 1885. The justification of this increase was a dividend of 40 per cent, as in the latter as compared with a debit balance in the former year. One feature about most Indian tea gardens is that while the outturn of the year generally exceeds the estimate, the expenditure rarely does. Thus in 1885 Good Hope produced 246½ maunds of tea more than was estimated, but the outlay was only R259 in excess. At this date the garden was 380 acres in extent.

In 1886 a dividend of 28 per cent. was declared, there having been a considerable drop in the Calcutta Tea Market; in fact, prices have been steadily declining, the Good Hope averages going from annas 12-6 per lb. in 1885 to annas 9-4 in 1886, and annas 8-10 in 1887. Still, 28 per cent., a balance carried over of R9,156, and an addition of 60 acres to the garden was a fair show for the year. Last year the profit on the season's working was R41,202, or 41-2 per cent, on the capital of the company. A dividend of 30 per cent, was made to the shareholders, and, says the report of the managing agents: "While providing for the expenditure to date on account of the new tea house and manager's bungalow, a further dividend of 8 per cent. can be declared and still leave R9,948-4 to carry forward to profit and loss account of the current season." The outturn of the garden for the past year compared with that of the two previous seasons was:—1887, 2,523 maunds; 1886, 2,214 maunds; 1885, 1,646 maunds. Last year other 60 acres were added to the garden, making the nice round figure of 500 acres; but, so far, the new acreage has not turned out very well. The company opened its new season with a credit balance of R-9,563, and it was estimated that this season would produce 2,800 maunds, at an expenditure of R33,404. The present season is nearly at an end, but it is impossible yet to say what the ultimate result will be.

The fortunate original shareholders have thus, in the last four years, received in dividends 110 per cent, so that—even counting the lean years previous to 1881—they have had a good return on their investment. The R100 shares are now quoted at Calcutta at R220. This garden is by no means an exceptional case. There are two young ones in the Dooars—namely, Hope and Matfield, that are expected, in a year or two, to outstrip any garden other than Good Hope. They have been pronounced by authorities from other districts as being the finest

* And when the planter had come into full bearing—
E. T. J.

sheets of tea they have seen. These results have been attained upon the Good Hope Garden by careful management; for, though the quality of the plants, the nature of the market, or the weather, affect the results, the success or failure of a tea estate in a great measure lies in the hands of owners and agents. They appoint the managers and assistants, and if third-rate men, with little experience, are appointed, there is very little likelihood of tea paying. The agents have also in their hands the supply of machinery, which should be good and in sufficient quantity. Now that our Indian teas have ousted China from the British market, there are several syndicates working up the Canadian, United States and Australian markets, and experts are at present studying the peculiarities of the different places, so that we can manufacture teas to suit them. When those markets are won over to Indian teas there is bound to be an enormous increase in the demand.—*Financial News.*

ALIMENTARY AQUATIC PLANTS.

By P. L. SIMMONDS, F.L.S.

In the last number of the "Bulletin of the Paris Society of Acclimatisation," 5th August, an article appears on this subject, which merits attention from the novelty of the information furnished, and while drawing one or two items therefrom, I may add some supplementary detail which will be interesting. It will come as a surprise to many that in Asia and in parts of North America thousands of people feed on the farinaceous seeds of certain water plants. I do not here allude to the enormous crops of cultivated rice in Asia, nor to the wild rice (*Zizania aquatica*), or *fuitans* of America, but to the various water-lilies, the seeds of which are such a large source of subsistence to many. Firstly we have the species of *Trapa*, known in India under the name of "Singhara." This plant is also cultivated on a large scale in the lakes and rivers of Southern China.

Fortune thus describes it:—"Being detained for some time at Shanghai, I resolved to penetrate, if it were possible, into the district of Kwey-chog-foo. In ascending the river in a south-westerly direction, I soon arrived, after passing Kea-Hing-Fo, a city of 220,000 inhabitants, at an immense pool, which I suppose communicates with the celebrated Lake Tai-ko. The water, not deep, was covered with *Trapa bicornis*, which the Chinese call 'Ling,' the bizarre fruit of which, resembling a bullock's head with two horns is highly esteemed in China. I noticed three very distinct varieties, one of which bore fruit of a fine red colour. Women and children in great numbers were paddling about in small boats of a circular form, like washing-tubs, collecting the seeds. Nothing could be more curious than these singular boats, large enough to contain the person and the product collected, and pushed about among the plants without injuring them. The sight of this immense number of individuals floating about in their little tubs in this swamp was to me most diverting."

Another voyager, M. Marchal de Lunéville, states: "The *Trapa bicornis* forms the food of the people when the rice crop is insufficient. The collection reminds me of the grape harvest in Europe. The 'Ling' is sown at the close of autumn, in those ponds where the water is shallow and clear, and in localities exposed to the south. The Chinese affirm that this culture absorbs the putrid emanations which rise to the surface of the stagnant waters. If the harvest is abundant the seeds are given to poultry, which fatten readily on them, and their flesh acquires an exquisite flavour. This water-chestnut, as it is termed, is considered refreshing and agreeable food in summer. In its green state it is sold in the markets of Pekin as nuts are in Europe. Dried and reduced to flour it makes a good gruel, and it may be mixed with flour for bread. Roasted or preserved in sugar or honey it is a pleasant food. It is also excellent food for geese, ducks and other birds of the poultry yard."

The species which is cultivated in Kashmir, accord-

ing to Roxburgh and Sir J. D. Hooker, is believed to be *Trapa bispinosa*, although usually stated to be *T. natans* and *T. bicornis*. It is met with from Central and Southern Asia (where it is called *Singhara*), to Ceylon and Japan, and also reaches in the south of Africa to Zembezi. To this species probably belongs *T. Cochinchinensis*, Lour.; and *T. incisa*, Seib. *T. natans* is said to have furnished a large part of their food to the ancient Thracians, in the same manner as *T. bispinosa* does at the present day to the inhabitants of Kashmir, and *T. bicornis* to the Chinese. It is mentioned by Dr. Boyle that the former yielded as much as £12,000 a year of revenue to the Government of Runjet Singh, the tax being levied upon from 9,600 to 124,000 ass loads from the great Lake of Ooller.

In Kashmir, after a severe famine, the Governor of the district in which is situated the Woos Lake, introduced the culture of the *Trapa*. This lake, which measures at least 5,000 acres, is so filled with this plant that navigation is impossible. The fruit is collected by entire boatloads, and the governor derives a large revenue from it. Many of these boats filled with the seeds arrive daily at Srinagar.

The seeds of the *Trapa bispinosa* and *T. natans* contain a great quantity of fecula, and are eaten by the natives. In Gujerat they form an important article of food. During the Hooly festival a red dye is made from the fruit, mixed with a yellow dye from the flowers of the *Butea frondosa*. Colonel Sleeman has given the following interesting account of this plant in his "Travels in the South-Western Provinces":—"Here, as in most other parts of India, the tanks get spoiled by the water-chestnut (*Singhara*), which is everywhere as regularly planted and cultivated in fields under a large surface of water as wheat or barley is on the dry plains. It is cultivated by a class of men called Dheemurs, who are everywhere fishermen and palankin bearers, and they keep boats for the planting, weeding, and gathering of the *Singhara*. The holdings or tenements of each cultivator are marked out carefully on the surface of the water by long bamboos stuck up in it, and they pay so much the acre for the portion they till. The long straw of the plants reach up to the surface of the water, upon which float their green leaves; and their pure white flowers expand beautifully among them in the latter part of the afternoon. The nut grows under the water after the flowers decay, and is of a triangular shape, and covered with a tough brown integument adhering strongly to the kernel, which is white, esculent, and of a fine cartilaginous texture. The people are very fond of these nuts, and they are carried often on bullocks' backs two or three hundred miles to market. They ripen in the latter end of the rains in September, and are eatable till the end of November. The rent paid for an ordinary tank by the cultivator is about 100 rupees (£10) a year. I have known 200 rupees to be paid for a very large one, and even 300, or £30 a year. But the mud increases so rapidly from the cultivation, that it soon destroys all reservoirs in which it is permitted; and where it is thought desirable to keep up the tank for the sake of the water it should be carefully prohibited."

In Kashmir, miles of the lake and marshes are covered with it, and the fruit forms the staple food for some months in the year to a large number of people. It abounds in starch, resembles a chestnut in flavour, and is eaten either raw or cooked. Flour is made of it, which is eaten by Hindus on fast days, also made into sweetmeats.

A variety of *T. natans*, to which the name of *T. verbanensis* has been given, is cultivated in the Lakes of Majena and Varesa in Italy, especially in the Bay of Angera, Lake Majena, where the bottom is visible. With the seeds chaplets of beads are made, and sold at Benares, and considered very sacred.

Capt. J. P. Pogson, of Simla, advocated some years since, in the "Journal of Applied Science," the more extended culture and utilisation of this plant. "With the example of Kashmir before us, it seems

very singular that the vaulted tanks, large lakes, and inland fresh-water sea of the Madras Presidency, as well as the immense 'jheels' of the North-Western Provinces and Oudh, are not, as a rule, turned to most profitable account by being placed under Singhara cultivation. The dried nuts will, I believe, keep for many years, an arrowroot, or rather Singhara starch, will always sell in England, either as food or for manufacturing purposes, all old Singhara stock could be so converted and sold.

Like the grain of wheat, the kernel of the Singhara nut is capable of sustaining life for an indefinite period, and is palatable, whether seasoned with salt and pepper, or made into porridge with sugar, ghoor, or jaggery. If the kernels are broken into small bits, they may then be ground into meal in a hand-mill, and the produce kneaded up into dough, and made into small 'chuppaties,' or cakes. If the kernels be soaked overnight in cold water, next morning a simple boiling converts them into food—steaming would do as well, perhaps better; but I have, as yet, only tried the soaked kernels in the boiled state. I have years ago eaten 'bulwa' made of Singhara meal, and it was more palatable than that made from fine wheat flour.

The Madras Presidency possesses some magnificent ancient waterworks. The Vitium tank, with its area of 35 square miles and its embankment of 12 miles; Cauverypank tank, with its embankment of 4 miles, rivetted along its entire length with stone; the Chembrambankum tank, looking like a picturesque inland sea, are of unknown antiquity. The first of these artificial lakes equals 22,400 acres of surface, and the third being compared to an inland sea, may be ten times that size. It is an official authenticated fact that in Kashmir, 30,000 human beings are, for five months out of the year, fed and sustained on the Singhara nut, and if the picturesque inland sea under notice is at all deserving the name, its bed and water surface might be most profitably utilised by being put under Singhara cultivation. The tank of 35 square miles might become a first-class nursery for supplying seed nuts to Madras.

The productiveness of the water-nuts, per acre, is at present unknown; but supposing the yield to be four quarters (480 lb. each) of nuts kernels per acre, then the 22,400 acres would give 43,800,000 pounds of food, and at 60 lb. per adult per month, the above quantity would suffice to feed 716,800 human beings for one month, and 143,360 adults for five months. The cost of this large and perennial supply of food would be a mere trifle. There are 4,000 square yards in one acre, and allowing one seed nut to each yard, the price of the nuts and the railway freight may be easily calculated. The first year's harvest would more than cover all cost and thereafter in perpetuity a harvest would result which would only have to bear the cost of watch, ward, and collection. The entire crop being State property, a very considerable revenue would be derived from the sale of the nuts, even if kernels were sold at half the price of rice or other grain.

In good season, the agricultural population would freely use this cheap and nourishing food, and sell and export rice crops, &c., and in bad seasons of famine the growing crop of water-nuts would be a stand by. In fact, their presence would go far to prevent the artificial production of local famine.

The nuts once sown re-sow themselves, and in this way the square yard might soon be growing five water plants or more. The inland sea, when covered with these nuts, would be a source of wealth to the State, and the people would be greatly benefited. As the usual extension of the cultivation, spreading up and inland, is a very simple affair, the Madras Government would, in a few years, find themselves to be the proprietors of one of the richest agricultural plantations in the world.

The nuts once sown re-sow themselves, and in this way the square yard might soon be growing five water plants or more. The inland sea, when covered with these nuts, would be a source of wealth to the State, and the people would be greatly benefited. As the usual extension of the cultivation, spreading up and inland, is a very simple affair, the Madras Government would, in a few years, find themselves to be the proprietors of one of the richest agricultural plantations in the world.

deeper water, any sort of raft, float, or canoe will have to be used, and the nuts picked off. In this country (India) several pickings take place during the season, and the last batch of nuts, i.e., those that are of a large size and the kernel hard, are boiled and so eaten. Others are shelled and dired and made into meal, while others again are buried whole, to be used next season for seed. For example, the pool or depression which has borne a crop of nuts may dry up during the hot weather; when the rains commence the locality will become a pool *de novo* and the stock of seed-nuts are then dug up and sown twelve inches apart in the shallow water, putting each nut about two inches deep in the submerged soil, and this process is repeated daily as the waters rise. In due course the nuts will germinate, and yield that year's harvest. Of course if the water did not dry up the old roots would remain alive, and in season send up a fresh crop of stems, which would in due course bear fruit. Hence, if required to become a perennial crop, the nuts must be sown in the beds of shallow freshwater pools which never dry up."

The Pythagorean bean, the *Nelumbo nuciferum*, Gaertnær; *Nelumbo speciosum*, Willdenow; and another species (*N. luteum*), have seeds of a particularly pleasant taste. The capsular fruit contains from twenty to forty of these seeds. The seed-vessel is of a peculiarly beautiful form, the top becoming detached when ripe, discloses a chamber with five partitions. The seeds were much used as food in ancient Egypt, but seem to be neglected now. These retain their vitality for several years. The tuberous roots of both species resemble the sweet potato (*Batatas edulis*), and are starchy. The root-stocks when boiled are farinaceous and agreeable, and employed as food by the Osaga and other Western Indians.

The seed-vessel, or receptacle of the fruit of the lotus (*N. speciosum*) is large, in the shape of an inverted cone, and has the nuts placed loose in apertures, or cells, on the surface; it has not inaptly been compared to the rose of a watering pot. The whole in process of time separates from the stalk, and laden with ripe oval nuts floats down the water. The nuts vegetating, it becomes a cornucopia of young sprouting plants, which at length break loose from their confinement, and take root in the mud. The lotus flower is highly venerated by the Hindus, and is given as a valuable offering to the gods. The seeds in India are eaten raw when green, and roasted or boiled when ripe and hard. The root, which is two or three feet long, is eaten, boiled, as a vegetable.

The Klamath Indians of North-West America live chiefly on the "tookow," or seeds of the yellow water lily (*Nuphar lutea*), which is the staple of their winter food. The capsules are broken, and the seeds separated from their husks.—*Journal of the Society of Arts.*

[No. 8.

THE COCONUT PALM:
ALONG THE LINE OF THE BENTOTA
RAILWAY EXTENSION.

WE revert to the interesting subject of the seaside railway extension to correct an error into which we fell, in stating the daily task of each man engaged in uprooting and felling coconut palms to be one tree. The number is really too. Even this number may seem small to persons who have not watched the process and noticed the remarkable manner in which the coconut palms are buttressed by means of exceptional bulblike growths in and above the ground and held in the soil against monsoon storms which sometimes bend the elastic stems to the very horizon by a most remarkable series of roots, capable of resisting as strong a strain as the best cordage which can be made of the coir which covers the nuts. It was a curious effect to see many of the masses which formed the lower portions of prostrate palms, dotted over with fresh brownish red marks on the spots where the spreading roots had been torn out of the woody portion by the force of the fall. A careful observer once told us that he had followed these roots down to a perpendicular depth of thirteen feet, and it is quite certain that horizontally they extend to at least twice that distance. The extent to which the ground is permeated by the large roots which are tough enough to resist in some cases several strokes of a mamoty, added to the tangled masses of uncountable feeding rootlets which intervene, makes earthwork cutting on many parts of this side line a somewhat difficult work. We need scarcely add that the size of the root masses of the trees, and the number of rootlets, and so the hold of the trees in the ground, differ according to the nature and quality of the

soil, the latter varying from almost pure sea sand to rich mould as at Kalutara, with coralline and laterite formations towards Beruwala and Bentota. In all its varieties, however, from sandy to swampy, the sea-shore belt between Colombo and Galle, and especially south of Kalutara seems, with the favourable climate (plenty of wet, but not too much moisture), to produce coconut palms of exceptional luxuriance and especially of unusual height. We recollect the astonishment expressed by a friend whose eye had been accustomed only to the palms of the Jaffna Peninsula, after he had travelled along the Galle road, at the loftiness of the trees generally and especially the altitude attained by the coconut palms. It remained for Mr. Cantrell, however, to settle by actual measurement the fact that the coconut palm, under special conditions (close planting being perhaps one of these?), attains an altitude of considerably over 100 feet. It seems probable that amongst the many thousands of trees to be felled along the line of railway, some may be measured up to 120 feet, the maximum, we should think, to which the coconut palm can anywhere attain? We should be interested in learning whether anywhere on the earth's surface taller specimens of this palm exist than those growing south of Kalutara. We mean, of course, heights ascertained by actual measurement, for we attach but slight importance to guess estimates, knowing how grossly exaggerated are the notions formed by casual observers of the height (Mr. Caine's figure was 150 feet) and the bearing capacity of these wonderful trees. A gentleman who accompanied us in our recent trip, and who was comparatively new to Ceylon, was surprised to learn that it was not common for a coconut palm to yield 100 nuts per annum, and that a crop of 200 nuts from a tree was so rare and exceptional an event as to be quite phenomenal. Our companion, like a great many others, was greatly disappointed to learn, that, according to the usual mode in which

native groves or topes are grown, the trees so close together as absolutely to exclude, in many cases, light and fresh air, even 30 nuts per annum was a high average. We have seen coconut palms, under exceptionally favourable circumstances of shelter, room, light, air, soil, and fertilizing matter, bearing 100 nuts and even 200 nuts per annum; and one of the best-informed writers in our columns on the subject of coconut culture has expressed the opinion that with proper culture, including the free application of nitrogenous and phosphatic manures, whole plantations might be made to yield several times the usual average crop, without affecting, except favourably, the longevity of the trees. The companion referred to asked us as to the life of a coconut tree, and we had to reply that we could give no definite reliable opinion. Sixty years was often vaguely stated, but, although we have seen apparently old trees ceasing to bear, we have seen others spring into new activity with improvement of the soil in which they were growing, while there are many groves of coconut trees in and around Colombo which we have been in the habit of seeing at intervals for half a century in which we have observed no appreciable change. They were mature when we first saw them, and they still show no signs of decay. It would be interesting to learn, on reliable authority, what the real life of the average coconut palm is, and what the comparative longevity of palms grown for fruit bearing and those devoted to "toddy-drawing" (abstraction of the saccharine juice of the flower-spathe) for distillation into the spirit known as arrack. At first sight it might seem that the constant abstraction of the juice would be the more exhausting process, but we are bound to state that in the dense groves of the special arrack region near Kalutara, although fruits were few and far between, the trees themselves looked fresh and flourishing. Some of the ground in which the very finest and tallest trees were growing was semi-swampy, so that with the effect of the close planting added, the atmosphere was permanently damp. The result in the case of many of the trees, bent towards the horizon as is the tendency of this species of palm, was that abortive roots were sent out and root processes assumed on the lower face of the trees, for lengths several feet along the trees above the ground. Sometimes the adoption of root processes can be seen on trees growing as straight as coconut palms can, at a considerable height up the stem. It looks as if imperfectly growing trees instinctively threw out roots to obtain the benefit of the damp atmosphere and then started growing *de novo*. In some cases where the root masses were not sufficiently loosened, they retained their hold of the soil, and the stem above the bulb-like formation broke away. In such cases it was curious to notice the close resemblance of the fibrous stem-wood to the coir fibres of the nuts. Fibrous as the wood is and always soft at the heart, the vascular bundles of fibres in the outer portions attain great density with age, the weight of a specimen in Mendis's list being 70 lb. per cubit foot. Besides being useful as rafters, reapers, and spouts in house construction, choice specimens are used in cabinet work, nice chairs and tables being made of it. It is known in Europe as "porcupine wood." The present is a good opportunity to obtain superior specimens of the wood, care being taken in the choice, for all old wood is not hard. In any use made of the coconut trees, the soft inside portions should be cleared away; otherwise in their decay they form the habitat of the maggot of the great black coconut beetle. Reverting to the question of

age, we need scarcely tell our local readers that the curious scars left on the cylindrical stems, as set after set of grand pinnate leaves or rather branches fall away, give no more decisive proof of the number of years the trees have existed, than "rings" do in the timber of ordinary trees grown in the tropics. Annular marks here, instead of indicating annual growths, are as frequent as the changes of wet and dry seasons. Hence the extravagant estimates of age of trees such as 7,000 years, wildly attributed to *Adansonia digitata*, by writers adopting the principle applicable to in Europe. We may notice here that interesting and pleasant and convenient as the journey along the seaside by railway is, only a carriage or coach ride along the old road can give an idea of the wealth and beauty of the vegetation and foliage: palms and jak and bread-fruit trees, country almonds, mangoes, cashew trees, mangosteens, lovi-lovi, bilimbis, and when the swamps approach the road, pandanus and varieties of mangrove intermingling with ferns and flowering shrubs.

The railway will command beautiful views of river, lake, sea, sward, fort, town and hills in the distance at Kalutara, but a drive will be necessary to obtain a sight of the beautiful banyan which spans the road, its horizontal branches and buttressing or snake-like stems being richly adorned with ferns and other epiphytal growths. The railway will in some cases run between perfect walls of coconut palms, so densely set together, that one of the greatest difficulties in surveying the line was that of obtaining anything like lengthened "sights" through the thousands of closely-planted columnar growths. Such stretches of the railway will give travellers a vivid idea of the prevalence of this special cultivation along the south-western shores of Ceylon. For several years after the railway is opened, palms on the sides of the line will have to be cleared away, as they obey the tendency to lean towards the open space where there is available light and air. With so many stations too, we may look for the same process which has taken place on the Colombo-Kalutara section, the erection of nice dwellings, with gardens and garden cultivation of a variety of trees and plants, to relieve the monotony of the ubiquitous coconut palms. We have already alluded to the effects of close planting as injurious to healthy growth in the case of such fruit trees as coconuts, the bread-fruit (which is forced into tallness, while its true habit is umbrageousness), jaks, mangoes, and so forth. Grateful too as the shade was to our party, while inspecting the course of the line, we could not help feeling that "more light" would help in the growth of a more lively and robust race of people than those who crowd the densely-shaded groves along the seashore. We were not merely amazed at the number of human abodes concealed amidst groves which almost completely shut out the sun, but struck with the contrasts presented between the really handsome houses of renters, headmen, and well-to-do traders, and the often semi-ruinous huts of the fishermen, husbandmen and poorer classes generally. We felt that houses and people as well as palms were too closely crowded, and we were pleased to believe in the opportunities for swarming out which the railway will afford. The inland pasture grounds can be improved, and by means of the lime and laterite formations which abound, especially as Beruwala is approached and onwards to Bentota, the swamps can be redeemed. The gneiss metamorphosed into cabook exists in very varied forms, from soft rich clay, passing rapidly into excellent soil with exposure to the atmosphere, to hard ironstone masses or nodules

which will form excellent ballast for the railway. [By the way, this reminds us that a long disused cabook quarry (has, in view of its being taken over by the railway, been awakened into full activity!) Mixed with laterite and lime (broken chips of coral unburnt, even, will correct the acidity and bring out the fertility of the rotted vegetation) the swamp lands will become eventually as fertile and as capable of supporting life,—vegetable, animal, and human,—as is now the seashore fringe, and so the inland solitudes will be made lively and vocal by measures of redemption which the railway will render possible. And why should not the backwaters become scenes of the breeding of superior species of fish and of oysters such as those for which Bentota is famous, as it is for its beautiful and airy position, overlooking the sea and the river, the latter passing from brackish water into fresh.

One of the regrets of a most enjoyable day and trip when concluded, was that time did not permit of a visit to the lighthouse, which we saw rising in columnar grace from the beautiful palm-covered islet off Beruwala on which under the direction of Mr. Pilkington and his assistants, it has so rapidly risen. At Beruwala may be said to commence that system of low hills, running down from the mountain ranges to the seashore and breaking up into undulations, and rocks, and capes, and bays, and islets, which render the scenery of the coast at and on each side of Galle, so strikingly romantic,—so “beautiful exceedingly.” We trust that many years will not elapse ere all this splendid seashore scenery, (with cool sea breezes) to the southern point of land in Ceylon which looks from beneath a tropic sun to antarctic fields of eternal ice, may be available to travellers and tourists by railway.—One other regret we may be permitted to mention before we conclude. It is that one who for twenty-two years has done such good service to the colony as Mr. Cantrell, should have been so inadequately rewarded. He has now a grand chance of showing what scientific skill and local experience can accomplish. We have no doubt the result will be good work at a minimum cost, and we trust the ruling authorities of the colony will respond to what we know is the wish of the colonists, that good and faithful service should be rightly appreciated and duly acknowledged.

COFFEE AND TEA.

I have quite recently heard of some marvellously good coffee crops from the Uva side of the country in localities too high and dry to be within reach of that fell destroyer—bug. The Badulla property of Mr. C. B. Smith, I am assured, yielded in one year not less than 9 cwt. per acre of good marketable coffee and at the rate mentioned to me quite recently, at which Ceylon Plantation has been dealt in by private contract for the Continent, viz. 102s. This crop should prove most encouraging. Then again, I hear marvellous things of the returns from Mr. Dutt's Badulla estate, as well as from Nayabedde and Wiharagalla in the Haputale district. The Dambatenne estate also continues to do well for its owner. By the bye, I believe the original proprietor of this property, Mr. J. Wright, for many years a timber contractor in the Lunenburg district, is living in perfect health at some village not very far from Ipswich.

A special meeting of the Ceylon Tea Plantations Company, Limited, will be held on the 20th instant to confirm the arrangements come to by the Directors for the enlargement of the Company's investments by the amalgamation of the following properties with those already belonging to them, viz., Wallaha, Scrubs, Elleries, Aiton and Uperet, the properties of Messrs. Fisher, Wallahan and D. Reid respectively. The figures at which these plantations have been taken over have not been mentioned to me, but I am assured they are such as are considered highly satisfactory by both

buyers and sellers. The Company will now have in their possession tea properties at both high and medium altitudes, so that in the event of any severe drought in the low-country affecting their crops there, they will have the shortfall in pluckings made up to them by the more favorable yield at such a time of their higher estates and this is a contingency well worth bearing in mind. The charge of all these properties will involve a good deal more responsibility as well as hard work, and Mr. Rutherford, therefore, does well to determine on taking a holiday in this country during next summer.

The long pending case of *Laing v. Somerville & Co.*, regarding “Cash on delivery,” and which your readers will, no doubt, remember as connected with a claim of Messrs. Baker and Hall against Mrs. Robertson, was finally heard and decided last week, when the Judicial Committee of the Privy Council (Lord Hobhouse, Sir Richard Couch, and Sir Stephen W. Flanagan), were moved by Mr. J. H. Helpman, barrister-at-law (instructed by Messrs. Hickin and Fox of London), on behalf of Mr. Laing, to dismiss, with costs, Messrs. Somerville & Co.'s proposed appeal to their lordships on the ground of want of prosecution. The learned counsel having briefly stated the leading facts of the case, their lordships at once assented to the application. So the appeal is disallowed, and the appellants will have to pay the amount at issue with interest at 9 per cent and costs.—*London Cor.*, local “Times.”

THE SUMATRA TOBACCO PLANTATION COMPANY (LIMITED).

(To the Editor of the *London and China Express*.)

Sir,—In your issue, dated 10th inst., in a paragraph in the Money Article, you mention that it is your belief that the estates recently acquired by this company were formerly under the superintendence of Mr. Tolson. If not troubling you too much, will you kindly correct this, as the estates have been held by Mr. A. P. Bernard only?—I am, &c.,

CHAS. BISCHOFF, Secretary *pro tem*.

40, Old Broad Street, Dec. 14.

ROOFING PAPER.

Sandakan, 23rd Nov. 1888.

To the Editor, *British North Borneo Herald*.

Sir,—Through your aid I would call the attention of Planters and of the public generally, to the great utility of Willesden Roofing paper which, so far as I can see is quite unknown here.—I was surprised to see vast quantities of ataps shipped from port to port on my way down here not only for roofing but for walls. Willesden paper is very portable, cheap, indestructible almost, and perfectly waterproof and would last four or five times as long as ataps. I have used some of it as water spouting and have had it in use for some 8 years and it is now as water tight as it was when I put it up. I cannot imagine anything more suitable for tobacco sheds or for the style of houses you build here. In Ceylon Messrs. Cave & Co., are the Agents from whom all particulars as to price, freight &c., &c., can easily be obtained.—I am, Sir, Yours faithfully,

McM. CHALLINOR.

NOTES ON PRODUCE AND FINANCE.

The Trust project, to which we recently referred, is in active preparation. It is proposed to include securities other than tea shares in the Trust, and no doubt the field is both wide and profitable if organised on a sound basis.

The scheme for pushing the sale of Indian tea in America makes slow progress, although a great deal of individual effort has been exercised, with the object of bringing it to a successful issue. It would be refreshing to hear that active operations had commenced and that the tea drinkers of the leading cities of the United States were able to procure and taste Indian tea with a view to a regular demand for the American market.—*U. S. M.*

NORTH BORNEO NEWS.

(From the *British North Borneo Herald*, Dec. 1st.)

We understand Messrs. E. E. Abrahamson & Co. have been granted conditionally two lots of 5,000 acres of land in the vicinity of the Padas River, West Coast District.

The Court of Directors have purchased 3 bales of the Ranow Tobacco Crop to compete for the £50 prize offered by the London Chamber of Commerce, in December next.

THE CONSUMPTION OF WOOD FOR RAILWAY SLEEPERS.—The *Moniteur Industriel* states that the six principal railway companies of France use more than 10,000 sleepers per day, or 3,650,000 per annum. As a tree of the usual dimensions will give only ten sleepers, the railways in question require 1,000 trees per day for sleepers alone. In the United States the consumption is much greater, amounting to about 15,000,000 sleepers a year, which is equivalent to the destruction of about 170,000 acres of forest. The annual consumption of sleepers by the railways of the world is estimated at 40,000,000 and this is probably less than the actual number. From these figures the rapid progress of disafforestation will be understood, and that it is certain that the natural growth cannot keep pace with it. Hence we have had during the last quarter of a century frequent inundations and changes in atmospheric conditions. These and other considerations tend to the ultimate employment of metal for sleepers in place of wood.

The East Borneo Company is not letting grass grow under its feet, jungle has been cleared and sheds erected as if by magic and 100 coolies recently obtained on comparatively small advances from the West Coast near Gaya. These men are we hear giving every satisfaction and we think other planters might follow Mr. Abrahamson's example with advantage thereby avoiding the heavy advances paid to Chinese and Javanese, and all risk of loss from desertions.

COFFEE PLANTING is in active progress on the Trading and Planting Co.'s Segalind estate. The samples of tobacco produced there are of very good quality, and judging from the fine quality of the fruit of some trees found in the jungle, cocoa is likely to do well.

Mr. M. Challinor arrived at Sandakan in the S. S. "Mercury" on the 22nd ultimo to take up his appointment as Assistant Surveyor in the Land Department. We note from the *Ceylon Observer* that he has been a resident in Ceylon for the last sixteen years, and the Editor expresses a hope that good health, success and fortune may follow his footsteps here, in which we heartily join.

We have been favoured with a copy of Ferguson's Ceylon Handbook and Directory for 1887-8, which fully sustains the reputation secured for its predecessors.

His Excellency Sir Arthur Gordon, Governor of Ceylon in writing to the compiler Mr. J. Ferguson states "I am fully aware of its interest and value and of the profit to be gained from a judicious examination of the same. I doubt very much whether any Colony, except perhaps Victoria, where they take immense pains with their annual returns and statistics, has anything approaching it in completeness and accuracy."

Mr. von Donop informs us that through the courtesy of the Fiji Government, he hopes shortly to have Fiji Cotton plants for distribution.

Mr. F. R. Boulton, M. I. M. E., Manager of the British Borneo Trading Company has obtained letters Patent for a useful contrivance in connection with Circular Saw Benches, for cutting shingles shooks for tea boxes, packing cases, cigar boxes, venetians, etc., etc.

We hope to hear that shortly the Company are supplying the Ceylon Planters with boxes for packing their tea in and local residents with shingles for their bungalows.

KUDAT NOTES.

As old residents and as pioneers of the tobacco enterprise we heartily welcome the Count and Countess de Geloos d'Elisloo back amongst our small community here.

The object of the intending emigrants is, we have

reason to believe, to plant pepper, on the rich lands round Kudat harbour.

Many of the estates are still cutting tobacco, a fact which surprises visitors accustomed to the earlier seasons in Deli.

Mrs. Dominic Daly returned to Kudat in the *Memnon* on the 12th instant, much benefited by her sojourn on the coast.

CLEANING STEAM-ENGINE BOILERS.

There are now so many steam engines employed on tea estates in Ceylon, that the following extract from "Chemical Engineering" in the *Chemical Trade Journal* will be interesting and useful:—

Before I leave the subject of steam raising, it may be as well to insist on the necessity for cleanliness inside the boiler. The loss of heat taking place in some works through scale in boilers is simply incredible. I have only just finished the analysis of a boiler scale sent me for examination which measured no less than 3½ inches in thickness, and which doubtless could have been prevented by proper means.

The subject is simple enough: water contains carbonate and sulphate of lime, and very often salts of magnesia. The sulphate is held in simple solution, but the carbonate owes its solubility to an excess of carbonic acid present in the water. Upon heating this acid gas is expelled, and down falls the carbonate of lime. If this be done quickly the carbonate falls as a sludge to the bottom of the boiler, while if it is deposited slowly a scale is produced and is bound together by the sulphate of lime which falls simultaneously. There are many nostrums in the market for preventing and removing scale, but only two substances need be employed. The cheaper is caustic soda, pumped in with the feed water; the other, tribasic phosphate of soda, which is especially useful where the degree of "permanent hardness" is excessive. Many manufacturers have told me that they have tried caustic soda and not found it effective, but on careful inquiry, I have always found that far too little was employed. If we suppose a boiler consuming 40 tons of fuel per week with an evaporation of 7.5 lb. of water (of 15° "total hardness," of which 7° are "permanent") per lb. of fuel, we can readily find how much caustic soda is required. The quantity of water per week for one boiler would be 300 tons or 67,200 gallons, which at 8° of "temporary hardness" per gallon, would mean at least 77 lb. of 60 per cent. caustic soda per week to simply absorb the carbonic acid holding the carbonate of lime in solution, thus enabling it to drop quickly.

The caustic soda thus introduced becomes converted into carbonate, which acts further upon the sulphate of lime, converting it into carbonate and becoming itself transformed into sulphate of soda. It will thus be seen that something more than the mere addition of anti-incrustating agents is necessary. The sulphate of soda formed by the decomposition of the carbonate remains in solution, and where soda crystals have been used without frequent blowing down, I have found as much as 500 grains per gallon of soluble matter in the boiler water. Then again, there is the carbonate of lime sludge which must be systematically removed, as in the case already cited, the wet sludge will amount to at least 2 cwt. per week.

Some have objected to the employment of caustic soda owing to the action it has upon brass fittings; but this has arisen when a large quantity of caustic soda has been put into a boiler newly cleaned, and allowed to last say for three weeks or a month. Of course during the early stages of the new running the water is excessively alkaline, and the tendency to froth and prime and even to attack brasswork is very great. The only sensible way is to mix it with the feed water in due proportion whereby the caustic becomes carbonated at once; but it is a question whether the steam boiler should be made the receptacle for all the dirt and filth from the water; I think not, for I am strongly of opinion that it would pay much better to effect the purification of the feed water before it entered the boiler.

CEYLON TEA IN AMERICA.

10th Dec. 1888.

The Editor, the *New York Times*.

Dear Sir,—Referring to the admirable letter on the subject of tea, which appeared in your Sunday's issue, we would take exception to one remark which is not strictly true, and is apt to mislead. We refer to the statement which reads as follows:—"Oolong, which is really the purest and best, is the favorite." [The whole paragraph reads:—

"Tea may be divided into three general classes—green, black, and scented.—and these are again subdivided according to the size of the leaf after its manipulation, the division being effected by sifting. Of green tea there is gunpowder, which is in small round pellets, and imperial, which is larger. When the roll is long it is called hyson and when long and narrow it is young hyson. Of black teas there are Moning and Kaisong, Oongou, Souchong, Oolong, Orange Pekoe, Canton, Foo-Choo, and Caper plain and scented. There are also different kinds of India tea. This tea has a more penetrating flavor and fuller body, qualities that are more highly appreciated in England than in America. A good deal is imported into this country from India, but it is chiefly used for mixing with other teas, the people in this country preferring a more delicately flavoured tea, and Oolong, which is really the purest and best, is the favorite. When picked it is almost already sun-dried, so that it is finished in the pans at once and is almost exactly the same as when taken from the bush, except that the moisture is evaporated."]

That Oolong is the favorite tea among Americans of today, is true, and that it is an exceptionally pleasant tea to the palate, is equally true. But is it the purest and the best? Having been for many years a planter in Ceylon, the writer can speak with some authority on the subject of tea manufacturers, and while Oologns only be freer from impurities than most China and Japan teas: they are scarcely be called the purest when compared with Ceylon teas which to the writer's certain knowledge have never been and probably never will be subjected to any manner of adulteration whatsoever as far being the best. In what respect is an Oolong superior to a Ceylon tea? The latter contains more theine than the former. It is twice as economical in that it is a inner bodied tea and only half the quantity is required that is used of Oolong to get a tea of equal strength and flavour. It is more wholesome, as the astringent qualities are not so marked as they are in Oologns.

We have no wish to write at length as critics of the able article before us, but would fain correct what we know to be a misstatement, no doubt unwittingly made by the writer who has favoured the public with the interesting sketch referred to.

We refer you to a pamphlet we circulated a year ago on the subject of tea cultivation in Ceylon, from which you may glean some interesting information regarding the rise and progress of the tea enterprise in that island and the mode of preparation, of which differs materially from that of China tea, inasmuch as it is prepared by machinery without the introduction of any manner of scenting or colouring matter.

From our pamphlet you will learn that from 25,000 lb. of tea exported in 1878, the exports in 1886 reached 10,000,000 lb., and we can now report that the estimate for the current season of 32,000,000 lb. is likely to be realized. How is this for progress?

As regards quality, Ceylon tea, by the latter part of the year, under our supervision first in the London market. As you may see that if the general public had they are generally considered to be the best grades of tea in the world, since we are the only one. We can answer the question *Juste ou pas?*

Before we conclude that what we have submitted to the public is a mere advertisement for the benefit of the Planters' Association of Ceylon, let us state that at the earliest possible date, the editors of the *New York Times*, of at least *New York* will be available, be presented with a copy of pure Ceylon tea, and thus afforded an opportunity of testing the

quality for themselves. We heartily supported the scheme, and hope that in about 3 months from date we will have the pleasure of sending you a sample caddy with the compliments of the planters of Ceylon.—We are, dear sir, yours truly,

J. M. MURRAY & Co.

USE AND VALUE OF MANGANESE.—With reference to the existence of manganese in the formations through which the Haputale railway will run, we make an extract from a notice in the *Indian Engineer* of minerals in the Hyderabad (Southern India) territory:—"Then, there are Manganese ores, valuable always, but of peculiar value just now, when steel is fast supplanting iron in English ship-building yards. For it is a well enough known fact that, owing to magnetic attraction, the compasses on steel-built vessels are sometimes betrayed into untrustworthiness, and mislead those who look to them for guidance—only too often with disastrous results. Now, lately in England a process has been invented, by means of which Manganese, in the proportion of about 27 per cent, is mixed with steel; and it is contended that this admixture frees the steel from magnetic influences. Manganese used to be worth, on an average £2 5 0 per ton in England; it will probably be worth much more now."

HOW SILK CULTURE AND OTHER INDUSTRIES—can best be promoted in Ceylon may be learned (more particularly by the Director of Public Instruction) from the Chairman (Mr. James Samuelson) at the last distribution of prizes to the Liverpool Science and Art classes. Among other things he said:—

As far back as 1869 he found an institution at Ellhofeld, in Rhenish Prussia, where young girls were taught, amongst other things, silk weaving, and some beautiful work done by the pupils was shown to him. Such institutions were numerous in Germany and elsewhere in connection with textile and other manufactures. Even in countries which we were in the habit of looking upon as half-civilised, technical instruction in the best sense was pushed forward with great vigour. In 1882 he visited in the neighbourhood of Bucharest a most comprehensive School of Agriculture and Forestry, in which the youths of the country were taught to cultivate and utilise every part of the soil that Roumania was capable of growing, and last year, in the neighbourhood of Sofia in Bulgaria he had paid a visit to an institution, for giving instruction in the working of wood and metals, which he ventured to say, though on a limited scale, surpassed any institution of the kind elsewhere. Out of England, in our own Empire, great attention was being paid to technical instruction. In Ireland the agricultural school at Glasnevin was a model institution. We ought to have 50 such in England, instead of constantly clamouring for State intervention to protect our farming industries—(hear, hear)—and the country which was attracting almost as much notice as Ireland, namely, India, was making a vigorous move in the same direction. (Hear, hear.) As regarded education in India, he (the chairman) hoped to be able to speak from personal experience on his return from that country to which he intended going very shortly, and where he should send the wider-inquiring into that amongst other subjects of public interest. In conclusion, he spoke out strongly of the necessity for combining technical with elementary education in this country, as it existed at present. Such a combination would make technical education popular with the working classes, it might be met by the more new being made by the grades given in the country. They talked about "teaching the man to be a mechanic and the mechanic to be a man," but they had not got the first part of the plan, which was absolutely necessary to enable us to compete with foreign nations.

A "RED BANANA."

Very commonly cultivated as a shade and fruit plant, and the supply of which is said to be almost inexhaustible, has been brought forward as a possible source of commercial fibre. A sample of fibre prepared from this red banana was recently sent to Kew, and the opinion of Messrs. Ide and Christie obtained upon it. Their report, dated October 29, 1886, is as follows:—"We think highly of this fibre, for which we consider there might be a considerable demand, provided it could be produced of a better colour. We are inclined to think its dull hue is probably the result of inexperience in its treatment either by allowing it to steep too long in rather foul water or from the leaves being too old and discoloured before treatment. The attention of preparers should be directed to the production of a fibre of the bright natural colour of the enclosed specimen of Manila hemp, and were quantities of the new fibre produced of this appearance, we think they would command 24*l.* or 25*l.* per ton to-day in the London market. Colour is of great consequence when fibres are used for the production of 'white hemp' ropes. Of course, in the manufacture of tarred rope, colour is of no moment, but the white 'hemp' manila, Sisal and New Zealand are seldom tarred. It is quite possible, Mr. Morris says, that in spite of many years of experimental trial the fibres of the banana and plantain many not assume great commercial importance. In that case attention might be turned in another direction and they might be partly prepared on the spot and utilised for paper-making. But to compete successfully with esparto and wood-pulp the fibre or "half stuff" of banana and plantain he says should be delivered in Europe at a cost not exceeding 4*l.* to 6*l.* per ton depending on condition. For paper making it might be sufficient to cut the stems into short pieces and then divide them longitudinally into numerous narrow strips. These after being passed between rollers to get rid of the water and mucilage might be dried in the sun and afterwards put up in compressed bales for shipment. The whole subject, however, as Mr. Morris rightly observes, resolves itself into a question of cost, and it can only be practically solved in countries like Demerara, Trinidad and Jamaica, where several thousand acres are occupied by banana plantations, and where sufficient material lies close at hand to maintain a moderately large industry.—*Colonies and India.*

PIASABA FIBRE.

From the Proceedings of the Madras Agri-Horticultural Society we quote as follows:—

Read the following letter from the Ordnance Officer in charge, Arsenal, Fort William, No. 2496, dated 6th June 1888:—"I have the honor to request you will kindly inform me, if your Society can supply this Arsenal, with any Piasaba (a Palm growth) which is required for Government manufactures. When in Madras about 2 years ago, I obtained some by sending coolies up the palms for it. A sample taken from a bush is forwarded herewith for inspection. I regret that I have no full length spines. In the event of none being obtainable from the Society, I would feel much obliged by your kindly informing me, to whom I should apply, as also the Botanical name for the palm, on which Piasaba is found." Read also the following letter from the Honorary Secretary, dated 16th July 1888, No. 1010, in reply:—"In reply to your letter No. 2496 of the 6th instant, I have the honor to inform you, that we have no palm here known by the name of "Piasaba." We have carefully gone over the list of fibre-yielding palms, in Watt's Economic Products of India, Vol. IV, the names of which are, *Arca catechu*, *Arenga saccharifera*, *Borassus flabelliformis*, *Calamus rotang*, *Caryota urens*, *Chamareps litcheiana*, *Cocos nucifera*, *Corypha umbraculifera*, *Licuala peltata*, *Phanix sylvestris*, *Phoenix farinifera*, and *Phanix talulosa*, under none of which can we find "Piasaba." The only one of the above Palms that produces fibre in quality to

agree very nearly with the sample you sent, is *Caryota urens*, which though not common about Madras, is probably obtainable in small quantities in some of the Hill Forests. A sample of the fibre of *Caryota urens* is herewith sent for your inspection. If it be suitable for your requirements, and you can give us some idea of the quantity wanted, and the cost to which we may go in sending out men to collect it and forwarding it to you, we shall be happy to endeavour to comply with your wishes."

Read the following letter from the Ordnance Officer, Arsenal, dated Fort William, 24th July 1888, in reply:—"I have the honour to thank you for yours of the 6th instant. The fibre, specimen received, is too weak for arsenal purposes, for which something stiff but not brittle is necessary. I find that Webster calls Piasaba, Piassava fibrous product of the palm tree *Attalea funifera*, imported from Brazil. In the days when the Oape route was the only one for India, vessels used piassaba swabs to clean their decks, and they then went under the head of ciar or coir. The old sailors remember them well, but they have been quite out of use for some time." Recorded. Resolved that further enquiries and experiments be made on the above subject.

A FOREIGN VIEW OF THE QUININE MARKET.

The cost of making quinine is discussed by the *British and Colonial Druggist*, and the following conclusions arrived at:—

The present state of the market for sulphate of quinine is not without interest. That sulphate should be sold at 1*s* 3*d* seems almost ridiculous, when it is remembered that at that figure it is impossible to manufacture it without loss. We have it stated on the best authority that 1*s* 4*d* is the lowest price at which the article can be made at a profit, whilst the value of bark remains as it is now. Despite the prognostications which are made in some quarters and circulated in others—prognostications which are all detrimental to the prospects of bark—the value is steadily maintained, and all attempts to depreciate it fail. We are always being told of large shipments which are coming forward from Ceylon, but although these are never lost sight of, we seldom hear anything with regard to the stocks existing there, which must necessarily be getting lower every time a shipment is made. The policy of some manufacturers in selling quinine for forward delivery at low price, is one which they may some day have cause to regret. We ourselves cannot see the object of it. Of course, manufacturers may be able to see further into the future than other people, and may possibly be able to foresee such a fall in the price of bark as shall enable them to do more than recoup themselves for the risk they run, but up to the present the power of seeing into the future appears to be confined to themselves, as at each succeeding sale of bark, both here and at Amsterdam, the prices realized are, contrary to what we should be led to expect, fully equal to, if not better, than those obtained at the previous one. Admitting the fact that sulphate cannot be manufactured at less than 1*s*. 4*d*. per ounce without leaving a loss to the maker, the sellers at 1*s*. 3*d*. must be losing a considerable amount of money over the transactions. How long they will continue to do so is a question, as we have already said depending either upon the value of bark or upon their willingness to keep on selling at a loss. Doubtless every effort will be made to depress the market for cinchona, and we have already seen a circular issued which was calculated to have that effect (but the only result of which was to momentarily depress quinine), and unless these efforts are successful, it seems almost certain that the contracts recently made at 1*s* 3*d*. must in the end result in loss to the seller. Already the steady tone exhibited lately in regard to bark is beginning to make itself felt upon market for quinine, the latter having become much

firmer during the last few days; and it is true that the German manufacturers were unable to fully supply their wants at the recent sales at Amsterdam, the improvement in sulphate may develop itself to an even greater extent before the lapse of many weeks.
—*Oil, Paint and Drug Reporter.*

LARD AND COCONUT OIL.

By ALFRED H. ALLEN.

I am induced to make this communication, without waiting for a meeting of the Society of Public Analysts, on account of the very active interest now attaching to lard adulteration. In the last edition of my "Commercial Organic Analysis" (vol. ii., page 142), the assertion is made that "coconut oil has been employed for adulterating lard," but I am unable to trace the authority on which I made the statement. Personally, I never found, nor, indeed, looked for, coconut oil in lard until quite recently, as I have regarded the peculiar odor or flavor of coconut oil as an inseparable barrier to its unacknowledged use. This difficulty is now surmounted. A few weeks since I received a sample of lard for examination under the Sale of Food and Drugs Act, which, on Analysis, gave the following results:

Water.....	0.86 per cent
Indicated plummet gravity at 99° C.....	8666
Iodine absorption.....	37.4 per cent
Nitrate of silver test.....	negative

These results were so extraordinary that I at once suspected the presence of coconut oil, and this suspicion was fully confirmed by the following additional data:—

On original fat:	
KHO required for saponification.....	21.15 p. c.
=Saponification equivalent.....	265.2
Volume of N-10 alkali required by the distillate from 2.5 grms. by the Reichert-Wollny process	3.3 c.c.

On separated fatty acids:	
Mean combining weight.....	253.01
Volume of N-10 alkali required by distillate from 5 grms.....	3.5 c.c.
Plummet gravity at 99°.....	98400
Iodine absorption.....	42.5 p. c.

The volatile acids obtained by the Reichert-Wollny process contained a notable proportion of solid acids of sparing solubility in water, and had the characteristic odor of the distillate from coconut oil. I certified the sample to contain 33 per cent of the adulterant.

It is evident that the very characters which render it difficult to detect and determine coconut oil in butter suffice to make its detection and determination in lard, even in presence of cottonseed oil and tallow, a certain and fairly simple matter. This will be evident from an inspection of the following figures:

	Lard.	Coconut Oil.
Plummet gravity at 99°		
Original fat.....	860 to 861	861 to 862
.....	56 to 61	60
Iodine absorption.....		
Saponification equivalent.....	286 to 292	209 to 228
Volume of N-10 alkali required by distillate from 5 grms.....	9.5	7.0
Separated fatty acids:		
Plummet gravity at 99°		
.....	848 to 849	844
Iodine absorption.....	61 to 64	15-01
Mean combining weight	278	201

The more accurate determination of the amount of adulterant from the saponification equivalent, as this criterion is practically unaffected by the presence of cottonseed oil or tallow. Failing this, the average saponification equivalent of lard is 284, and that of coconut oil at 210, there is a difference of 70, and hence every 0.70 of fall in the equivalent below 289 indicates the probable presence of 1 per

cent of the adulterant. Comparatively small proportions of coconut oil in lard can be detected and safely certified.

In conclusion, I may add that some time since, I received very pressing inquiries from America as to where coconut stearin could be obtained, but was compelled to reply that it was not now in the market. Some months ago I met with a butter, which was undoubtedly adulterated with coconut oil.—*Oil, Paint and Drug Reporter.*

CANES AND STICKS USED IN THE MANUFACTURE OF WALKING STICKS, UMBRELLA HANDLES, &c.

By J. R. JACKSON, A. L. S.

Coffee.—These sticks are the produce of the ordinary or Arabian coffee-tree (*Coffea Arabica*), and are brought here from the West Indies. They are very hard and heavy, with a light-coloured bark, and have but little to recommend them.

Ebony.—Several kinds of ebony are known in the trade as Ceylon, Macassar, and flowered ebony. The two former are the produce of *Diospyros ebenum*, and the latter of a totally different plant, namely, *Brya ebenus*. The first is a native of Ceylon and India, and furnishes the best true ebony, while the second is a small tree, native of the West Indies, and is sometimes known as green ebony and cocus-wood, so much used for making flutes. The ebonies furnish very choice sticks, which are cut from the solid wood.

Eucalyptus.—This, as its name implies, is the produce of *Eucalyptus Globulus*, better known, perhaps, as the blue gum. It is a native of Australia, but has been introduced into many other parts of the world. The supply for the stick trade comes from Algeria.

Burze, sometimes also known as *Whin* or *Gorse* (*Ulex europæus*).—The stems of this common British plant are, as is well known, very irregular in their growth. When they are straightened and properly dressed, however, they make extremely pretty walking and umbrella sticks, and are in great demand.

Myall Wood (*Acacia homatophylla*).—A leguminous tree of Australia, the violet-scented wood of which is well known and has been much used of late in the manufacture of pipes. The sticks are not polished so as to preserve the scent.

Nana Canes.—This name has been given to the hollow reed-like stems of *Arundo donax*, the rhizomes of which form excellent handles for umbrellas and sunshades. They are imported from Algeria.

Oak (*Quercus Robur*).—The saplings and branches of this well-known British tree are much used for walking sticks, and are always in demand. Under the name of Brazilian oak, a stick that has met with a very large demand has been known in the market for some few years. It is corrugated longitudinally, and knotted throughout, the knots being especially thick near the knob. Though this stick is a great favourite, its botanical origin at present is obscure. It is imported from Bahia, and is sometimes known as *Quercus Mylæ*.

Orange sticks.—The orange sticks, which are imported chiefly from Algeria, are probably the produce of other allied species besides that of the common orange (*Citrus aurantium*). The bark of the tree, when dressed and polished, has a bright, shining colour, with white streaks, and makes extremely pretty sticks, for which there is a constant demand.

Orange Wood.—This is a distinct product from the foregoing, and is not furnished by any species of *Citrus*, but by the common *Citrus aurantium*. The bark has somewhat of the orange marking, but its colour is nearly black, as its trade name indicates. It is imported from Algeria.

Black and Red sticks.—These sticks are cut from the solid wood of the *Palmyra* palm of India (*Phoenix dactyloides*). Two varieties are known, black and red, the one with intense black lines, the other with red. The wood is imported from India. The red must be coconut wood?—Ed. T. A.]

Penang Lawyer (Licuala acutifida).—This is a palm, the saplings of which, with the roots attached, are imported in considerable quantities from Penang.

Pimento (Pimenta Officinalis).—A tree common in Jamaica, where it is largely cultivated for the sake of its fruits, which are the allspice of commerce. For the stick and umbrella trade large quantities of the young saplings are imported from the West Indies. The sticks are valued specially for umbrella handles, in consequence of their rigidity and non-liability to warp.

Pomegranate (Punica Granatum).—These sticks come mostly from Algeria, where they are specially cultivated.

Rajah Cane.—This favourite stick has been known in commerce for some twenty years or more. It is imported from Borneo, and for a long time after its introduction its botanical origin remained a mystery. It has, however, since been referred to the genus of palms *Eugeissonia*, and probably to the species *minor*. The commercial name rajah is said to be derived from the fact of the duties paid for its export being claimed by the Rajah of Borneo.

Rattan.—Under this name a variety of sticks, apparently the produce of different species of *Calamus*, are known. Thus we have root rattans, white hard-barked rattans, monster rattans, miniature rattans, and so on. They are all of a similar character, with the scars of the fallen leaves strongly marked in transverse rings. They are the produce of Eastern countries.

From the foregoing notes it will be seen how extensive are the resources of the walking and umbrella stick trade at the present time, and how the forests and jungles of the world are laid under contribution to supply the material.

The following estimate of the annual imports of some of the principal canes from the East here referred to will further illustrate its commercial importance:—

Description.	Country.	Approximate quantity.
Bamboos.....	China and Japan.....	5,000,000
Partridge canes.....	China.....	2,500,000
Tonquin canes.....	China.....	20,000,000
Malacca.....	Siak.....	250,000
Whangee.....	Japan.....	600,000
Rattan.....	Singapore.....	100,000
Other Eastern canes	China, &c.	500,000

28,950,000

Besides these, the number of various kinds of rattan canes imported from Singapore and other Eastern countries amount in weight to about 1,500 tons, while of sticks other than canes we have of olive, myrtle, orange, and various kinds from Algeria, as many as 2,000,000; and of hazel, dogwood, cherry, &c., from Austria, Hungary, and France, about 3,000,000. The total value of the sticks in the raw state imported from all countries may be estimated at about £300,000.

—*Journal of the Society of Arts.*

ST. HELENA.—This isle in mid ocean, once so important as a calling place for East Indian and war ships and famous as the prison of Napoleon, has fallen on evil days. This is obvious from a letter in the *St. Helena Guardian* of Oct. 18th, which we quote as follows:—

St. Helena stands in unique position and depends entirely on the calling of ships and Imperial expenditure for almost every farthing spent within it. Supposing tomorrow the Government were unfortunately to withdraw the Troops, and the few ships and men-of-war which now call were to keep off from our harbour for any time or continuously, what difference would there be between St. Helena and Tristan da Cunha except that here we should have an exceeding far larger starving population dependent entirely on such supplies as the surrounding sea and scanty acreage capable of cultivation and the feeding of cattle and sheep would afford. Fortunately the retail prices of the absolute necessities of life such as rice, flour, sugar, &c., were never cheaper than at this time, but the poor man properly exclaims, what is the benefit of this to one who has no means whatever of taking advantage of their cheapness! It is only tantalizing him to call his attention to it.

TOBACCO.—The large company for growing tobacco in Borneo, to which we referred some time since is, we hear, likely to be brought out very shortly. The area of land that has been acquired is as much as 40,000 acres. Meanwhile, we may state that the shares of the London Borneo Tobacco Company (Limited), the final call on which becomes due on the 1st prox., are quoted £3 to £4 premium. Offers at £3 premium have been more than once refused. —*L. & C. Express.*

INDIA-RUBBER AND OPIUM AT MOZAMBIQUE.—The following note on the produce of the rubber at Mozambique occurs in a recently issued Consular report. The writer says:—"Rubber is obtained mostly from the lower districts nearer the sea. There are two qualities, differing in their method of preparation. The better is that drawn from cuts made in the stems of vines, and made up into balls without further preparation. The inferior quality is got by boiling the rubber-bearing stems and roots; it is white, contains much moisture, and commands a lower price than the other. The supply of rubber continues to be maintained, but cannot be expected to last very long, as in some districts the vines have all been destroyed by the reckless way of gathering employed by the natives. It has more than once been proposed to try systematic planting of rubber trees, but nothing has yet been done. There is no doubt that the supply could be increased, as well as made more certain, were cultivation gone into systematically, and the gathering of the rubber not left to the mercy of natives. The total export in 1885 was valued at £1450. Referring to the cultivation of opium, it is said that at Mopea it has been put on an entirely new footing. In some other places—namely, at Ohamo, on the Shiré, and Mafufu, on the Ziwa-Ziwa—opium culture has also been under the auspices of the Mozambique Produce Company, Limited, of London.—*Gardeners' Chronicle.*

TEA PROSPECTS.—Our special telegram from Calcutta reports that the Indian Tea Exports while showing a steady advance, have not yet attained the estimated excess over those for the previous season. Counting both the Indian and Ceylon exports to the Australasian Colonies, the total is still quite an insignificant proportion of the whole quantity consumed. There is however good reason to look forward to a considerable increase in the export of Ceylon teas to Melbourne during 1889. From all sides we hear of our produce being greatly appreciated in Victoria, Tasmania and New Zealand. Mr. Wm. Mackenzie ought to be able to give his brother planters valuable information on this point. Here is what "Old Colonist" says under date 24th November, where he was wroth under the idea that Ceylon had made up her mind to boycott Australia in the matter of tea!! He wrote:—

I do not, of course, believe in "No freight", there is more in it than this. In olden times when Colombo agents got 18 per cent of the estate expenditure, besides a rebate on freight the proprietors wot not of, want of freight was never heard of then! Now the pendulum is too far the other way; the planter starves the poor agent; hence freight difficulty; make it worth his while, and no more will be heard of no freight. One thing I am certain of is that the market now for pekoe souchong at 1s in bond is practically unlimited in Australia as far as Ceylon is concerned. No need to give away gratis; nothing indeed more likely to bring the tea into disrepute. On the other hand, Mr. J.F. Wingate writes:—"I fear there is not much to be done in Pure Ceylon Tea in New Zealand. Blended rubbish has taken too strong a hold of the general taste to be easily supplemented." But on this a Colombo merchant well remarks:—"Then if this is so everyone should try and get any N. Z. acquaintances of theirs to turn over a new leaf—this can only be done by sending them an occasional present of really good Ceylon tea telling them how to make it."

HAVE WE THE TRUE MASHEER IN
CEYLON, OR ONLY A MISERABLE
PRETENDER ?

It would seem as if the controversy as to the existence of the true mahseer in Ceylon would pass into the interminable. Some people are inclined to charge the Ceylon representative of the giant freshwater fish of India with having more than a set of teeth in his throat. That he is not "the real Simon Pure" Mr. Jeffries of Gangaruwa is certain; for, so far from being a pure fish, Mr. Jeffries has told Mr. Haly of the Museum, that "psychologically (*sic!*) the Ceylon fish is dull and heavy, giving little or no sport" (thus failing, of course, to meet the main purpose of its existence), and worse still for those who care for good fish more than they care for sport, it is as deficient gastronomically as it is psychologically, its flesh is dangerous, being at times very poisonous! If this is the normal character of the mahseer, and not an aberrant condition, dependent on the food eaten by the fish (poisonous blossoms and fruits), Mr. Le Mesurier is surely acting as a very questionable benefactor to Ceylon in the earnest attempts he is making to propagate this stupid, insipid, dangerous and at times very poisonous fish! Mr. Le Mesurier it was who first sent specimens from Bintenna, which Mr. Haly says he at once identified as *Barbus tor* (the true mahseer), as he recorded in his report for 1887. Notwithstanding this, an Indian visitor was very sceptical; naturally enough if Mr. Jeffries has given our fish a true character as neither good to angle for nor pleasant to eat. So, according to correspondence in the local "Times," Mr. H. MacLeod supplied the sceptical Indian with specimens from the Mahaweliganga, which Mr. W. L. Sclater of the Calcutta Museum identified as *Barbus longispinis*, so closely allied to *Barbus tor* that "for all practical purposes the mahseer may be said to exist in Ceylon." But what comfort does this afford to anglers or gourmards while Mr. Jeffries cries:—"Poisonous fish!" Mr. Haly accepts Mr. Jeffries' condemnatory judgment with respect, but our Museum Director vehemently scoffs at synonym-mongers and subdividers of species, as altogether fishy without the merit of freshness. Listen:—

"Synonymy in Zoology too often represents either the carelessness or ambition of authors, the want of proper comparison with previously identified specimens, or the desire of seeing one's name attached to a new species, but this is not the case with *Barbus tor*; to a great extent the names under which this species has been described really do express observed difference. If you follow Dr. Day you will consider

that the Mahseer is a fish of wide range, living under very different conditions, and consequently subject to great variations. If on the other hand you are not disposed to accept authority, you may divide the species into six or even eight, or you may consider them merely sub-species, or you may make two or three species with sub-species or varieties under them. The openings for heterodox opinions are almost unlimited.

"In *Barbus tor* the lips are lobed; in some individuals they are very fleshy indeed. When this character tends to become obsolete, as it does in fish living in gravelly streams, it is very difficult to distinguish them from the common Kelani *Barbus hexastichus*."

In view of all this, it is of importance to know what species, sub-species, or variety, Mr. Le Mesurier is taking out of the Kotmaleganga and distributing: *Barbus tor*, *B. longispinis*, or—*B. hexastichus*? But more important even than niceties of classification are the questions of character. Is it only in that portion of the Mahaweliganga which runs through the valley of Dumbara and the lower country generally, from Bintenna down to the splitting asunder of the great river near Trincomalee, that the mahseer is dull in disposition and "fusionless" in flesh? If so, are the unfavourable characteristics owing to soil, or climate, each affecting the water, or, more probably to the prevalence of trees on the banks which drop blossoms and fruits of a narcotic nature and which blossoms and fruits the fishes feed on, and so become inert in disposition and unwholesome in tissue? Are the upper affluents of the Mahaweliganga, which run through Nuwara Eliya, Dimbula, Kotmale, Maskeliya, Dikoya, and Ambagamuwa, free from such influences, and is the mahseer in those regions lively on the rod and pleasant in the pot? Mr. Le Mesurier and other disciples of Isaak Walton ought to be able to tell us something to our advantage in reply to such questions, or the wider a berth we give to mahseer the better. It is surely curious that freshwater fish in Ceylon should generally be so questionable; partaking of it so frequently followed with unpleasant effects. The only marked exception is the *lala* (mahseer is *lala*), which seems to be good always and at all seasons.

Once again we are induced to suggest that the Madras Government be asked to allow the great piscatorial authority, the Hon. Mr. Thomas, to extend his inquiry regarding the freshwater fish and fisheries of Southern India, so as to embrace the neighbouring island of Ceylon. Why should fishes which are wholesome in Southern India be poisonous in Ceylon?

"COCONUTS" TO BE THE CRY, NOT TEA.

Mr. Beddington left by the P. & O. S. S. "Chusan" this afternoon for Calcutta. He will "tour" northern India, and then proceed to England. He, however, intends to invest in Ceylon, and so we shall probably see him back in the course of twelve months or so. His investments in different parts of the world have been very successful. In reply to our inquiry, as to whether he was "going in" for tea, he replied:—"No, I don't believe in it. I think the planters here are too sanguine, and I fully believe that the average will go down to 8½ before two years are over. How then will the planters be able to make tea pay? I have formed this opinion on the best authority—on the authority of a great friend of mine who is a leading broker in Mincing Lane, and who visited India and Ceylon last year. He is a man who knows all about the business, and is right in his conclusions in 99 cases out of 100, and it is his opinion that Ceylon tea will not beat either China or the Indian districts."

We suggested the name of a gentleman we thought likely to be identical with Mr. Beddington's friend, but he would mention no names. Mr. Beddington purposes investing in coconuts, but will not reside here. In the meantime he will appoint someone to "spy out the land" for him.

We may also mention that Mr. H. A. Todd, who came out the other day, is—like his late father before him, the wellknown Jaffna planter,—going in for coconuts, and this morning left Colombo for the Horrekelly estates, where he will "serve his 'prenticeship," before going to the North.

CEYLON AFFAIRS (TEA) IN LONDON.

London, 14th December 1888.

A. Philip, Esq., Secretary, Planters' Association, Kandy, Ceylon.

Dear Sir,—I now have the pleasure to forward copies of correspondence in regard to the sampling, &c., at wharves and docks in London. I will send you shortly copies of letters from nearly all the chief wharfingers on the subject. Having made direct inquiry as to the samples of coffee sent by Mr. Humphrey to be kept in the dock warehouses, I find that he is correct as to the practice at St. Katherine's Dock, but not as to that at the London docks where no such samples are kept. There are two docks belong to the same Company.

While discussing the question of short weights with Mr. Andrew Buchanan, he pointed out to me that in the case of tea it would often happen that a considerable loss might arise to the owner owing to the practice of taking as the gross weights of each package the pounds only and neglecting the odd ounces, while in the tare any odd ounces are taken as a full pound, thus on a package weighing gross 80 lb. 14 oz. the gross selling weight would be 80 lb. only, and if the empty package weighed 22 lb. 2 oz., it would be taken as weighing 23 lb. and the tea which actually weighs 58 lb. 12 oz. would be sold as 57 lb. only, showing a loss of weight of 1 lb. 12 oz.

As a remedy for this Mr. Buchanan proposes that care should be taken on the estates to make the tares always 2 oz. and no more under an exact number of lb., say 22 lb. 14 oz. And the gross weights should be carefully brought up to about 4 oz. over some number of lb., say 80 lb. 4 oz. Then on each package the loss from this source will be reduced to 6 oz. on each package.

The above refers of course to teas that are bulked in London.

Mr. Buchanan says that if anyone will try the above plan and will send the tea to his warehouses (the City Bonded tea warehouses), he will be glad to arrange

for any representative of the owner to attend, while the various operations are being gone through by the Customs.

PARIS EXHIBITION.—As it is necessary that some steps should now be taken for completing the arrangements for the tea-room in the coming Exhibition, I have taken on myself on behalf of your Committee to ask several gentlemen to act with me as a Committee in dealing with Mr. Shand; Sir Wm. Gregory, Sir Roper Lethbridge, and Mr. Whittall have agreed to act, and I am now asking Mr. Smither also. These gentlemen with Mr. Shand and myself will, I hope, be a Committee that will meet with the approval of your Association.—I am, &c.,

(Signed) WM. MARTIN LEAKE.

NEW CRANE WHARF CASE.

Ceylon Association in London, 65 Fenchurch Street, London, 5th November 1888.

Ernest Humphrey, Esq.

Dear Sir,—At a meeting of the Executive Committee of this Association held on 25th ultimo, Right Hon'ble Sir W. H. Gregory in the chair, the attention of the Meeting was called to the above case, and especially to your evidence as reported in *The Times* of 15th ultimo, to the effect that it is the custom at your Wharf to keep samples of the goods stored and to sell them on your own account. The matter is one of much interest to owners of Ceylon produce. And at the meeting above-mentioned a Sub-Committee was appointed to collect information thereon. On their behalf I write to ask if you confirm the report of your evidence; and in that case if you would kindly say for what purpose the samples in question are taken and under what rules and checks.

The custom is one unknown to several large importers from Ceylon, and however carefully guarded would seem one likely to be open to abuse.—I am, dear sir, yours faithfully,

(Signed) WM. MARTIN LEAKE, Secretary.

39 Eastcheap, London, 6th Nov.

Dear Sir,—I called to see you this morning in reference to your letter re coffee reference samples.

The custom is one so wellknown to the trade, that I am surprised to find that your Committee are not acquainted with it.

A small reference sample about a handful is taken from the sample of each pile, supplied to the selling broker. This is placed in a small paper bag marked with the rotation of ship, and pile; and kept for reference in case of any dispute after the goods are sold.

This is necessary alike for the protection of the merchant and the dock or wharf; in case of any claim arising as to quality. The merchant or importer cannot possibly be a loser by this system, as when the goods are weighed, a sample is by order of the Customs weighed against the goods equal in weight to the sample drawn.

Any further information you may require, shall be most happy to afford you.—Yours faithfully,

(Signed) ERNEST J. HUMPHREY.

W. Martin Leake, Esq.

Ceylon Association in London, 5th Nov. 1888.

To the Manager, London and St. Katherine Docks Company, and to the Secretary and Manager, East and West India Dock Company.

Dear Sir,—In the report of the recent inquiry as to the sales of samples, etc., from the New Crane Wharf there appeared evidence given by witnesses of experience and standing to the effect that a custom has prevailed at some of the wharves in London of taking samples from the goods stored and of subsequently selling them on account of the wharf owners. I am instructed to inquire on behalf of this Association whether there is any such practice in the warehouses of your Company, and whether it is customary to draw any samples from the produce committed to deare other than those drawn by order of the merchants or their brokers?—I am, yours faithfully, (Signed) WM. MARTIN LEAKE, Secretary.

London and St. Katharine Docks Company, Dock House, 109 Leadenhall Street, London, 9th Nov. 1888.

Dear Sir,—In reply to your letter of the 5th instant, I am desired to say that there is no such practice as that to which you allude in the warehouses of this Company. Samples are drawn only by order of merchants or their brokers, or, in a few cases, of Associations authorized to take samples, and are delivered to those for whom they are drawn.—Yours faithfully,

F. H. HABBEN,
Assistant General Manager.

W. Martin Leake, Esq.

Ceylon Association in London, 26th Nov. 1888.

The General Manager, London and St. Katharine Docks Company.

Dear Sir,—In thanking you for your letter of 9th instant, I am to mention that one cause of the inquiry that I addressed to you on 5th instant, as to the taking of samples at your warehouses, was that one of the witnesses in the New Crane Wharf case, George Morris, the Colonial sampler of that wharf, is reported to have stated that up to seven years ago he was in the employment of your Company, and his evidence seemed to imply that during his 22 years' experience he had known such practices as those complained of at the New Crane Wharf to prevail generally elsewhere.—I am, dear sir, yours faithfully, (Signed) Wm. MARTIN LEAKE, Secretary.

London and St. Katharine Docks Co., Dock House, 109 Leadenhall Street, London, 27th Nov. 1888.

Dear Sir,—I am desired to acknowledge your letter of yesterday, and to say that whatever Mr. Morris's evidence, as reported, may seem to imply, the facts, so far as this Company is concerned, are as stated in my letter of the 9th instant.—Yours faithfully, F. H. HABBEN, Assistant General Manager.

Wm. Martin Leake, Esq., Secretary, Ceylon Association in London.

East and West India Docks Company, Dock House, Billiter Street, London, 16th Nov. 1888.

Dear Sir,—In reply to your letter of the 5th instant, I have to state for the information of the Ceylon Association in London, that there is no such practice in the warehouses of this Company as that which you intimate in your letter. It is not customary to draw any sample from produce committed to the Company's charge, other than that drawn by order of the merchant or his broker. There is an exception though trifling in its extent. I find that it is the practice to retain an ounce or two of the first sample from each pile or quantity of coffee, as presented by this Company. This small quantity is retained as a reserve in case of dispute between buyers and sellers, and has often been found useful in the settlement of disputes, but the quantity retained is so small that what it realizes is inappreciable and the withdrawal from the pile is also of little comparative consequence.—Yours faithfully,

(Signed) J. L. DU PLAT TAYLOR.

The Secretary, Ceylon Association in London.

Ceylon Association in London, 23rd Nov. 1888.

Ernest J. Humphrey, Esq., 39 Eastcheap.

Dear Sir,—I have to thank you for your letter of the 6th instant. I am sorry I was out when you called on that day.

I now enclose for your information copies of letters received from the L. & St. K. Docks Co. and the E. and W. India Docks Co. in reply to inquiries addressed to them as to their practice in sampling the goods in their charge.

From these letters you will see that the practice with which you think my Committee should have been acquainted is not recognized, except to a very limited extent, by the great Dock Companies. We are making further inquiry on the subject.—I am, dear sir, yours faithfully, (Signed) Wm. MARTIN LEAKE, Secy.

39 Eastcheap, London, (Road) 24th Nov. 1888.

Dear Sir,—I beg to thank you for your letter enclosing copies of replies from the Dock Cos. That

of the E. and W. I. Dock Co. is identical with the practice followed by us at New Hibernia Wharf, which was based on the custom followed at the London and St. Katherine Docks Co., when our Wharf was first opened. I can only suppose that Mr. Habben misunderstood your question as he can hardly be unaware of this custom. Let any merchant having coffee at any Wharf or Dock, lately delivered send down and ask to see a reference sample, of the pile or lot actually delivered, and I will undertake to say, that if the person so sent knows his business, he will not fail to obtain an inspection of the sample so kept for reference.—Yours faithfully,

(Signed) ERNEST J. HUMPHREY.

GREEN BUG ABATING IN HAPUTALE.

From an Estate "Down the Pass," Jan. 4th.—You will be glad to hear that the field that has had the most and worst attacks of green bug, viz., No. 1, is showing signs of returning vigour, as it has a nice sprinkling of blossom on it now, and a capital one in small spike which ought to open next month. I have now hopes of a paying crop next autumn!

KURAKKAN AS A FOOD.

It seems a curious coincidence, that, simultaneously with the appearance of Mr. Borron's plea for kurakkan *versus* rice, we should find in the *Indian Agriculturist* the statement which we quote below respecting the intention of a benevolent Hindu gentleman to send a quantity of this millet, known in Southern India as *rugi* and in Bengal as *murwa*, as a gift to feed the English poor. If Dr. Kynsey and those who agree with him,—including apparently the Government Agent of the Western Province, judging by the extract from one of his administration reports quoted by Sir Arthur Gordon,—are right in regarding the use of kurakkan for food as a direct cause of the wasting and loathsome disease known as *parangi*, the boon would be regarded as a very questionable one. With all respect, however, for the opinion of the Principal Civil Medical Officer of Ceylon and those who coincide with him, we cannot help doubting the responsibility of kurakkan for a disease which is specially one of inanimation. If the wretched victims of the anomalous disease, which has committed such sad ravages in many parts of Ceylon, could get a sufficiency even of kurakkan, we suspect the disease would become less prevalent and ultimately disappear. To show how doctors differ, we have but to recall the fact that the late Dr. Dickman, an accomplished medical man and a shrewd observer recommended that the diet of prisoners in our jails should be kurakkan, because, from its ascertained elements, it must be more sustaining than the semi-aquatic grain, rice. Then our readers will see that the peasant farmers of Mysore, whose staple food is kurakkan, are described as specially robust. On the other hand rice is an excellent absorbent of fatty and nitrogenous matter, cooked with facility and easily digested. It is generally regarded, in full quantity, as the standard of comfortable living in large portions of India. Curiously enough, too, natives of portions of India, where much richer food, in the shape of legumes and wheat, is used,—such natives, when brought to work on the Ceylon railway in Mr. Faviell's time, though provided with rations of wheat and dal, after a time took by preference to rice. The statement referred to is as follows:—

A contemporary informs us that while Mr. T. N. Mukherjee was in Madras the other day he sent a large consignment of Mysore *ragi* (*Eleusine indica*) to London. During his last visit to England he had opportunities of seeing English life in all its

phases, and he is of opinion that the distress which prevails among the lower orders of the people there is of a much more painful character than is the case among the poor in India in ordinary years. He thinks that the distress can be relieved to a great extent if a cheaper food stuff be substituted for wheat and oatmeal, and brought within the reach of the British poor. Keeping this object in view he has been experimenting with the Indian millets for some time past to find out which of them will satisfy the following conditions, viz., cheapness, and cultivation capable of expansion, so that the price will not increase with the increase in demand, palatable to Europeans, and nourishing and heat-giving properties. A consignment of *ragi* has been sent to England as an experimental measure. "This grain," says the *Madras Mail*, "must, by a long course of selection, have proved itself to be nutritious food for a strong people like the Mysore peasantry in a sub-tropical climate like that of the Mysore plateau. It is also supposed that its cultivation can be increased to almost any extent if a foreign demand arises, for in the Mysore State alone there are, upwards of 4,000 square miles of cultivable waste land. The consignment now sent will be distributed gratis among some of the work-houses in London, where the capabilities of the grain as food for Europeans will be tried in different ways. All future operations will of course depend on the report received from London. Mr. Mukarji's object is purely philanthropic, but, at the same time, he thinks that India will be benefited if an export trade can be created in a cheap grain like *ragi*, which can be cultivated on almost any kind of poor soil, and which depends for its growth entirely on the rainfall."

DRUG TRADE REPORT.

LONDON, December 20th.

For many years one of the serious grievances of dealers in spices (and to some extent in drugs also) has been the habitual discrepancy, to the prejudice of the buyer, between the weights declared on the documents of purchase and the actual weight of the merchandise bought. In the spice trade especially this shortage of weight has lately become such a nuisance that at a recent spice auction a representative committee was appointed for the purpose of investigating and reporting upon the loss in weight on spices generally, and more especially on cloves, sago, and white pepper. The report of this committee has now been issued. It is signed by Messrs. Daniel R. Harvest (W. & D. Harvest), W. O. Mew (Geo. Harker & Co.), Thomas Pink (Edward Pink & Sons), Matthew Burn (Peck Brothers & Co.), Andrew Devitt (Lewis & Peat) Charles Young (Dalton & Young), Thomas E. Garrard (Garrard & Sons), and Herbert Walton (John Harman & Co.), and it declares the complaints to have been proved by the evidence produced by various dealers; adding that in the opinion of the committee much of the loss in weight is due to careless working, weighing, and improper storage, as such loss in weight is more marked in some places than in others. Should these losses still continue, the committee will feel it their duty to advise the trade to look more particularly as to the places where merchants should be advised to store their imports in the future.

CINCHONA.—For the last auctions of the year, which were held on Tuesday, a very heavy supply of bark was catalogued, consisting of

	Packages	Packages
Ceylon bark ...	2,704	of which 1,991 were sold
East Indian bark ...	535	" 419 "
Java bark ...	212	" 131 "
South American bark	874	" 275 "
Total ...	4,325	" 2,816 "

Owing partly to the unfavourable result of the Amsterdam auctions held a few days previously, and to the heavy quantity offered, it was generally thought that lower prices would rule, the circumstance that a month would elapse between this week's sales and the next

auctions being felt insufficient to impart stability to the market. The tone was at first rather steadier than had been expected, but competition soon fell off, and though towards the end of the auctions matters improved slightly, there was a decided decline in value all round, and the unit probably did not average over 1½d per lb. The following are the approximate quantities of bark bought by the various buyers at the auctions:—

	Lb.
Agents for the Mannheim & Amsterdam works	174,761
" the Brunswick works	106,107
" the American, French, &c., works	136,466
" the Auerbach works	55,866
" Frankfurt and Stuttgart works	95,956
Messrs. Howards & Sons	33,154
Sundry buyers	34,032
Total quantity sold	636,342
Bought in or withdrawn	292,241
Total offered	928,583

The following is an analysis of the result of the cinchona auctions held in Amsterdam during the present year:—

Auctions	Quantities Sold		Total net Weight in kilos.	Average per cent of Manufacturers' bark	S. Q. in Manufacturers' bark	Unit in Dutch cts. $\frac{1}{4}$ kilo.
	Cases	Bales				
Jan. 19	305	1,903	183,025	4.25	6,549	11-12½
Feb. 23	297	1,407	134,213	4.70	4,500	12½-13
Mar. 22	373	1,065	106,900	4	2,590	13
May 3	449	1,284	132,100	3.86	3,300	9½-10
June 7	242	1,279	109,130	4.20	3,609	10-11
July 12	249	1,266	118,575	4	3,815	10-11
Aug. 30	506	2,285	220,000	4.50	8,000	10½-11
Oct. 4	200	1,564	146,627	4.25	5,200	9½-10
Nov. 8	257	1,395	130,769	4.35	4,750	10-11
Dec. 13	142	1,748	154,308	4.37	5,118	9½-10
Total	3,020	15,196	1,435,647*		47,431†	

* Equal to 3,215,849 lb. † Equal to 1,674,789 oz.

COCAINE.—The market is still tending lower. Some of the German makers quote 15s 3d per oz. for crystals in bulk, and solicit offers for large quantities.

GAMBLER.—On the spot sales have been made at 27s per cwt. for good block, but subsequently 300 bales of new import sold at auction "without reserve" at 26s 9d per cwt., rising to 27s for the last lots, a partial decline of 3d. For arrival the market is firm, and owners ask more money for the comparatively small quantities offering. At the close the market is better, with sales at 25s November-December; 24s 9d December-January; and 24s 6d January-February shipment.

QUININE is still tending lower, and closes without any apparent prospect of improvement. Second-hand holders of German bulk have accepted 1s 3½d per oz. on the spot, and are offering freely at 1s 4d for forward delivery, but without much success. The makers are holding aloof just at present. Their quotations are still unchanged nominally, but they would probably be glad to consider offers. We hear it said that the holder of a quantity of Italian and B. & S. quinine, in large bulk, would be prepared to accept 1s 2½d per oz. if he could find a buyer.

THE AMERICAN MARKETS.

NEW YORK, December 8th.

QUININE has continued dull and depressed. On Saturday last the Domestic makers reduced their quotations 3c per oz. upon all packages, or, say, upon the basis of 40c in large bulk, and since then the foreign agents have revised their prices, and now quote large bulk 33c to 34c, these two values representing Zimmer's and B. & S. In the outside market supplies according to brands are offered at 31c and 32c, but the business passing is wholly of a jobbing nature, there being no interest exhibited in quantities.—*Chemist and Druggist.*

CEYLON TEA PLANTATIONS COMPANY, LIMITED.

An extraordinary general meeting of the shareholders was held at the offices of the Company, 21, Mincing Lane, Mr. David Reid of Thomanean presiding.

The Secret ry read the following notice of resolutions for the deliberation of which the meeting was convened.

1. "That the Capital of the Company be increased to £150,000 by the creation of 5,000 New Shares of £10 each."

2. "That the Directors be authorized to purchase or acquire from the Chairman and others the owners thereof respectively the following Estates in Ceylon, viz.:-

	a.	r.	p.
'Wallaha' containing	290	0	0
'Scrubs' "	139	0	0
'Tillyrie' "	756	0	0
'Alton' "	213	0	0
'Upoot' "	219	0	0

or any of them or any part thereof respectively with the buildings, machinery, implements, live and dead stock, crops, produce, stores, effects, and other property to said estates, or any of them belonging or any part thereof respectively, and the business, assets, and liabilities of the respective owners or vendors of the said estates in respect thereof, or any of them, or any part of such business, assets, and liabilities at such price or prices not exceeding in the whole £45,500 payable in fully paid up shares of the Company and upon such terms and conditions in all respects as the Directors shall think fit."

The CHAIRMAN at some length gave his reasons for recommending the shareholders to accept the offer to purchase the estates enumerated in the resolutions before the meeting. Though largely interested in the properties as one of the vendors, he felt he could satisfy the shareholders that the purchase would be much to the advantage of the Company on the terms named.

By desire of the Chairman, the SECRETARY read to the meeting the report and valuations furnished by the Company's Ceylon Manager, Mr. Rutherford. He also read a long letter from Mr. J. H. Starey, Manager of the Eastern Produce and Estates Co., and a shareholder in this Company, approving of the purchase, and also letters from other independent shareholders as planters resident in Ceylon. With these statements the Chairman left the matter in the hands of the meeting.

Mr. Tod thereupon rose, and, as a very large shareholder, expressed his approval of the purchase, believing fully that it would appreciably add to the earning power of the Company, and he begged leave to move the resolutions as set forth in the notice convening the meeting.

Mr. Reid, of Sevenoaks, supported the resolution, explaining that he had no interest whatever in the properties proposed to be acquired. He worked out the purchase solely as a transaction likely to strengthen the position of the Company, and to add to its capability of continuing to pay good dividends. There had been a difference of opinion as to the price to be paid, but by a little yielding on both sides the Board had come to the conclusion that the terms agreed upon were fair and equitable.

Mr. ALBERT DEACON said that he had listened with much interest to the straightforward and explicit statements of the Chairman, and, after having received satisfactory replies to inquiries on one or two matters, he said he accorded his full support to the proposals before the meeting, and had much pleasure in seconding the resolutions moved by Mr. Tod.

These were then formally submitted by the Chairman, and carried unanimously.

A vote of thanks to the Chairman proposed by Mr. Geo. White, and seconded by Mr. A. DEACON, terminated the proceedings.

This Company, we understand, has now 3,816 acres under tea, including the lands being opened this year. The whole extent of the Company's property consists of 5,440 acres. At the increased capital of the Company the opened land with machinery and buildings is equal to about £37 per acre, and forest &c. at 15 10s.

THE OUTLOOK FOR COFFEE.

It is just 20 years since one of the greatest authorities in the trade, Mr. W. Schöffer, published his celebrated monograph on coffee, and, in words almost identical with those used in the circular to which you referred last Tuesday, urged the necessity of such an advance in coffee prices as would check consumption, and thus save our stocks from annihilation. Mr. Schöffer's pamphlet, however, only afforded one more proof of how the most ingenious and apparently well-founded calculations can be belied by facts. Even when figures prove true, monetary and political influences may upset the soundest conclusions; and such monetary and political risks cannot be said to be entirely absent in the near future. Without discussing the estimated increase in consumption—though much may be said on both sides—and without entering into the question of "invisible stocks" (which seems, by the way, a misnomer where figures are given with such precision), it may be here observed that as telegraphs extend, the use of steamers in ocean transport increases, and the development of railways in producing and distributing countries is being daily enlarged, the ability of the world to work, year by year, with smaller stocks of everything also becomes greater. We have an evident proof of this in the very extraordinarily reduced stocks of sugar at present held in London and the Clyde. Leaving, however, these general remarks, what I desire now to show is, that if the reports from more than one trustworthy source are borne out, the crops of coffee at present being marketed in all Brazil will be much nearer 8,000,000 of bags than to 6,100,000 given in Mr. Hvistendahl's statement. The effect of such a production would not only most seriously affect Mr. Hvistendahl's figures, but also entirely upset his main conclusion, that the maximum production of Brazil was reached in 1882-83.

In illustration of the possible future I would further remark:-

1 That the most active development in coffee cultivation occurs in the rich and rapidly advancing province of San Paulo.

2 That it is estimated that a price of 50s per cwt. much more than pays the Brazilian planter.

3 That the cultivation of San Paulo is only, to a moderate extent, dependent on slaves.

4 That the climate and the cultivation in the coffee districts is suitable to European labour.

5 That the immigration of hard-working Italians, into the province is large and continuous, having been about 80,000 last year, and being likely to reach 100,000 this year.

6 That with a continuance of such immigration there is every ground for hope that the cultivation of coffee will be extended so long as prices here do not decline much below 50s per cwt.

7 That, therefore, there is no reason to fear any falling off in production, except as the result of disease or of unfavourable weather.

8 That the United States have shown us that the abolition of slavery (even when effected suddenly) can be co-incidental with a greatly increased production.—I am, sir, yours, &c.,

Mincing-lane, Dec. 6th, 1888.
—Financial News.

CEYLON TEA IN WESTERN AUSTRALIA.—Mr. H. Pierssens, who has had experience in the tea trade in London, has been on a short visit to Ceylon, and leaves by the P. & O. steamer on Thursday for Albany en route to Perth, the capital of Western Australia where he hopes to establish himself, mainly with the view of introducing and pushing the sale of Ceylon teas. We wish Mr. Pierssens all success in his new home with its fine climate and rapidly rising importance. As the pioneer of Ceylon teas in that region after he has fairly established himself and made up his mind to settle, he should in our opinion get some recognition of his enterprise from the Ceylon Tea Fund Committee.

CHARLEY VALLEY TEA.—Having tasted an infusion of Mr. De Soysa's tea, an invoice of which realized so high a price in the London market, we can testify to its superior flavour and strength, qualities which are certainly striking, if, as we suppose, the packet sent to us is a fair average specimen of broken pekoe.

GIGANTIC FEEDING ROOTS.—Here in Ceylon where mangolds are unknown and turnips weigh only a few ounces, it takes away one's breath to read what follows from the London *Times's* account of the Smithfield cattle show:—"There is as much beauty in a well-formed Swede as can be evolved by the highest art, and probably no portion of the stand could be pointed to with greater pride than a group of yellow globe mangold, grown by Lord Wantage, and with which the champion prize open to all England (given by Messrs. Ryland and Proctor) was this year won. The crop was one of 60 tons per acre. Next to this stand was that of Mr. King, of Coggeshall, and here also was a very nice lot of roots. The well-known firm of carters had a very grand display, the leading feature being the elephant swede, one of which weighed no less than 30 lb. The form was perfect and the group quite a picture."

CEYLON TEA FOR AUSTRALIA.—In reviewing Mr. Caine's new book, the *Australasian* refers as follows to our tea *versus* China tea:—"Ceylon bids fair to rival the most important districts in Northern India in its tea-growing capacity. The teas are of high character, fine flavour, and perfectly pure, and I see no reason why India and Ceylon should not in course of time supplant China teas to a very large extent." So writes Mr. Caine. In the year 1886 this colony imported from China tea of the value of £588,425, and that country did not take from us one shilling's worth of merchandise in return. The account had to be balanced either directly or indirectly by bullion. On the other hand, while our imports from Ceylon were only of the value of £45,508, our exports thither were of the value of £222,332; so that we have every reason to discourage the consumption of Chinese tea, and to encourage that of the Cingalese leaf in Victoria. The planters there are our own countrymen, and the probabilities—perhaps it would be more correct to say the certainties—are that an increasing importation of tea from Ceylon will be followed by an augmented exportation of Victorian produce to that island."

COFFEE IN EAST JAVA.—The *Soerabaia-Courant* of December 20th has the following "Malang Coffee Intelligence," dated Soerabaia, Dec. 17th:—"The reports regarding the 1889 crop are of a cheering nature; the estimates of crop are expected to be exceeded generally. The weather is favorable; rain falls daily, but not in excess. High-lying plantations are bearing heavily, so much so that props have had to be used. The whole of the 1889 crop (some 2,000 piculs) of an estate on the Smeroe has been sold during this week to a Soerabaia firm at f45, and the produce of a land on the Southern Mountains (estimate 1,500 pic.) at f42. During the 14th and 15th inst. a dull rumbling was heard in the distance, supposed to be working of the Smeroe; one may, however, be easily deceived in this, by a thunder-storm at a distance. Scarcity of rice still continues to cause many laborers to come to the estates. With regard to leaf disease nothing has been heard, which may be considered as a favorable sign. Thefts of coffee *bibit* [*bibit*, Javanese for 'seed'] took place generally towards the end of the planting season; now it seems to be otherwise, for scarcely has the planting season begun than we hear of cases, without one being able to catch the perpetrators."

MADURA CROPS.—The *Madura Mail* says, that although there has been an improvement in the general prospects of cultivation in many places in the district, the crops have been raised so late that the outturn is expected to be below the average. There are still many tracts, the major portion of the Melar Talook and the Terumar Firka in the Madura Talook, where there has been little or no rain yet, and where even the punjat crops have again failed. But the collection of rent having begun the people are in a sad plight.—*Indian Agriculturist*. [There is, therefore, likely be a large emigration of coolies to Ceylon.—*Ed. T. A.*]

GUM TREES IN ITALY.—Among many interesting items noted, Mr. Cook says:—"I am much amused to see that our old friends the gum trees are now beginning to dominate the scenery of this classic land. They soon shoot up head and shoulders above the olives and other native trees, and are rapidly transforming the aspect of the landscape. They keep up their old topsey-turvy colonial habits, and are unconsciously blooming away now as though it were really spring! The mosquitoes are at the present time very much in evidence, and seem quite in keeping with the gum trees, and, together with the swarm of flies, generally suggest very forcibly what an inferno this place must be during the fervid heats of summer!"—*E. Mail*.

CEYLON COFFEE PLANTERS scarcely want to be encouraged to fight "green bug" or do all they can to conserve what is left of our old staple; but certainly if they do want to be assured of bumper prices in the future, the news from the one really great coffee country left, Brazil, is all in favour of scarcity of produce and dear coffee. A Manchester paper has the following:—

Mail advices from Rio de Janeiro, dated November 24th, say that the increase in the receipts of coffee was apparently due to an improvement in railway facilities. Recent rains, however, seemed likely to affect the supply adversely. It will have been observed from the telegram that there has been a falling off lately. The opinion seemed to be extending that most people in Rio de Janeiro and in Santos had been too enthusiastic over the outturn of the present crop; the maximum of the latter port is now estimated at about 2½ million of bags, and that of Rio remains doubtful; if we may accept the published advices from the coffee zones, next year will prove to be one of the most unsatisfactory known in the trade. The province of S. Paulo may save the situation. It is, however, admitted that the outlook for Brazil will be gloomy if the anticipations of a coffee famine are verified.

"DESICCATED COCONUT" FROM FIJI.—In quoting the following paragraph from the *Fiji Times*, we venture to infer that "desiccated coconut" means coconut kernel so prepared as to be suitable for use by confectioners? If that industry succeeds in Fiji, why not in Ceylon?

The first illustration of a practical outcome of the Governor's suggestions, for the prosecution in the colony of some of the industries which may be successfully undertaken here, has been afforded by the export, per Gunga, of half a ton of desiccated coconut. This has been manufactured by the Pacific Desiccating Company, and has been shipped for London, through Messrs. A. M. Brodziak and Co. of this town. With a laudable desire to help the experiment by all means in their power, and thus to promote in some degree the interests of the country, those gentlemen have given their services gratuitously; a very commendable course of conduct. The result of the trial shipment will be awaited with very natural anxiety, as upon that the future of the industry will largely depend. No doubt is entertained as to the character of the returns, but certainly will do much to encourage further enterprise in this direction. The spirit displayed by the Company is much to be commended and it is to be hoped they will secure the success they so thoroughly deserve.

PEPPER CULTIVATION IN CEYLON: SUCCESS OF THE MALABAR VINES.

We tender our best thanks to Mr. Martin for his interesting contribution to the history of what we feel confident will yet be an important enterprise in Ceylon. The experience which Mr. Martin records is common to all industrial pioneers. Pepper with jak and other trees, in addition to rocks on which the vines are supported, was all that remained to the writer hereof, when cacao, Liberian coffee, cassava and other products had to be superseded by tea (now a very satisfactory success) on a lowcountry estate near Henaratgoda. Our pepper vines there look well and are growing and bearing satisfactorily; and thus encouraged we have been indenting for the best kinds. Recently we heard that cuttings prepared to be despatched from Singapore had perished, and the same fate befell several pounds of seed put into a nursery on the estate. The seed is supposed to have been rotted by over-abundant monsoon rains, a cause which will not operate again for several months. Next month or early in March we hope to receive half-a-dozen pounds of seed of best Malabar vines from Messrs. Hinde & Co. of Calicut, and we trust a fair proportion at least may be successful. Was seed true on Eden estate? and, if not, why not? We suppose cuttings are more certain to grow, and they, of course, yield quicker returns. Cubebs it seems very difficult, if not impossible, to obtain. If they once get established in Ceylon, there can be little doubt the price will speedily be reduced as was the case with cinchona bark. For the ordinary spice, black pepper and white (the latter being merely the berries bleached in preparation,) the demand in the markets of the world is large and is likely to increase to the level of production even if peace should be restored to Achin. The consumption of pepper in the United States is very large. We are glad to see Mr. Martin mentioning the jak in the list of trees good as supports for pepper vines. This tree, the value of which European planters do not properly appreciate, or so many would not have been in recent years destroyed, is the support for native sugar and yam, and both saprophytic and climbing vine seem to thrive simultaneously. Should the vines wear out and there should be no desire to renew them, the tree is valuable as a fruit bearer and ultimately as one of the very best timbers which can be used for furniture, or for other purposes. We are not familiar with the system described by Mr. Watson as pursued in the State of Assam, of putting down large numbers of timber posts to support the vines, can pay. In our own case, we find that the pepper vines do well on the same and support the rocks and boulders, and thus grown amongst tea, there is no necessity for the presence of any other supporting trees to the detriment of the single plant. Our correspondent "W. B. L." has gone further and dispenses with all support, growing his vines "gooseberry bush fashion." He is to report progress, and we see no reason why pepper vines so grown should not flourish and yield fruit as well as do grape vines. But whatever mode of culture is adopted it is important that the best variety of vine should be available for culture, and Mr. Martin's letter shows that, after much disappointment and expense, this is now the case on Eden estate, Ambalagoda.

Immediately our Manual "ALL ABOUT TOBACCO" (likely to be a bulky volume with illustrations) is out of hand, it is our intention to begin one on the spices,—“ALL ABOUT PEPPER, NUTMEGS, CLOVES AND CINNAMON” in one volume for the benefit of local agriculturists.

MARIAWATTE TEA PLANTATION AGAIN GIVES OVER 1,000 LB. PER ACRE.

The original 100 acres of Mariawatte have again, we hear, given over 1,000 lb. of made tea per acre, making the fifth year in which this has been done. From 1st of Jan. 1888 to 31st Dec. last, the 100 acres gave 1,033 lb. of made tea per acre, which, considering the poor season (so far as yield is concerned) which has been experienced this year, certainly shows that no lack of vitality is exhibited by the trees.

The following has been the yield of this 100-acre field since 1884:

1884	...	1,092	lb.	per acre
1885	...	1,178	lb.	per acre
1886	...	1,059	lb.	per acre
1887	...	1,126	lb.	per acre
1888	...	1,038	lb.	per acre

Our correspondent "Old Colonist" asked in our columns lately wishing to know what the knoll behind the superintendent's bungalow yields per acre. We have been favoured with the following information from the Co.'s manager:—"The field referred to by 'Old Colonist' was planted in June 1886, and was begun to be plucked at 22 months old, or in the month of April 1888. For the 9 months ending 31st Dec. 1888 it gave 114 lb. per acre."

The plucking area of Mariawatte during 1888, including all young tea, was 406 acres, and the average yield was 474 lb. per acre.

ESSENTIAL OIL IN TEA.—Dr. Hassall, the well-known food analyst writes as follows regarding the essential oil in tea:—"The volatile oil is not present in fresh tea, but is developed in the course of drying and roasting. It is of a lemon color, readily solidifies, and becomes resinous on exposure to the air. It is to it that the aroma is mainly due. The amount present in tea is stated to be about 1 per cent., a statement we consider to be open to much doubt. For the estimation of the volatile oil, a considerable quantity of tea must be operated upon. This must be distilled with water and the distillate received into a cool receiver. The oil should be found floating upon the water. We may state, however, that, in certain attempts we have made, we have failed to obtain any weighable amount of the oil. The distillate had the odor of tea, but no oil drops were visible." According to Mulder's frequently quoted analysis, green tea contains 79 per cent., and black tea 60 per cent of essential oil.—*Indian Tea Gazette.*

THE ORIGIN OF TEA.—The tea plant grew for endless centuries in Central Asia, and the guleless Celibates blandly assert that the drink was invented by Chin Nong some 5000 years ago. A poetic version makes it 1600 years ago, and gives the following account of the first appearance.—In the reign of Yuen Kung, the emperor of Chin, an old woman was accustomed to rise every morning at daybreak to the market-place, carrying a cup of tea in her hand. The people bought it eagerly, and yet from the break of day to the close of evening the cup was never exhausted. The money received was distributed among orphans and beggars. The people sorrowed and centred her in prison. At night she threw through the prison windows with her little vase in her hand." If you care to do so you can read this story and enjoy it in the original Chinese of the "Cha Pu," or "Ancient History of Tea," and will no doubt find the translation exact. Tea was not heard of in China again for three centuries and a half, when a "Fohi" priest was sent to the mountains of Japan as a penitent. In the ninth century an old beggar from Japan took some of the seed and passed back with him to his own land. The Japanese realized the new drink, and built at Oank a temple to the memory of those who introduced it. The temple is still standing, though now almost 700 years old.—*Oil, Paint and Drug Reporter.*

Correspondence.

To the Editor.

PEPPER-GROWING IN THE AMBALANGODA DISTRICT.

Eden Estate, Ambalangoda, Jan. 10th, 1889.

DEAR SIR,—I send you herewith a few cuttings from the pepper vines growing on this estate, to show what can be done in growing pepper of the right variety in Ceylon. The pepper on this estate was started from cuttings brought from the Malabar Coast, and, although in some of our importations only ten cuttings out of ten thousand reached the island alive, we have now a magnificent cover of pepper as fine as the best grown in any part of the Malabar Coast. This is without doubt the only successful and satisfactory attempt to grow this spice here. As support for the vines the jak tree has proved our best ally, while the goraka, which is also growing plentifully here, will be the next valuable aid. Other trees such as godapara, diyapara, milla, are also being utilized.

We started the cultivation of pepper on this estate by clearing all the small jungle, leaving the larger trees including the above-mentioned for support. The vine cuttings, after many importations from the Coast, several of the shipments being total failures, were planted three to a tree; and the result is now a luxuriant growth, of which the cuttings herewith are ordinary specimens.

More jak has been planted, and on these which are making excellent progress the young vines thrive remarkably, well growing up together with the supporting trees. Success being now assured, large nurseries were laid down, and we are now about to plant on a large scale. I trust the specimens of a product which may become of importance in many other parts of the island as well as here will interest you.

The above information I contribute in continuation of the notice which pepper has already attracted in the columns of the local papers; and if I can give any further information to intending cultivators, I shall be glad.—Yours faithfully,
J. MARTIN.

CHENA LAND FOR COFFEE.

Devacolum, Travancore.

SIR,—A considerable venture is about to be made in these hills in coffee, and, as economy has to be studied in its severest aspects, it has been decided to purchase an acreage of *cheppakad*, as secondary growth is here called. Much controversy has arisen over this undertaking, and arguments are bandied to and fro upon the prospects of coffee growing in *cheppakad*. On the one hand, old hands assert that the enterprise means ruin, for coffee will not grow in secondary growths according to their experience. On the other hand, when asked to explain why coffee should not grow in such land, they are unable to give any reason except the ladies' reply, 'cos it won't.' It seems certain, however, that, if virgin forest were available and price no object the arguments drawn from experience would cause selection to be confined to forest soil; but when there is no forest (at the proper elevation), but only this secondary growth, then we have to inquire into the why and the wherefore. That soil should be exhausted by having one crop of grain taken off it by the hillman seems extraordinary. How can heavy tilled land, although once felled and planted, lose its virtue for subsequent use by the coffee planter? It would be preferably thought that the value of the land for coffee would depend on the conditions of such soil after the jungle has grown again,

and that no dogmatic assertion such as negatives all value to such land should be admitted. A reason frequently urged against the selection of *cheppakad* is, that, as the hillman has abandoned it after 2 or 3 years of occupation, sufficient proof of its exhaustion is afforded by this practice. But, so far as inquiry goes, it is thought that the hillman abandons such land, not because its fertility is exhausted, but because it is so fertile as to send up masses of weeds which he has neither labour sufficient, nor implements to eradicate.

In other coffee countries it is noted that no such prejudice exists against replanting abandoned properties. For instance, in Java a coffee garden is planted over and over again as trees die down. So also in the Brazils and in many places where the bush is treated as a garden shrub rather than as an agricultural crop plant.

This brings me to a second much controverted question, viz., as to the distances at which coffee bushes ought to be planted, and as to the height to which they should be allowed to grow. The custom in all countries mentioned in Spon's "Encyclopædia of Commercial Products" tends to large distance planting as opposed to the Ceylon and India custom of close planting. The argument in favour of the former method rests on the greater room given to the bush, to its treatment as a fruit-yielding bush, each several plant being attended to like a peach tree at home, well-manured, watered if necessary, shaded where required; in short following the *petite culture* of the market gardener, rather than the large-acre turnip field method of raising the plant. When you have 600 or 700 bushes to the acre instead of 1,500 or 2,000, this style of caring for each separate bush can be prosecuted; and in this, say the advocates of the system, lies the secret of successful planting. They seem to go further and hint that the real cause of the leaf disease was close planting and consequent entanglement of roots generating, it is surmised, fungoid disease, which spread to the leaves and so destroyed the tree. Doubtless, however, this view of the origin and propagation of that disease has received attention from experts and has been fully investigated. "In Java estates were (in 1884) being said out 10 ft. x 9 ft. and 9 ft. x 9 ft."—*Spon's Enc.* "In Brazil an acre contains 350 trees. These are allowed to grow to 6 ft. high, and at six years they yield 1½ lb. on poor land, 3 lb. on medium land, and 4½ lb. superior land."—*Ibid.* If this means coffee prepared for the market, the crop on medium land would be 1,050 lb. to the acre, which would satisfy even a Ceylon planter! If any of your readers would kindly discuss to some extent the two points of soil and distances, it would be, I think, of interest to the many planters, who will shortly turn their attention again to growing coffee; for, after all is said and done, there can be little doubt that coffee successfully and economically grown is by far the most profitable crop that lies within the compass of the host of subjects treated of by your excellent publication. S.

THE LOCAL MANUFACTURE OF SLEEPERS.

The manufacture of the Denham-and-Olphert cast iron sleepers is being briskly carried on in the East Indian Railway Workshops at Jamalpur, the daily output being from 400 to 500 complete sleepers. This is a move in the right direction; for while it decreases the home charges, it gives employment to a large number of natives, and is the means of utilising a large quantity of Burrakur iron monthly, this use of imported iron being entirely suspended means time. The Company evidently intend to give the local manufacture of sleepers a fair trial, a Sleeper Inspector having been engaged, who is coming out from England shortly.—*Indian Engineer.*

TEA VERSUS COFFEE.

When a man like the correspondent who signs himself "Old Planter" (see page 529) makes comparisons between tea and coffee to the disadvantage of the latter, the old King or rather Emperor may well cover his face with his mantle and, as he receives that last "envious stab," exclaim, "*Memento Mori!*—then die Caesar." Considering our friend's experience, however, we cannot wonder. He and others did all that could be done for coffee in the shape of supplying fertilizing matter in the hope of counteracting the insidious fungus. But all in vain! They found they were only feeding the enemy which preyed on the lifeblood of their plants. We do not feel so certain as our correspondent and others do that the visitation of leaf disease was a direct penalty for covering large expanses with one product. What happened in the case of coffee in Ceylon as in those of the potato in Ireland and the grape vine in France was that when a blight, fungoid or insect, in the one case or the others, developed, it seized on the large expanses of favourite or exclusive food which it found ready. It is a shrewd argument in favour of "OLD PLANTER"'s new love that even if a blight did attack tea we could cut down the bushes to the roots and burn away the infected portions, with the loss of produce only during the period which the plants took to grow again,—say a couple of years! Once tea is in bearing, too, and constantly yielding crop, as it does in this climate, there is no reason why the planter should go into debt and mortgage his property: he can sell his tea month by month as he harvests the leaf, and pay as he goes. We trust this view of the culture will not be lost sight of, but that careful planters will observe it, to the benefit of themselves and those dependent on them.

"LONDON PURPLE" AS A CURE FOR GREEN BUG ON COFFEE.

"London Purple" is by no means a new remedy. It has an established reputation among horticulturists in England and the United States extending over a good many years; but we are not aware if it has ever been tried in Ceylon in connection with any of the pests which infest our plantations? If any experiment has been made either in connection with coffee grub, leaf fungus (though it is scarcely applicable being an insecticide) or its dire successor "green bug," we should be much obliged by learning under what circumstances the application was made and the results, if any were obtained. If there has been no experiment and if such an authority as the Director of the Royal Botanic Gardens thinks well of the experiment, we believe

there are several proprietors of "good coffee" both in and out of Uva, who are prepared to expend money in the attempt to fight and drive away "green bug" by applications of the strong arsenical poison known as "London Purple." The United States have hitherto been the great field where this remedy has been tried, and it cannot be said that over the vast territory between the Atlantic and Pacific oceans, agriculturists of every degree have not had their difficulties with terrible enemies, both insect and fungoid, to as great an extent as the farmers and vine-growers of Europe. By special request in 1884, we carried from Ceylon to Professor Harkness of the Academy of Sciences, California, a specimen of our then great coffee foe, *Hemileia vastatrix*, in which the worthy scientist expressed the greatest interest; but he showed us how our experience in Ceylon had been paralleled even in extra-tropical and comparatively dry America. The professor produced a specimen of the "black rot fungus" which had literally killed whole orchards of cherry trees over some half-a-dozen of the Eastern States of the Republic, so that not a single fruit-bearing cherry tree survived over hundreds of square miles. We mention this simply to show that the Americans have had experience of fungoid, as well as of every variety of insect pests, in the Colorado beetle, canker worm, codlin moth, pear slug, &c. Under such circumstances there is some reason for giving attention to a remedy which comes recommended so strongly by American planters and agriculturists of all degrees, chemists and professors. The manufacturers (Hemingway's, 60 Mark Lane, London) recommend their preparation as follows:—

"London Purple."—This powerful Arsenical Poison received the highest award at the Adelaide and New Orleans Exhibitions as an Insecticide for the destruction of the Cotton Worm, Colorado Beetle, Canker Worm, Peach Borer, Ants, Beetles, Grubs, Flies, and all similar Pests. A single application of it in the proportion of 1 lb. to the acre destroys all insect life without injuring the plant. It is strongly recommended by the United States Government, by all the State Agricultural Colleges, and also by the Indian Government, as being superior to all other Preparations.

The price is 4½d. per lb. in boxes of 1 lb. each, (100 boxes in a case—case free); or 3d. per lb. in bulk (400 lb. in casks). Among the products and their specific enemies for which "London Purple"—the planters' friend—has been used with effect are:—cotton for cotton worms, on potato beetles and several species of leaf-eating larvæ, apple worms, and orchard slugs generally. To show its application on a large scale on a plantation, we quote as follows from the American pamphlet:—one of several testimonials to the same effect:

A large planter, highly respected in his neighbourhood, writes us from Louisiana under date Feb. 2nd, 1888:—"Last year my agent concluded to try 'London Purple' in the same manner that the planters in Louisiana were using Paris Green. He made bags about 3 in. x 18 inches long (of 8 oz. Osnaburgh) attached one to each end of a common stick 6 feet long. He put a man on a mule and had this stick carried across the pommiel of the saddle in front of him—a bag over each cotton row—the motion of the mule caused sufficient poison to escape to destroy every worm on the cotton stalk. No rain fell for several weeks after and there was therefore no need of any further application of the 'London Purple.' When frost fell this cotton was growing and making, while that near by was divested of every leaf: The poison was applied to about 50 acres of cotton: The yield on this 50 acres was more than double that where no poison had been used. I had six hundred acres in cotton and estimate my loss by not applying the Purple to the entire crop at eight thousand dollars."

We think therefore that unless it can be shown "London Purple" has been already tried in Ceylon and proved a failure, there is a good *prima facie* case made out for giving it a fair trial on coffee in reference to the destruction or even mitigation of "green bug."

CEYLON UPCOUNTRY PLANTING REPORT :

MR. S. ELWOOD MAY AND THE TEA FUND COMMITTEE—MR. MCCOMBIE MURRAY AND DR. DUKE—CHOICE OF DATE IN REGARD TO THE FORWARDING OF PACKETS OF TEA TO THE AMERICAN EDITORS—"THE BOSTON TEA-PARTY"—COFFEE AND ITS CHANGED METHODS OF GROWTH—LEAF DISEASE AGAIN—THE COMING CACAO CROP AND PROMISE OF SUCCESS—THE APPLICATION OF DILUTED KEROSENE TO CINCHONA CANCKER—THE ADVENT OF THE DRY SEASON.—THE COOLY'S LOVE OF THE "FUTURE."

14th January 1889.

Now that Mr. S. Elwood May, who was to do so much for the introduction of our teas into America, has retired into private life, and his valiant henchman Mr. Pineo has thrown up the sponge, it is to be presumed that the Tea Fund Committee will feel very much more free in working out a plan for the American campaign than they have done for some time.

Mr. McCombie Murray, of course, does his best and is deserving of support; but there is the scheme of Dr. Duke, the present of a packet of tea to the editors of the American papers, which seems to me much too valuable to be shelved.

We have lost the opportunity of forwarding the present, with the Christmas greetings of the Ceylon planters; and to wait till another Christmas comes round would be a sad waste of time, in the face of our steadily increasing output. It is not necessary, like the Hindu religionist, to seek for an auspicious day; all the same, there are times and seasons, and if we can hit on a happy one, so much the better. The 4th of July is a big day in America, the anniversary of the Declaration of Independence; and, if our sample packet of tea reached the editors then, it would give them something better to write about than the usual "bunkum," which is so universally indulged in at that time. Besides this, there is a kind of historical fitness that tea should arrive on that day as a *free-gift* from a British colony when we remember how a little more than a century ago the old country forced it upon the American colonists, who had spirit and pluck enough to throw it into the sea. "The Boston tea-party," as we all know, grew into a big thing; "it was," as has been said, "the first spoken word of the new national spirit."

I have little doubt that the present would be kindly received and commented on, would become through the notices widely known, and whatever the Eastern States might do, or whatever their predilections for Oolong or other inferior stuff, there would always be the west, right on to the Golden Gate, as a likely and probable future field for the fragrant growths of Ceylon. We have ever to keep in mind the vastness of the American continent, and that although the United States are one nation yet they are many peoples. A man from Pennsylvania or Massachusetts would feel almost as much from home as we would be in Kansas, Arizona, or Dakota, and the kind of tea that might suit the one would not necessarily be acceptable to the other. Anyhow whatever day may be selected as the auspicious one for offering our gift to the American editors, or whether no special day be selected it is well that Dr. Duke's capital suggestion should not be overlooked. The Indian men are nibbling away at the American market, and it is to be hoped Ceylon won't follow that example. It is only push and pluck will do it; it is well to deliberate, but you may deliberate too long.

It is a matter worthy of attention to the fortunate possessors of coffee, how best to grow it in these days. With the changed times I incline to think that we must have changed methods, and it is very questionable if our expelled old king can by any kind of liberal treatment put on even a semblance of the strength of old. Coffee has really so little reserve force, that it can't go into training, and come out of it with advantage. What it has got to do, is to be let alone, bear what it can, have only a moderate quantity of manure to help it through its crop, but digging need not be spared. I would neither prune nor handle, and although it does give a place a most untidy and abandoned look having the dry wood of last year's crop left about, still I would leave it. When we remember that we can't live on the appearance of a place, we take more kindly to a necessary eyesore. To cultivate coffee now as we did in the old days, forcing out crop by means of pruning, handling and manuring, would simply mean snuffing it out, and the big crop that might be put on would never mature. If the little coffee that remains is to last, I incline to think that a kindly neglect will do more to lengthen its day, than attention and care.

On this side we are in again for an attack of leaf disease, but where bug is not about, the lesser evil can be endured, and then we have always that hope that the attacks will decrease in virulence, which seems like as if it will ever remain a hope with us, for as far as I can see, there is no abatement in the plague.

The cacao crop is coming in, and in some places drawing to a close. I know of estates that have done very well, and of others that haven't; but, on the whole, it is turning out better than was at one time anticipated. When we remember the rough time cacao had with last year's drought, it would have been reasonable to expect that things would have been very much worse than they are. Now the promise for next crop is fair blossom appearing very freely on trees that have not done very much at present, and later on it is to be expected that the others will be equally hopeful. The borer continues to be a bore, and wants a lot of hunting; squirting kerosene into his hole is the perfect cure. He responds at once to a fragrant bath of that kind, and comes out to see what is going on. Then you secure him and end his astonishment in a tragic death.

By the way has diluted kerosene been ever tried for *cinchona* canker? A gentleman from home was telling me that he had successfully cured canker in apple trees by this means, and was inclined to think that a like desirable result would follow a similar application to *cinchona*.

Now that the dry months are before us, and work on estates less pressing and more difficult to be had, a good many coolies are being paid off, while others are preparing to leave for the Coast. These latter do a good deal of hunting after hopeless debts, with the view to increase the cash in hand. A week is wasted in looking up a brother who owes a rupee, and has owed it for years. Of course he doesn't pay, but he gives a renewed promise for settlement in that happy future when Ramasami hopes to square. What would the coolie be without that future, and how could he exist? If it were taken from him the present would be a burden, and futurity devoid of hope.

PEPPERCORN.

VANILLA IN FIJI.

We are indebted to the courtesy of Mr. Kerr, Colonial Manager of the Mortgage and Agency Company of Australasia, Ltd., for the following copy of a report on the Fiji Vanilla Pod. This is dated 1st October, last, and is from their London brokers, Messrs. Wilson, Smithett and Co. The striking difference observable in price quotations, and which arises from the value attaching to the article when prepared by experts, and the indifference with which it is evidently regarded when it is imperfectly cured, can not fail to impress those interested in its growth and preparation here. The lesson it is calculated to convey will no doubt be utilised. The pod in question was grown near Suva, and it is evident from the report that an important addition to the industries of the colony may be made if, care be but taken and proper appliances brought into use. The brokers say:—"The bean is well grown and the perfume good; but it is imperfectly prepared and the appearance is foxy, which is very detrimental and depreciates its value. The market price today would be about 3s per lb., a similar sized bean well prepared and dark in color would be worth 16s. to 18s. per lb."—*Fiji Times*.

[After all is said, there is only a limited market for vanilla, and if Ceylon, Fiji and other colonies compete on anything like a large scale with Mauritius and Reunion, a fall of price comparable to that which over-production has induced in the case of *cinchona* may be anticipated.—Ed. T. J.]

NETHERLANDS INDIA NEWS.

(Exchanges to 4th December.)

COOLIES RECRUITING.

The Minister for the Colonies has directed the Netherlands India Government to inquire into the expediency of repealing the Ordinance forbidding the emigration of coolies from Java to foreign lands. The Minister had always objected to the measure.

COFFEE PLANTING.

A royal commission has been appointed to inquire into the best means of checking the falling off in Government coffee cultivation in Java and Sumatra. The cultivation in question is carried on by compulsory labour on the part of the natives. They, in fact, pay a labour tax instead of one in coin. The cultivators get about one quarter of the market price for the produce delivered at the Government storehouses. The Government sells it, and raises a large revenue by the article. The commission has to consider how the compulsory cultivation can best be extended to the advantage of both the people and the Government.

SUGAR.

In the *Batavia Nieuwsblad* Mr. N. P. Van Den Berg, an expert in such matters, estimates the sugar crop in Java last year at upwards of six and a half millions of piculs, the largest crop since 1884. Both quantity and quality have decidedly improved of late owing to the hard times, which have compelled planters to cast about for means to economise working charges as much as possible, by greater efficiency accompanied by reduction in expenditure.—*Straits Times*, Dec. 21st.

PERAK AND TEA CULTIVATION: CEYLON PLANTERS TO THE FRONT.

Some idea how tea cultivation has gone ahead in Perak may be gathered from an advertisement in the *Government Gazette* of that protected State. The notification announces that teas manufactured at the Government Tea Factory there are on sale at prices varying from 60 to 65 cents per pound; and it is now arranged that samples of Perak tea may be had at the store of John Little & Co. for trial. Tea cultivation has made such strides in Perak that it is said enough of the article can now be turned out to supply the demands of consumers in the Straits Settlements. Coffee, too, has been grown with success at the Government experimental gardens in the Perak mountains at the prompting of Sir Hugh Low, who may be congratulated upon the satisfactory results achieved. The fact that coffee of the finest quality may also be grown in Perak, without any great danger from leaf disease, will no doubt give a needed push to planting enterprise in that direction there. Already has there been an increase in clearings for Arabian and Liberrian coffee. Tobacco and pepper are other staple products under cultivation in that promising state—Messrs. Hill and Rathborne, for instance, intend going in largely for tobacco. Then Sir Graeme Elphinstone is expected there this year to push on clearings for coffee and tea, for which he has a large capital at his command. European tea ventures are doing well on the mountains, where the cool climate admits also of the ready growth of English vegetables. Eastwards towards Pahang lies Cameron's Plateau, with one hundred thousand acres of available land for planting purposes, besides stores of mineral wealth. No doubt Perak has a bright future before it, and may yet become not only a field for remunerative enterprise, but also a much-frequented health resort.—*Straits Times*, Jan. 4th.

Even in the Malay Peninsula, tea-growing enterprise is coming to the front. It has been tried in Johore with fair success and now the experimental introduction of tea into Perak is so far developed that the time has now come when the promoters of the cultivation deem it right to assert the claims of the Perak tea as a marketable commodity of merit. The last *Perak Gazette* announces one thousand pounds of tea for sale, manufactured at the Government Tea Factory, under the supervision of Mr. J. F. M. Cock, Superintendent of Government Plantations. The economic value of the Experimental Gardens in Perak is testified to by the ready way in which its operations are being turned to practical account. Their success in promoting and affording facilities to the higher forms of agricultural enterprise has amply justified all the expenditure of time, energy and capital that has been laid out upon them under the direction of Sir Hugh Low. Planting industry in Perak is deriving much encouragement from the solid results achieved under the liberal auspices of the Government of that State. The most recent Annual Reports contain abundant proofs that coffee growing has a prosperous future before it on the sunny slopes of the Perak hills, and from the excellent results lately obtained with tea, it is to be anticipated that Perak may in years to come yet find in tea a prosperity not much less substantial than it is now deriving from tin. There is no reason to believe that in soil and climate there are

less suitable conditions for tea cultivation in Perak than those of the most favoured spots where this valuable production is grown. It is expected with confidence that a particularly well-adapted region for the growth of tea, coffee and other products exists in a large plateau first explored and described by the late Mr. W. Cameron. This plateau is on the central range between Sungai Raya and Kinta, and consists of a large tract of excellent land gently sloping to a river running through it. It stands at an elevation of between four and five thousand feet and the Sakeis who dwell there would be found exceedingly useful in the work of clearing it. Perhaps this more than any other part of Perak promises to be the scene of active and profitable planting enterprise, and we trust that Perak tea may be before long a familiar name in the list of commodities produced in this quarter of the world.—*S. F. Press*, Jan. 4th.

MR. GIFFEN ON THE FALL IN PRICES.

The interesting paper read by Mr. Giffen before the Statistical Society on Tuesday has two aspects,—a scientific and a popular. It is in the latter aspect only that we propose to deal with it. Many of Mr. Giffen's speculations are of a highly recondite order. They deal with the obscure laws of obscure phenomena. But there are others which relate to very plain facts indeed,—to the rate of wages, to the price of commodities, to the purchasing power of the medium in which wages are paid, and commodities bought and sold. These are matters in which every one of us is more or less concerned. At least, he whom they do not concern must be exceptionally rich or exceptionally destitute.

Mr. Giffen approaches his subject with the advantage that belongs to a seer whose predictions have come true. "If the test of prophecy be the event," he says in reference to a paper read ten years ago, "there was never surely a better forecast." The world, he then suggested, "was about to witness an appreciation of gold,—a rise in its purchasing power measured by commodities." Since that time prices have everywhere been falling. It hardly signifies what the goods chosen for comparison are; between 1873 and 1888 the difference is great, and it always points in the same direction. Is it pig-iron,—the figures for the two years are 127s. and 41s. 11d. Is it coals,—they are 30s. and 17s. 9d. Is it wheat,—they are 55s. 11d. and 31s. 9d. Is it beef,—they are 3s. 10d. and 2s. 8d. Is it cotton,—they are 10d. and 5½d. Is it wool,—they are £23 and £11. Is it sugar,—they are 21s. 6d. and 13s. 3d. "Measured by staple articles, no matter how we select them, gold is found to have increased its purchasing power." The sovereign buys more than as much again as it bought fifteen years ago.

As to the connection between the diminished supply of gold and lower values of commodities, the case is perfectly clear. In the fourteen years ending 1871, the excess of gold imported into the United Kingdom over the gold exported was sixty-seven millions, being an average of about five millions yearly. In the sixteen years following 1871, the excess was a little short of twenty millions. "Allowing for the increase of population, the excess of imports in the second period, to correspond to the excess in the first period, should have been nearly eighty millions; actually it has only been £11,438,000." Thus, there is some twenty millions less gold than there was in 1871 to do the same work. With this fact in view, there can be no need to go further into the cause of low prices.*

A very sweeping conclusion, surely. Most of us will feel inclined to regard the over-production of commodities as a more potent factor in lowering prices than the appreciation of gold by its limited production and the large demoralization of silver.—*Ed. T. A.*

Will this state of things last? Mr. Giffen is of opinion that, as regards the purchasing power of gold, it will last. Since 1872, the area of gold-using countries has been increased by the addition of Germany, the United States, and Italy; and as nations become richer, the adoption of a gold standard will become more general. There is more money passing from hand to hand, and then "the mere weight of silver makes it inconvenient for all concerned to handle it to the necessary amounts, if it is used at all in the daily transactions of life." Then there is a great deal of gold used in the arts—two-thirds of the annual production, Mr. Giffen says, goes in this way—and this, again, tends to increase as nations get richer. The only thing that can be looked for on the other side, is a discovery of new mines. But, to be of much avail, the new mines must be unusually rich; they must yield an addition of ten or twenty millions to the ordinary supply. As there seems no sign of any gold discoveries on this scale, we must seemingly make up our minds to see things remain as they are. Mr. Giffen does not disguise the fact that this deficiency of gold, and the consequent low prices, are far from being unmixed goods. "The redistribution described spells ruin to individuals and classes." Landlords are an example of this. To them the fall of prices means a diminution of the gross money return. The charges on the land remain the same; consequently, the whole loss falls on the landholders. Moreover, to communities in some stages, where the population is small or stationary, the same thing may be true. Mr. Giffen is not easy about some of the Australasian Colonies, or about the Argentine Republic. That the pile of debts has to be paid, principal and interest, in appreciating money, is a most serious consideration; but we are saved from these dangers in England by the steady increase of our population.—*Spectator*, 22nd Dec.

JAVA BARK AND QUININE.

This week's mail has brought us particulars regarding the exports of cinchona bark from Java during the season which closed on June 31st, and we are thus enabled to place on record additional figures bearing out the view which, in common with our Amsterdam correspondent, we have always expressed as to that island being the keystone of the position of the cinchona, and consequently of the quinine, market. In our market report we publish the figures of the last five seasons in full, and it will therefore suffice to repeat here that between July 1st 1887, and June 30th, 1888, the Java exports reached a total of 3,492,913 Amsterdam lb of 495 grammes, or a fraction under half a kilo. each. The equivalent of this quantity in English weight is 3,809,049 lb against 12,060,478 lb. shipped from Ceylon during the twelve months ending June 30th last. In bulk, therefore, the exports from the British colony exceed those from the Dutch dependency more than threefold; but much of this discrepancy disappears when we calculate the approximate alkaloidal value of the shipments. Taking our reports of the Amsterdam bark auctions as a guide, we find that the average percentage of quinine sulphate represented by the manufacturers' bark ("druggists'" cinchona may be left out of consideration) auctioned in that city during the present year has been as follows:—

	per cent.		per cent.
January	19 = 4.2	July	12 = 4.0
February	20 = 4.7	August	30 = 4.5
March	22 = 4.0	October	4 = 4.2
April	18 = 3.5	November	8 = 4.3
June	7 = 4.0		

or a general average of 4.16 per cent. It is, therefore, fair to suppose that the total of the Java ex-

ports last season represented fully 2,535,000 oz. of quinine. The Ceylon shipments, at an average of 2½ per cent., which is no doubt as near the mark as any estimate that can reasonably be formed, are equal to 4,342,000 oz., or only about 1.7 times more than the yield of the Java bark; and as the average standard of the barks offered at the Amsterdam sales is steadily rising, and the exports from Java, according to reliable accounts, are likely to assume much larger proportions in 1889-90, we feel justified in saying that in the course of possibly one, but more probably two seasons, Java will take the lead of Ceylon as a bark-producing country. With regard to the alkaloid, we find that Ceylon and Java together in the year ending June 30th last produced 687,700 oz. of quinine sulphate. British India in 1886-7 exported 1,286,900 lb. of bark, and placing her shipments for the succeeding season (of which no official returns are yet to hand) at the same amount, averaging 2½ per cent. quinine sulphate, we obtain another 515,000 oz. The shipments of cultivated calisaya from the Bolivian plantations have been very heavy lately, and if maintained at the same rate may (though official statistics from these regions travel slowly) add about another 1,250,000 lb. of bark to the year's production. These barks realise high prices at the auctions, and probably average not much under 4½ per cent. of quinine; a year's shipments from that quarter thus counting for some 890,000 oz. in the entire production. Even assuming, therefore, that the Java and Ceylon shipments will not be larger during the present season than they have been in the last, we may fairly calculate that during the year ending June 30th 1889, the equivalent of about 8,300,000 oz. of quinine sulphate will be produced, a quantity nearly 20 per cent. in excess of what is generally thought to be required for the world's annual consumption. Does it not, therefore, seem quite likely that, barring unforeseen circumstances, we shall witness "shilling quinine" in the course of 1889?—*Chemist and Druggist*, Dec. 15th.

THE PROGRESS MADE BY COTTON-SEED.

Was ever there a history, this side of Cinderella, of the uprising of humility like that of the cotton-seed? See!

For seventy years despised as a nuisance and burned or dumped as garbage.

Then discovered to be the very food for which the soil was hankering, and reluctantly admitted to the rank of ugly utilities.

Shortly afterwards found to be nutritious food for beast as well as soil, and thereupon treated with something like respect.

Once admitted to the circle of farm husbandries, found to hold thirty-five gallons of pure oil to the ton, worth in its crude state \$14 to the ton, or \$10,000,000 for the whole crop of seed.

But then a system was devised for refining this oil up to a value of \$1 a gallon, and the frugal Italians placed a cask of it at the root of every olive tree and then defied the Boreas breath of the Alps.

And then experience showed that the ton of cotton-seed was a better fertilizer and a better stock when robbed of its thirty-five gallons of oil than before.

And that the hulls of the seed made the best of fuel for feeding the oil mill engine.

And that the ashes of the hull scooped from the engine's drift had the highest commercial value as potash!

And that the "refuse" of the whole made the best and purest soap stock to carry to the market the perfumes of Laiton or Cologne!

About this time we began to spell cottonseed with capital letters.

And how it travelled abroad in its own "business"! As brand cake, it witnessed the marriage of a prince and with woody thorns and it adorned the festive entrance to the oaks; it spouted on the streets to the Dutch in hand, it glistened in the oaks of Paris as olive oils under seals and signatures; it coasted even

pronounce to save its life, and from under the dykes in Holland it went forth to parade in all the bravery of butter and buterine.

In our own country it renewed the wasting strength of Southern fields, and clad them with whiteness that would shame the fleeces of England, or yellow that would pale the fleeces of Argonnats. It knocked the Western hog into spots, and poured the West-ru lard out of the frying-pan into the fire.

And about this time Congress jumped on to cottonseed with both feet, and proposed to check its further career by a prohibitory tax.

And now comes a gentleman of this city with a process by which he extracts thirty gallons of fine oil from every ton of cottonseed meal after the oil mills have done with it. In the "tailings" of the oil mills he finds this unexpected and ample store, which he deftly extracts with naphtha, leaving the meal more nutritious as food for beast or field than before he took \$10 per ton from it.

More than this, it suggests the splendid possibilities yet undeveloped for this rural Cinderella that has risen all so swiftly from the ashes and the waste heap.—*Atlanta Constitution*.

BORNEO TOBACCO.

Writes the *Financial News*:—In the finest qualities of tobacco leaf the Dutch have hitherto possessed a monopoly, and what it is worth to them may be inferred from the fact that three shillings per pound is a not uncommon price at the Amsterdam sales, while a Virginia planter is thankful for ninepence or a shilling per pound. The reason of this wide difference is that tobacco grown in the Dutch colony of Sumatra has special qualities to be found in no other leaf. It is best fitted of any for what the trade call "cigar wrappers," being both silky in appearance and neutral in aroma. Seven or eight years ago Sumatra tobacco was almost unknown in the States; last year it was imported to the extent of five and three quarter million pounds. There are rumours of its even having found its way to Cuba, and come back again as the sheathing of genuine Havanas. Wherever it goes it is a highly appreciated article, and, so far, it has defied competition. The trade, in short, is so prosperous that it had outgrown its native island of Sumatra, and overflowed into the adjoining island, or rather continent, of Borneo. First, the Dutch planter led the way, and then Englishmen followed. The latter received an incalculable advantage in the chartering of the North Borneo Company, which, it may be remembered, caused some excited discussion a few years ago. Whatever doubts or suspicion may have been felt at its birth the North Borneo Company is rapidly living down. It has justified its existence by the energy and breadth of mind with which it has conducted its administration. Grants of land have been given to cultivators on very liberal terms. Every encouragement has been afforded to the introduction of capital and labour on its lands, until at last it is reaping the fruit of its enterprise in a general rise in values. Its managers have taken special interest in tobacco culture, and already two companies have been formed under its auspices for that purpose. The first, which was founded a few months ago, has been a great financial success, and its shares now stand at a considerable premium; a second, the Tobacco Company of British Borneo, is now under subscription. It has been organized by a strong combination of Singapore, Penang, Amsterdam, and London. Englishmen ultimately acquired, with the Dutch trade in all its branches, the sole and entire monopoly of the North Borneo Company, and have arranged to divide the profits of its business among themselves. The Dutch have for some time been engaged in a similar enterprise in Borneo, and it is not unlikely that they will eventually be able to compete with the English in the tobacco trade of the island. The Dutch have, however, been very successful in their tobacco culture, and it is not unlikely that they will eventually be able to compete with the English in the tobacco trade of the island. The Dutch have, however, been very successful in their tobacco culture, and it is not unlikely that they will eventually be able to compete with the English in the tobacco trade of the island.

average Sumatra price, and the importers have been assured that with better sorting its market value may be still further improved. This is evidently a good opening for British capital, and, without risk to the most conservative of investors, we may wish well to the Tobacco Company of North Borneo.—*L. & C. Express.*

CROP EXPERIMENTS.

The acting director of land records and agriculture in Bombay has issued an exceedingly able and businesslike report on crop experiments in the Bombay Presidency during the past year. The accounts of detailed experiments sent in by the officers of the department are subjected to a searching scrutiny, and many defects in method and calculation are pointed out: while in two appendices written by himself, Mr. Muir-Mackenzie formulates some useful rules, and lays down the general principles which should guide officers in the important experiment designed to ascertain the cost of cultivation. Among the many moot questions in Indian agriculture there is none involved in greater doubt and obscurity than this, and though a good deal of allowance must be made for the many difficulties which surround the investigation, much of the prevailing uncertainty is attributable to the lack of uniformity in the methods of different experimenters, a want of care on the part of many, and a haziness regarding the proper principles which should regulate the inquiry on the part of all but a very few. Take, for instance, an experiment made by an Assistant Collector in Satara. It was a case of a family of nine living on a holding of thirteen acres. The Assistant Collector estimated the value of the crops at R103 As. 5, and the total cost at R62 As. 9, leaving the net outturn for the support of the family R40 As. 12. Two of the adult men are said to have lived by outside labour: but even allowing for this, and for R35 said to have been contributed by the four men from their extra earnings, we have only a total of R75, out of which R15 were given towards the expenses of a marriage, leaving R60, or R9 per head, for the support of a family of seven, which, Mr. Muir-Mackenzie remarks in so many words, is absurd. "The probability is that the charge for cultivation is over-estimated, and the earnings apart from cultivation are under-estimated. The bullocks were probably lent in exchange for labour of the adults, while the manures also probably cost much less." It should be remembered that this ascertainment of the cost of cultivation is more than a mere statistical fad: for until we succeed in attaining a tolerable degree of accuracy in the quest, we can neither form just conclusions regarding the actual state of the cultivating class, nor answer with confidence the critics who declare that the Indian peasantry are in a state of starvation. For these reasons the general principles Mr. Muir-Mackenzie lays down deserve to be attentively studied by all agricultural officials. Incidentally the case of the Satara ryot family, to which allusion has been made, affords a striking illustration of the enormous burden which the prevailing marriage customs place upon the Indian peasantry. The total value of the whole of the crops raised on the family holding in the year is only R103; yet for one marriage the family gave R15 of this R103 and borrowed R60 besides! Under such circumstances for the ryot to better his condition is a sheer impossibility.—*Pioneer*, Jan. 4th.

[What strikes us is the entire absence of any allowance for dairy products in the support of the ryot family. Surely there was at least one cow yielding milk and butter?—*Ed. T. A.*]

USE OF RICE.

This country is the largest producer and one of the smallest consumers of rice among civilized countries. A comparison with the consumption of this grain in Great Britain seems to show that its use is steadily extending in that country and as steadily declining

in the United States. Following are the figures of rice consumption per capita here and in Great Britain: Great Britain, 1886, 10.76 pounds; 1885, 7.43 pounds; 1884, 9.70 pounds. United States, 1886, 3.55 pounds; 1885, 3.62 pounds; 1884, 3.90 pounds. The relative estimation in which it is held in the two countries is aptly shown by the fact that in Great Britain it is used mainly as an article of food, while in the United States a large portion is used in making beer. That prices have but little effect upon the figures and consumption is shown by the low price now ruling. It is thought that the real reason of the light demand for rice in the United States, is that in the greater portion of this country the art of cooking rice is absolutely unknown. This is more especially the case in the North and West. The consumption is greater in the South, where the mode of cooking is understood. The commercial value of this cereal is well known. Louisiana is especially interested in rice culture, and an improved demand for rice as an article of food would help the rice-growing interest of that State. It is suggested that the public needs to be enlightened as to rice as an article of food in order that the demand for this home product may be increased.—*N. Y. Record*, Sept. 17, 1888.

The above is an inexcusably careless, inaccurate and misleading statement. It is undoubtedly true that this country is the largest producer of rice among civilized countries, as the article is not cultivated to any extent in any other civilized country. The impression, however, given by reading the *Record's* statement is that the United States is a leading producer as compared with other rice-growing countries.

Let us see about that. China, Japan, the East Indies and adjacent islands are estimated to raise yearly two hundred and fifty billions (250,000,000,000) of pounds, against an average production in the United States yearly for the past three years of 150,000,000 pounds, or about one-seventeen-hundredth of the crops of the East.

The export of rice from various Eastern ports has averaged yearly for the past five years 1,892,943,808 pounds, and for the year 1887 was as follows:—

	1887.—Pounds.
Burma	1,516,704,000
Siam	141,120,000
Bengal	109,760,000
Japan	74,368,000
Saigon	56,000,000
Java	38,819,200
Madras	8,245,440

Total 1,945,016,640

The total production in 1887 in the United States was 156,088,890 pounds, or a trifle over eight per cent. of the quantity exported during the same year from the East.

The consumption of rice in the the United States is restricted by reason of its high cost as compared with the price in the United Kingdom, where it sells for less than half the price charged here. And yet the quantity of rice consumed in the United States is not much less than the total quantity consumed in the United Kingdom, as the following table shows:—

	1887.	1886.	1885.
Consumption—	Lb.	Lb.	Lb.
United States	246,158,927	252,237,415	229,812,233
United Kingdom	286,908,160	398,298,880	272,063,680

In 1887 the per capita use of rice in the United Kingdom was 7.64 pounds. The quantity varies widely from year to year, we finding it as low as 6.72 pounds in 1870 and 16.09 pounds in 1881. During the three years 1885, 1886 and 1887 it was 7.43 pounds, 10.76 pounds and 7.64 pounds respectively. In this country the per capita consumption averaged a little over 4 pounds yearly for the past three years.

The *Record* states that in Great Britain rice is used mainly as an article of food, while in the United States a large portion is used in making beer. Domestic rice does not enter into the manufacture of beer in this country, the only sort used being granulated, imported rice, the quantity of which imported averaged 41,240,089 pounds yearly for the past

three years. Assuming that it was all used for manufacturing purposes, it leaves 204,829,436 pounds, or over 83 per cent as the average annual consumption of rice as food.

In England it is quite extensively used in making beer, but to what extent is not definitely known.

During the period from 1850 to 1860 this country exported annually an average of one-fourth of the production, while at present the exports of home-grown rice are less than three-tenths of 1 per cent. of the average annual yield.

That fact lends color to the statement of a leading factor that "rice is the missing link required to give the United States a stronger hold upon the commerce of the world." It is certainly true that we buy sugar and coffee extensively in Central and South American countries, and that those countries obtain their rice supply through European factors in foreign vessels. We find that the exports of Indian and other sorts of rice cleaned in England and sent to countries the exports of which belong absolutely to the United States by geographical position, averaged 180,954,686 pounds annually for the past five years, or 30,000,000 pounds beyond the present domestic consumption of this country.

Besides the above-named shipments England exported during the same period an average of 170,000,000 pounds of rice yearly, of which a good proportion should be included in the commerce of this country.

This trade in rice can be had if uncleaned rice is admitted duty free, which advantage would develop a new industry in cleaning rice in this country and give American vessels employment in carrying rice from the East to be cleaned here instead of in England, afterwards to be transported to South America and the West Indies and exchanged for coffee and sugar to be brought back in the same vessels to supply our own wants and possibly those of other countries.

The following table shows the exports of rice from England for three years, and emphasizes the feasibility of the proposed policy:—

EXPORTS RICE FROM ENGLAND.

Destination—	1887.	1886.	1885.
West Indies	113,113,609	164,214,100	156,121,449
South America	29,977,920	26,062,400	22,830,080
Other Countries	100,927,529	159,254,200	170,692,489

From the foregoing it can be seen that rice is of growing commercial importance to this country; that rice cleaned in England, if not trebled, home consumption, without serious injury to domestic growers. It is no wonder that a combination of capitalists is being made, looking to making this country a leading rather than an insignificant factor in the distribution of the rice crops of the East. Cheaper rice is the shortest road to making the United States the largest consumer in Europe or America.—*American Farmer.*

ON THE TRUE VALUE OF GUTTAPERCHAS SUPPLIED BY THE "MIMUSOPS" AND THE "PAYENA" FAMILY OF THE SAPOTACEÆ.

By Messrs. EDOUARD HUBER and FR. SCHLAGDENHAUFEN.

The question of the guttapercha supply being still pending in face of the increasing destruction of the *Landolphia* in the Sunda Isles, and the imminent disappearance from the forests of that vegetable, it seemed to us that it was of great interest to call attention to the similar products obtained from the numerous representatives of the *Sapotaceæ*.

Some years ago we received from Mr. Jaubert, a Frenchman who became a merchant in Manila, King of China, and M. Kummel (Hochst), a good deal of a gutta product which was witnessed by the botanical samples we had ordered from the *Mimusops* Station. Besides, we received from an officer of the French Navy, who had been living in the Sunda Isles, another kind of gutta, which we assumed with certainty to be the same.

Since a product identically similar to the latter was supplied to us abundantly by Mr. Thomas Christy, the

well-known learned London druggist, who told us that he had several tons of same in stock. The first gutta (from *Mimusops*) which I shall call Abyssinian, appears in the aspect of a hard dirty-brown mass; but not as dark as the genuine gutta (from *Landolphia* Gutta) of the trade. It is easily marked with the finger nail, and if kept in the hands in softens readily and sticks fast to the skin; but adhesion does not increase with heat.

The other one (from Sunda Isles) appears as a white-yellow mass, equally hard, more easily marked with nails than the former, at least, more adherent to the hands which softened it by their own heat.

All the samples Mr. Thomas Christy received assumed the form of round balls, weighing about 150 to 200 grammes, rather irregular and flattened on some places, so as to be like a recently picked potato.

From the physical description we now pass to the chemical examination of these products.*

I. Abyssinian gutta (from the *Mimusops Schimperii*; and M. Kummel), (Hochst).

We treated the material first with tepid water, and afterwards with boiling water, in order to separate as well as possible the vegetable rubbish and other impurities. Allowing then the liquid to cool, and strongly stirring the greyish sediment, we have been able to fix to the agitator a material of the same colour, more or less elastic, quite different to the non-adhesive clotty sediment which remained at the bottom of the capsule.

Notwithstanding the various treatments repeated in hot water and extended stirring, we did not succeed in agglutinating that last part. The cause of resistance to plasticity was the large quantity of fixed salts contained in the sediment, since an analysis made on 0.627 of the material shows us 0.127 of ashes. The sediment which falls at the bottom of the water contains, according to these data:—

Organic matter	72.56
Ashes	27.44
	100.00

The adhesive and elastic matter, of an earthy-brown colour, was then worked up with the finger into an homogeneous mass. This offers some analogy with the common gutta as to external appearance; it softens in water, but keeps a very great elasticity, and remains exceedingly adhesive. On account of these defects it can never be used in place of good commercial gutta, without previous modifications or transformations.

Many trials were made in order to cause these inconveniences to disappear, or, at least to decrease, but always unsuccessfully; sudden changes of temperature and pressure gave negative results. We then made an attempt at mixing it with ordinary gutta, in the hope that the excess of elasticity and adhesiveness might be attenuated by the plasticity of gutta of the best quality.

For that purpose we made two mixtures:—The first one (A) with one part of Abyssinian gutta and two parts of commercial gutta; and the other (B) with equal parts of each. We gave both of them to the manager of Messrs. Berger-Levrault's printing office, and asked him to let us know if, in this state, the new product might be used in the trade; for instance, in taking casts of copper-plate engravings intended for electro-typing. The experimental gave excellent results. In order to detect the cause of such a difference between these two varieties of gutta, we sought how it behaved towards some chemical agents. Our first trials were made, of course, with the solvents like alcohol, ether, sulphide of carbon, etc., etc.

While alcohol does not dissolve common gutta, the matter subjected to the analysis was dissolved at the rate of 42 per cent. The solution obtained with the boiling liquid is colourless. It leaves, after cooling, a white deposit of a crystallized aspect, an effluvia crystalline appearance. The other two dissolves

* In connection with this subject, our readers should refer back to the article on pseudo-gutta, in the *Tropical Journal* for September, 1888.

really some few needles, which cannot be removed by any of the excipients we used for that purpose. We think, then, that the substance in question is amorphous, but, however, has some tendencies to crystallise. By taking it up again two or three times with boiling alcohol, it is possible to get it, at least, snow-white; the compound of the resinous kind is fusible at 107° centigrade. If heated until 230° centigrade it keeps up melted without the slightest alteration, but at a higher temperature it darkens, and becomes decomposed. It is soluble in common alcohol, methylic alcohol, acetone, naphtha, chloroform, ether, turpentine, petroleum ether, and "sulphide of carbon." It does not dissolve in boiling potash, and does not give decomposed products under the action of melting potash. Nitric acid destroys it very quickly, and gives rise, among other things, to a crystallised body, and to some oxalic and picric acids.

The formula of the compound is: C_5H_8O , or $C_{20}H_{32}O_4$. This substance can be regarded as a product of oxidation of *Albane* ($C_{20}H_{32}O_2$) contained in common gutta, but it is different as to the chemical properties. Besides, it possesses none of the characters of the *Fluavile* ($C_{20}H_{32}O$) which follows *Albane* in the common gutta.

These two resins, the first of which is crystallised, the other one amorphous and translucent, are mixed in the gutta according to the following ratio:—

Gutta	75	to	82
Albane	19	to	14
Fluavile	6	to	4
					100		100

Whilst our *Mimusops gutta* contains only this white uncrystallisable resin, from which we just gave analysis, and which forms 42 per cent. of the raw material. The remaining, *i.e.*, 58 per cent. of matter, insoluble in alcohol, is a dark brown mass, somewhat like common gutta, and which, like this, is soluble in sulphide of carbon, very little in ether, and quite insoluble in common alcohol, methylic alcohol, and acetone. That matter contains 9·80 per cent. of fixed resin, nearly all from some sulphate of lime. The compound of *Mimusops gutta* can be then represented as follows:—

Gutta	48·20
Fixed sorts	9·80
Amorphous resin	42·00
					100·00

The raw product, as well as the refined gutta, after eliminating all, or partly, that resin, can be used as we said before. The mixture suitable for electrotyping can be obtained by boiling the raw material with equal weight of alcohol at 90°. It is then filtered, and the remaining mass is mixed with equal weight of commercial gutta.—*Indiarubber and Guttapercha Journal*.

COFFEE IN JAVA.—Amsterdam, Dec. 19th.—Disquieting reports are being received with regard to the serch disease among the coffee trees in Java. It is said that the disease is generally assuming greater proportions, and that measures have to be taken to avoid a further extension, which would result in a total ruin of this large and remunerative cultivation. A trial made on a large scale by private planters in Kediri with the prick method, recommended by Dr. Burek, which is comparatively not expensive, must have given satisfactory results. Dr. Burek has been charged by the Java Government with a tour of inspection through Java, and it may be expected that the Government will soon order the introduction of effective remedies to check the disease. According to private information, confirmation of the report is required, as the large colonial banking institutions here have not yet been advised of the extension of the serch disease.—*L. & C. Express*.

PEPPER PLANTS FROM SEED.—Having in our article on pepper culture stated that 3 lb. of pepper seeds were sown in nursery beds on a lowcountry estate, we feel bound to quote as follows from a later report just received:—"The fine weather has germinated the seed which I thought had gone bad, and a good many plants are now come up."

Messrs. JOHN LITTLE AND Co. have sent us a sample parcel of Perak Tea grown and prepared at the Government Plantations in Perak. The qualities produced are various, chiefly Pekoe and Pekoe Souchong, and are put up in convenient parcels up to 2 lb. Any of our readers desirous of giving this tea a trial may have a sample 2 oz. packet by calling at Messrs. John Little & Co.'s. We have been kindly furnished with a few sample packets for distribution to friends visiting this office, whose opinion is invited upon the new growth. As we daily oscillate between the harmless decoction at the "Caravanserai" and the nerve-destroying brew of the "Club" we have extreme difference in our own powers as a tea-taster of authority. The verdict of the more discerning palates of lady friends is therefore desirable in order to decide upon the merits of the new tea.—*S. F. Press*, Jan. 4th.

RAID AGAINST THE SENSITIVE PLANT IN FIJI.—We in Ceylon are aware that next to *lantana* the *mimosa* known as "the sensitive plant," has of all introduced plants the power of spreading itself. In Fiji it must be a serious evil, interesting and beautiful as it is, for we read in the *Fiji Times*:—"The Governor having noticed the alarming increase in the spread of the sensitive plant in Levuka, has sent over instructions directing that steps be at once taken in Suva in order to eradicate that noxious weed. In pursuance of those directions, a gang of twenty prisoners has been employed in the task of destroying it, and they have been busily at work in the endeavour, with the effect that it has been cleared from at least the more prominent positions in the places where it had taken hold. But that any real good may be effected, the destruction must be thorough; as, otherwise, the well-known tenacity of this pest will but render operations useless. It should be dug up and burnt, and no vestige left; its extraordinary power of reproduction rendering anything like half measures absolutely ineffective. It spreads with wonderful rapidity; and, from a single seed, a crop, marvellous in its growth, has been known to spring. It has been a nuisance for years in Levuka."

THE GREAT DRAWBACK TO THE CULTIVATION OF GRAIN, chiefly paddy, not in Jaffna only, but throughout the Northern Province is the long spell of dry weather—not to say drought—which the Province has to sustain. Referring to this subject, we find there is one more reason to be grateful in that we happen to have in Sir Arthur Gordon a Governor who has a discriminative and equitable Irrigation Policy—a policy which he fearlessly owns even as against the expressed views of his highest coadjutors. Admitting this much, we cannot go the length of endorsing every Irrigation work as either necessary or paying. The circumstances of the island have greatly changed since the gigantic works of irrigation whose very ruins strike us with wonder and awe were executed by the ancient rulers of Ceylon. Population has vanished, villages have disappeared and the works themselves have crumbled into ruins by long years of neglect, and, as the result, even the physical aspect of the country has undergone vast changes. People are not in hot haste to settle down in such places, in order to be swept by the fever-demon. We have always contended that smaller works of irrigation in large centres of population, as for instance the improvement of village tanks to begin with, will be a policy to which even the staunchest of Sir Arthur's opponents cannot and will not object.—"Ceylon Patriot."

Correspondence.

To the Editor.

TEA (A READY MONEY PRODUCT) VS. COFFEE
(WHICH NECESSITATED BORROWING).

Gampola, 10th January 1889.

DEAR MR. EDITOR.—Coffee vs. tea has been muddling in my brain for years. I begin to feel I have got out of the turbid waters into the crystal stream. My old love for coffee was strong; I partook of its prosperity and also of its adversity, and with matured years now over my head I can see the rock many of us were wrecked on. The hopeful, honest, hardworking planter (benefactor indeed), a man trying to make two blades of grass grow where only one grew before, is now sometimes pointed at by the cynic, who says my estate paid all through, had everyone been like me, &c., &c. Yes, cynic I say, had it been so, the blades of grass might have yearly grown fewer and fewer; you can't claim being a benefactor. So I must write you down cynic.

Well tea is a ready money business: every careful man can month by month balance his account and know to a cent how he stands.

Coffee was a credit business, and careful be you ever so much ("unless a cynic") who left things to chance, and nature, taking thankfully or otherwise what Providence sent him "and sticking to the bawbees," his small mind saying to him "put not thy money to usury."

Well, that coffee, which men toiled at late and early, waking and sleeping thoughts being, how can I honestly increase my returns, and call on mother earth to yield me her treasures; I will enrich her fertility by adding C. C. and B.s says one; another says I will build me cow houses and fill them with fattening kine, and have mountains of C. D. to apply: all this waking and sleeping thoughts required the wherewithal to bring them into practice. Poor but doomed coffee becoming somewhat worth 120 shillings a cwt., banks and capitalists even became imbued with the honest coffee planter's visions of beneficent earth, and freely handed him their hoarded wealth, which he hopefully converted into C. C. and B.s or C. D. and applied in full hope, all would soon be returned to him with usury. However in the midst of this enchanting vision another factor came in, whose name was H. V., and said, "You have been flagrantly transgressing God's laws, in spreading broadcast, over this land your coffee, and that only; you have been wantonly trying to nourish it with borrowed capital: neither are in accordance with divine rule. You have even transgressed nature's laws, of which I am a creature induced through your maladministration. I will in due time wipe out your transgressions, and set nature's balance right again." What became of all the sunk capital? Each one knows his own tale. After the long weary years he waited for the expected blossoming, which never came, with the banker's account rolling itself up, interest to capital. So much for the credit system. Had the earnest man been dealing with tea, they would have fought the enemy with fire and sword, and exterminated him, the deep roots of the tea would have sent up again new branches and in 3 months the debt would have been repaid, and month by month the banker's account would have received a credit instead of a debit entry. So much for coffee versus tea.

Let the new born prosperity not blind us to our errors of the past, feed and nourish your tea, bringing your best judgment to play; use your own capital feeling you are safe for a return.

as you have in hand a ready money concern. Use every means to send into market a real good honest article which will grow in public favour, and you will soon have seen the last of John Chinaman as a rival: British capital will then flow to India and Ceylon, instead of to China to purchase their adulterations.—Yours faithfully,
OLD PLANTER.

PEPPER GROWING.

Liskilleen, Neboda, 15th Jan.

DEAR SIR,—I was glad to read Mr. Martin's interesting letter on pepper. During my visit to Perak and Province Wellesley I visited several pepper gardens cultivated by Achinese who had left their country on account of the war, and had obtained free grants of land from the Straits Government.

They grow their vines on the dadap tree, planted about 8 to 10 feet apart.

This tree stands any amount of hacking, and they can therefore regulate the shading. This tree grows all about this district, and is used by the Sinhalese for fencing their gardens. It is very easily propagated from seed or cuttings. This may prove useful to some of your readers. I tried very hard to buy good [pepper] cuttings from the Achinese, but they would not sell at any price. They offered any amount of runners; these seem to keep on growing in a single shoot and won't bear.

They do not manure their vines; the reason they give is they run all to leaf.—Yours faithfully,
PRIOR S. PALMER.

KURAKKAN, RICE, AND OTHER FARINACEOUS
FOODS: THEIR RELATIVE MERITS.

Kandy, 15th Jan. 1889.

DEAR SIR,—I am glad to see that the food-supply of the people is now under discussion, and I think we have reason to be thankful to Mr. Borron for his letter which manifests a kindly interest in the welfare of the inhabitants of this island.

In your article of the 12th inst., on Kurakkan as a Food," you are apparently inclined to think that some medical men have a prejudice against the consumption of this millet, and that they are of opinion that it is "a direct cause of the wasting and loathsome disease known as *parangi*."

In February 1868, as Colonial Surgeon of Jaffna, I was appointed "to report on the subject of the depopulation of the Wannai district as recommended by the Irrigation Commission." My instructions were, "the disease commonly known by the term *parangi*, will naturally become the special object of your inquiry, its history, the variety of its symptoms from its earliest stages to its termination, its influence on the health and longevity of the population, its predisposing causes in regard to the habits, customs, diet, &c. of the people," &c. In carrying out the inquiry, I found that I was able to get little assistance from previous writers. "Marshall's Notes on the Medical Topography of Ceylon" and "Ainslie's Materia India" were about the only books in which I could find any information. My report "On the Depopulation of the Wannai District" was sent to the P. C. M. O. in August 1868; it was laid before the Legislative Council and ordered to be printed. It has been reprinted as an appendix to Dr. Kynsey's exhaustive report on "The Parangi Disease of Ceylon," one of the sessional papers for 1881.

I was inclined to consider *parangi disease* partly as the result of a constitutional vice; but the more influential causes were stated as follows:— "But while expressing my conviction that *parangi disease* is to some extent a constitutional vice, I believe that other causes have a powerful influence on the development of the symptoms and aggravation of the complaint. It requires

little observation to satisfy one that the inhabitants of the Wannu are surrounded by the most unhealthy influences. Long periods of drought lead to the use of water, for drinking and other purposes, which would nauseate ordinary stomachs, and to the absolute neglect of personal cleanliness. The bodies and clothes of the people are filthy in the extreme. The huts in which they live are close and confined, and no doubt favour the spread of the disease. Water is obtained from tanks, the area of which is large, but the depth of water small. These tanks not only supply drinking water; but people bathe in them, and herds of buffaloes lie in them during the heat of the day. The water consequently is thick and muddy, full of organic matter, and, if kept for a little time, decomposes and becomes offensive. Insufficient food, or the use of unwholesome food, is another source of the deprivation of the blood, which probably plays its part in the production of the disease. The people themselves term several articles of diet ordinarily consumed by them *kiranti food*. Although I am not able to speak from much experience, I believe there is no reason to doubt the nutritive qualities of kurakkan; but I suspect the people are right in thinking that it is heating, and that it lays the foundation of disorders of the digestive organs and of the skin, a result attributed also to the constant use of oatmeal and other farinaceous food."

From the preceding extract, it will be seen that my opinion regarding parangi disease is that it is due to a combination of causes, and not simply to the use of a particular kind of food. It is, however, certain that the food of the people is both insufficient and unvariable. As regards diet, variety is as important as the nutritive quality of food substances, and the constant use of an article may lead to injurious consequences. Dr. Johnson defined *oats* as "a grain which in England is generally given to horses, but in Scotland supports the people," and the happy retort was made "Where else will you see *such horses* and *such men*?" I believe all are agreed that oatmeal is an excellent sustenance, and there are many who deplore that it is being displaced by wheat in Scotland. Medical men are well aware of the connexion of disorders of the skin with indigestion. Cullen, an old but excellent writer on medicine, has, in his work on the Practice of Physic, a chapter "on the pyrosis, or what is named in Scotland the water-brash"; and he says of it that "it is a disease frequent among people in lower life, but occurs also, though more rarely, in people of better condition." The complaint is attended with heartburn, and is ascribed to the large employment of farinaceous substances, and especially of oatmeal.

Mr. Borron compares the dry grains of this country to oatmeal, and says of kurakkan: "It is sustaining, nourishing and wholesome," and that persons accustomed to oatmeal porridge "will find it pleasant also." The nutritive value of the millets is not denied; but bad consequences may arise from their constant use, particularly as rice is said to be a luxury almost unknown in some places in the interior. Dr. King, in his "Madras Manual of Hygiene,"* says of *oatmeal*: "Weight for weight, it contains more nutritive material than wheat-flour, to which it is inferior only in starch, exceeding it in fat more especially." Of the *millets* (or so-called *dry grains*, from their mode of cultivation without artificial irrigation), he says: "As a class they form a more nutritious dietary than rice"; but, he adds: "in the case of *ragee* (ku-

* The Madras Manual was handed by us to Dr. Kynsey, and he had it reprinted. We suppose the opinion regarding oatmeal occurs in the Manual.—Ed.

rakkan) more especially *complete comminution and careful boiling* are necessary to obviate indigestibility, leading to diarrhoea and insufficient nutrition."

Some years ago it became a matter of practical importance, in connection with our jails, to determine what constitutes a suitable dietary for labouring men. I know that my friend, the late Dr. Dickman, entertained a high opinion of the nutritive value of kurakkan; but I was not aware that he recommended it as an article of diet for prisoners. In the report of Dr. Charsley, P. C. M. O., for 1863, the following passage occurs: "This year has been memorable for the introduction of what is termed Penal Diet among the prisoners on the recommendation of the Jail Commission." This diet consisted only of rice with salt for breakfast, and for dinner, with a little rice congee or gruel in the morning before going out for work; and it was enforced for the first ten days of every month for the first six months of imprisonment. The prisoners were to be on ordinary diet for the remaining two-thirds of the month. Medical officers were directed carefully to watch the effects of the diet. In a short time unfavourable reports were made from Kandy (probably by Dr. Dickman) and from Hambantota, and an unusual amount of prevalence of bowel complaint was ascribed to the lowering of the system by insufficient diet. It was represented that "the diet, from its deficiency in nitrogenous principles, cannot be enforced without permanent injury to the health of the prisoners." The Penal Diet was afterwards improved and made more nourishing.

I agree with you that kurakkan must be more sustaining than rice; but the latter is more easily prepared and "it is generally regarded in full quantity, as the standard of comfortable living in large portions of India." The prisoners in our jails, fed on rice, soon become sleek and fat, and the general impression is that they are well-fed, able-bodied men; but the fact is known to medical officers that in illness the recuperative powers are deficient, and it is a matter of anxiety to keep down sickness and mortality in our jails. In a paper published in 1853 in the *Ceylon Medical Miscellany*, "on burning of the feet," I threw out a suspicion that there was a scorbutic tendency among the prisoners at Welikada from their being fed on rice with too little animal food. Some years afterwards Drs. Kynsey and Koch were satisfied that scurvy existed in the Colombo jails, and they recommended that the diet of the prisoners should be made more nourishing by the addition of nitrogenous or flesh-forming substances.

Wheat, although the best of the cereals, is considered to be deficient in anti-scorbutic salts. There is much less of flesh-forming substance (gluten) in rice than in wheat; but it has a larger amount of fat-forming or heat-giving substances, and as it is easily digestible, it is for good reasons the staple food in hot climates. As it is deficient in the nitrogenous element, meat or fish or dal (as in India) has to be added. The Hindus, who feed almost entirely on rice, are often attacked with sloughing of the cornea, an affection which was not very uncommon in prisoners here in former days after a short illness.

What I have written is a humble contribution to the subject of the relative value of rice and kurakkan, as food for the people. The extinction of malaria and the increase of food supply in certain parts of the island are matters deserving of consideration, and it is satisfactory to find earnest minds exercised as to the best means of advancing the welfare of the inhabitants.—Your obedient servant,

JAMES LOOS, M.D.,
Retired Colonial Surgeon.

TOBACCO PLANTING.

P'n. bonne Intention, East Coast, Demerara, British Guiana, S, A, November 24th 1888.
